Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

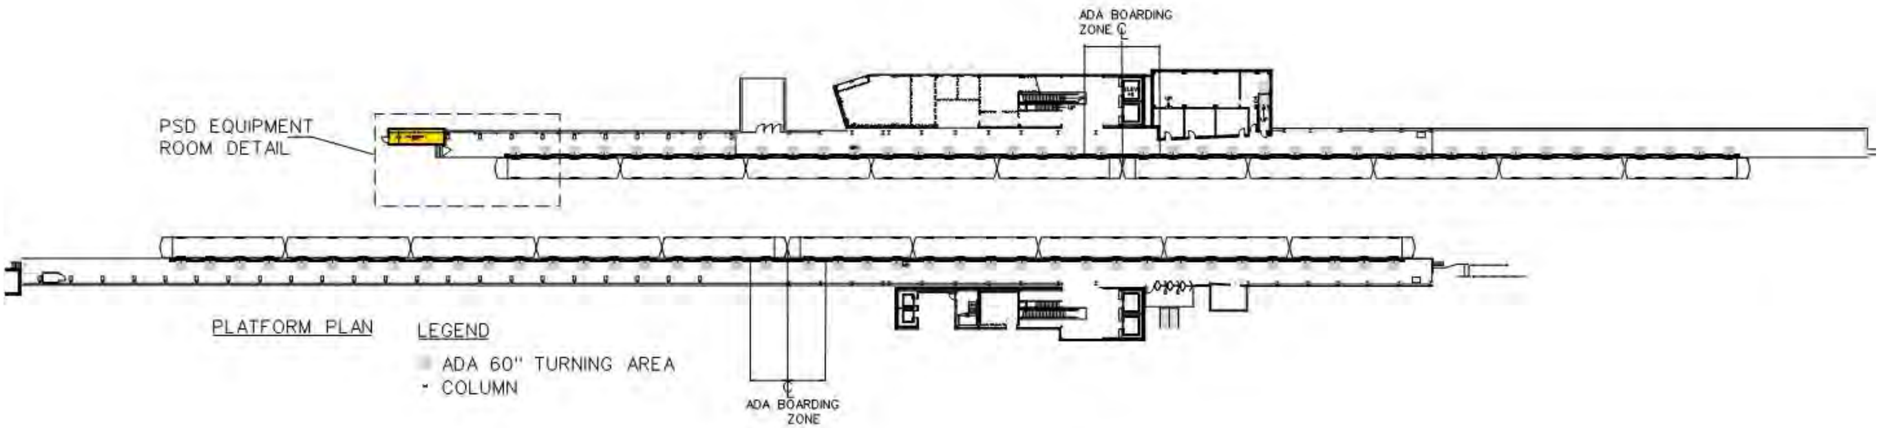

***Figure 1** – Overall plan*
Howard Beach Station

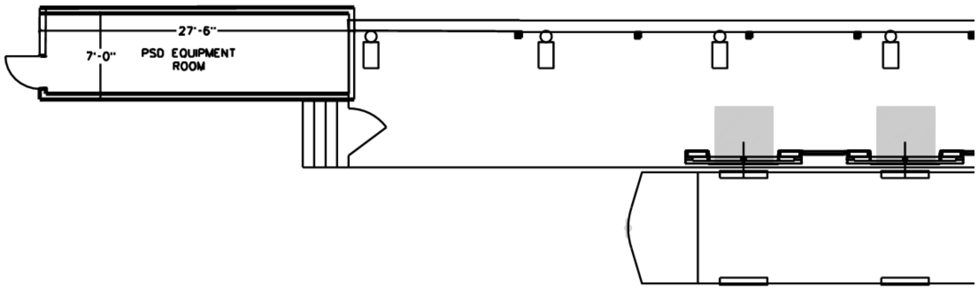

Figure 1 *– Equipment Room plan*
Howard Beach Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the back of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Howard Beach Airtrain
Peak Demand Load from ConEd Report, (kW)	51.0
Apparent Power (kVA)	63.7
Station Peak Demand Load, Max Current, (A)	177.0
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	372
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	828
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 1200A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service.

Table 1. Power Capacity Analysis

Station Power Capacity Analysis (Reserve Service)

Station Name	Howard Beach Airtrain
Peak Demand Load from ConEd Report, (kW)	48.0
Apparent Power (kVA)	60.0
Station Peak Demand Load, Max Current, (A)	166.7
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	361
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	839
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 1200A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service.

Howard Beach - Airtrain Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.1M to install APGs (See Appendix E).

1.56 – MR 199 | Broad Channel Station

Summary: *Broad Channel Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Broad Channel Station is an on-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths are 12'-10" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 50% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 50% of the station platform length. Full height PSDs require a top connection to brace against wind load.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the south end of the southbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.7M to install APGs (See Appendix E).

1.60 – MR 203 | Rockaway Park Station

Summary: *Rockaway Park Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. The Rockaway Park Shuttle Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Rockaway Park Station is an elevated station with one straight center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are two rows of columns at the canopy at 5'-6" from the platform edge. The platform width is 27'-8" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 50% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 50% of the station platform length. Full height PSDs require a top connection to brace against wind load.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the north end of the platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

***Figure 3** – General platform view*
Rockaway Park Station

Historic Restrictions:
The Rockaway Park station is a historically designated property. As such, design will require review by the New York State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.8M to install APGs (See Appendix E).

1.61 – MR 204 | Beach 67th Street Station

Summary: *Beach 67th Street Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Beach 67th Street Station is an elevated station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths are 10'-10" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 60% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 40% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the center of the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

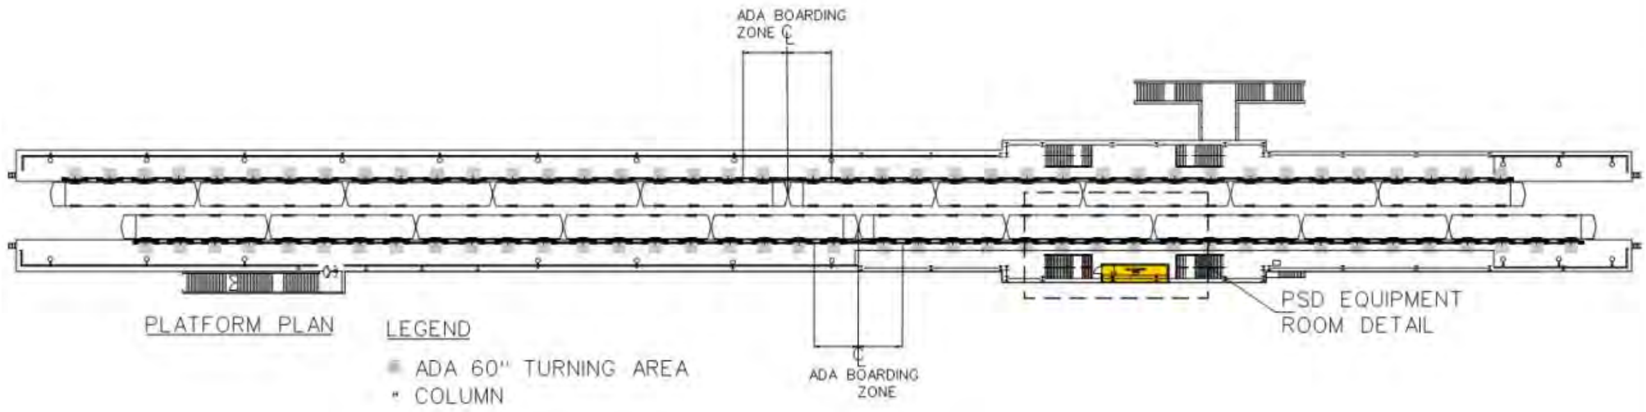

Figure 1 *– Overall plan*
Beach 67th Street Station

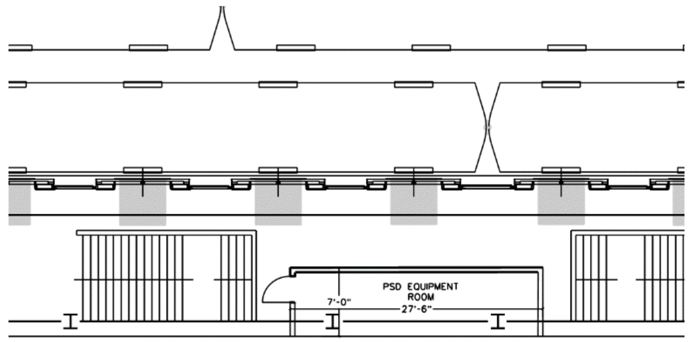

***Figure 2** – PSD Equipment Room Detail*
Beach 67th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the back of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Beach 67th St. Gaston Ave
Peak Demand Load from ConEd Report, (kW)	33.0
Apparent Power (kVA)	41.3
Station Peak Demand Load, Max Current, (A)	114.6
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	309
Station Service Power Capacity, (A)	400
Service Spare Capacity, (A)	91
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 400A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. Utility is LIPA.

Station Power Capacity Analysis (Reserve Service)

Station Name	Beach 67th St. Gaston Ave
Peak Demand Load from ConEd Report, (kW)	7.0
Apparent Power (kVA)	8.8
Station Peak Demand Load, Max Current, (A)	24.3
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	219
Station Service Power Capacity, (A)	400
Service Spare Capacity, (A)	181
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 400A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. Utility is LIPA.

Table 2. Power Capacity Analysis

Figure 3 *– General platform view*
Beach 67th Street Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.1M to install APGs (See Appendix E).

1.62 – MR 205 | Beach 60th Street Station

Summary: *Beach 60th Street Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Beach 60th Street Station is an elevated station with two nearly straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths are 10'-8" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 50% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 50% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the south end of the southbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are nearly tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

The total cost for this station is estimated to be $33.5M to install APGs (See Appendix E).

Table of Contents

1.66 – MR 209 | Far Rockaway / Mott Avenue Station

Summary: *Far Rockaway / Mott Avenue Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Far Rockaway / Mott Avenue Station is an elevated station with one straight center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are two rows columns at the canopy, at 4'-4" from the platform edge. The platform width is 24'-6" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 60% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 40% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the center of the platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

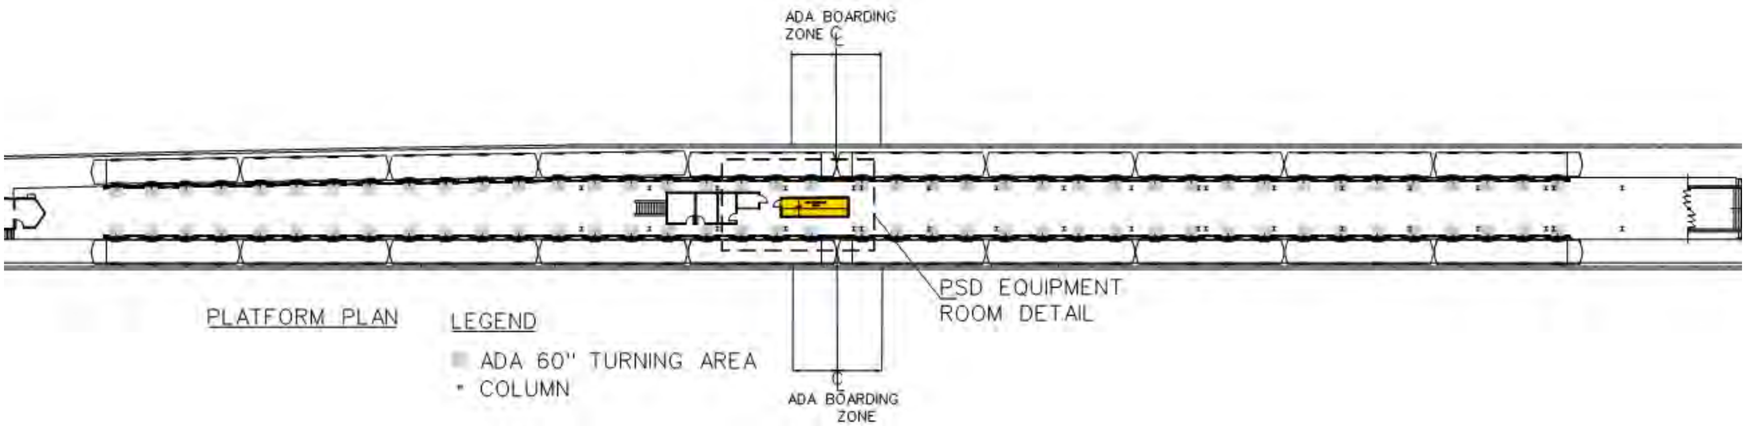

Figure 1 *– Overall plan*
Far Rockaway / Mott Ave Station

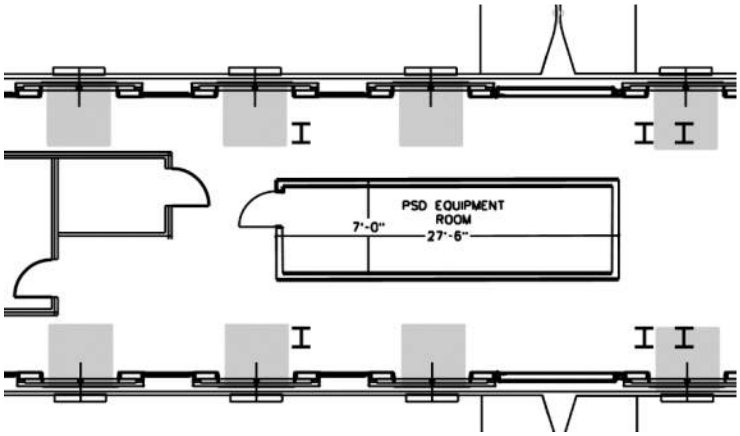

Figure 2 *– PSD Equipment Room Detail*
Far Rockaway / Mott Ave Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the center of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.4M to install APGs (See Appendix E).

Appendices: Table of Contents

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> - *a. Column location in relation to the platform edge*
> - *b. Platform edge clearance adjacent to stairs and other impediments*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

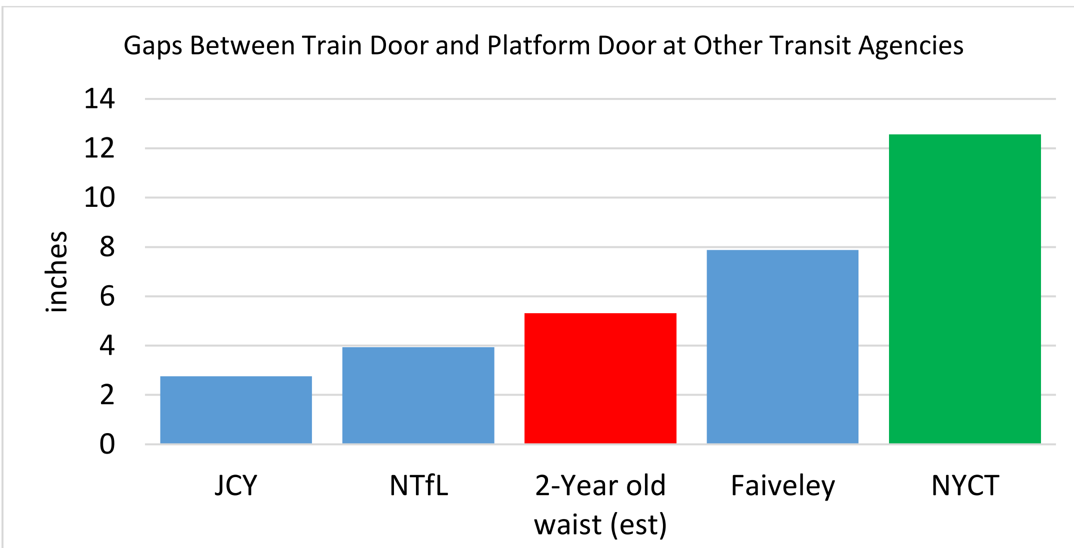

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

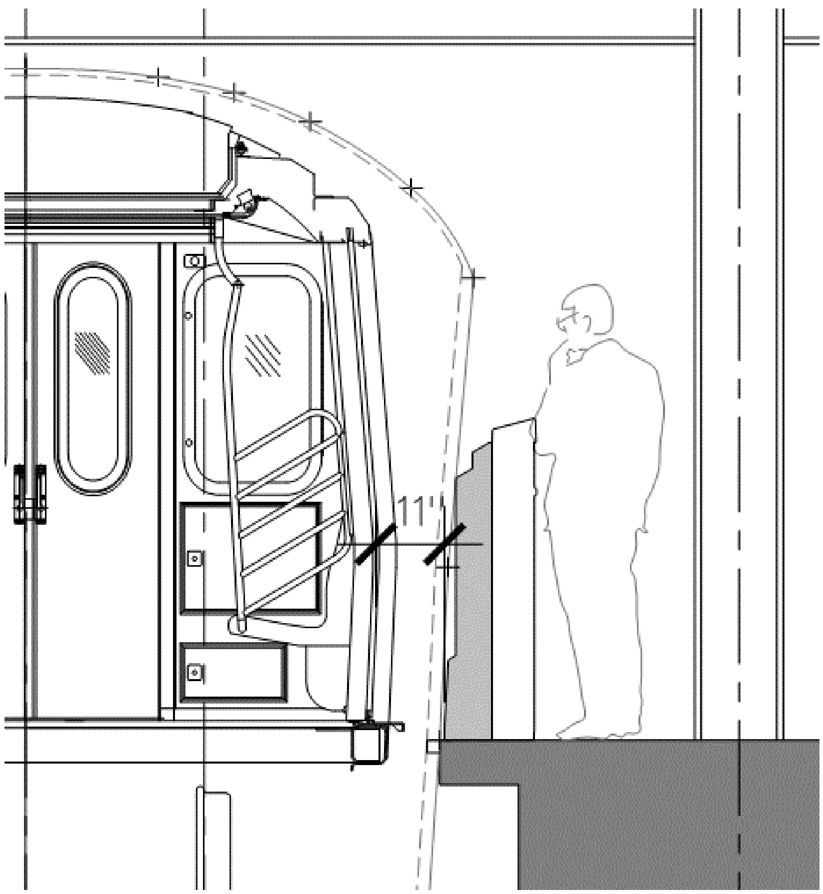

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

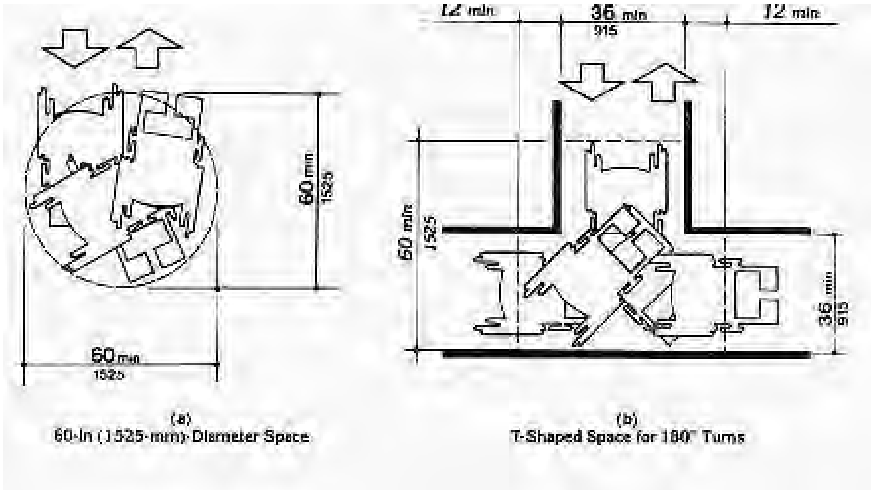
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*

The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

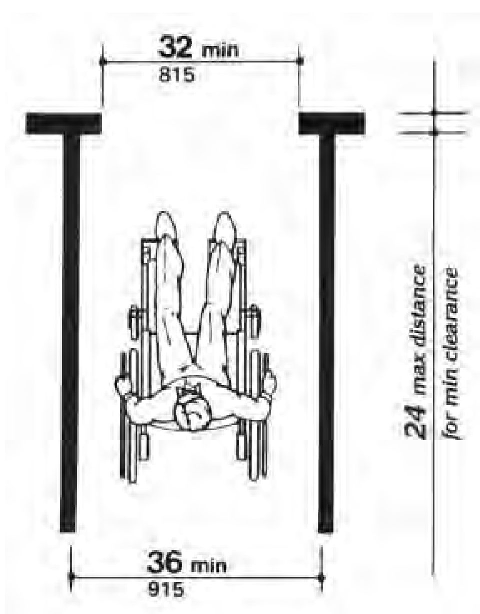


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

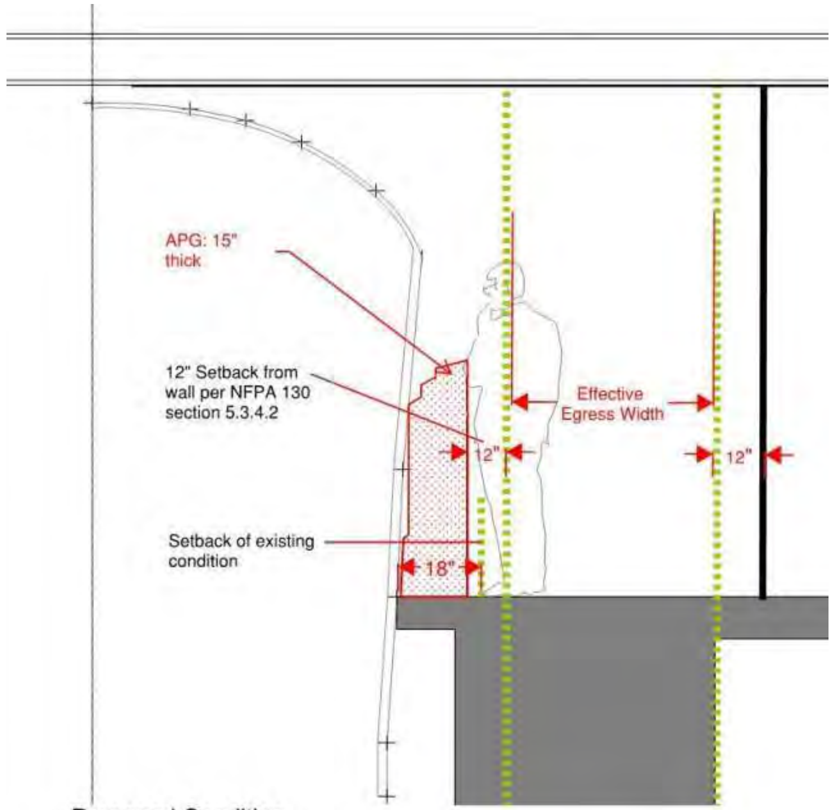
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
  1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
  2. Transmit OPEN COMMAND from the train to the wayside.
  3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
  4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
  5. Transmit OPEN COMMAND to PSD/ASG controller.

C. Dwell during passenger boarding/alighting

D. Close doors
  6. Transit CLOSE COMMAND from train to wayside.
  8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
  7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
  9. Transmit DOOR CLOSED SIGNAL from wayside to train.
  10. Accelerate from station when safe to do so.

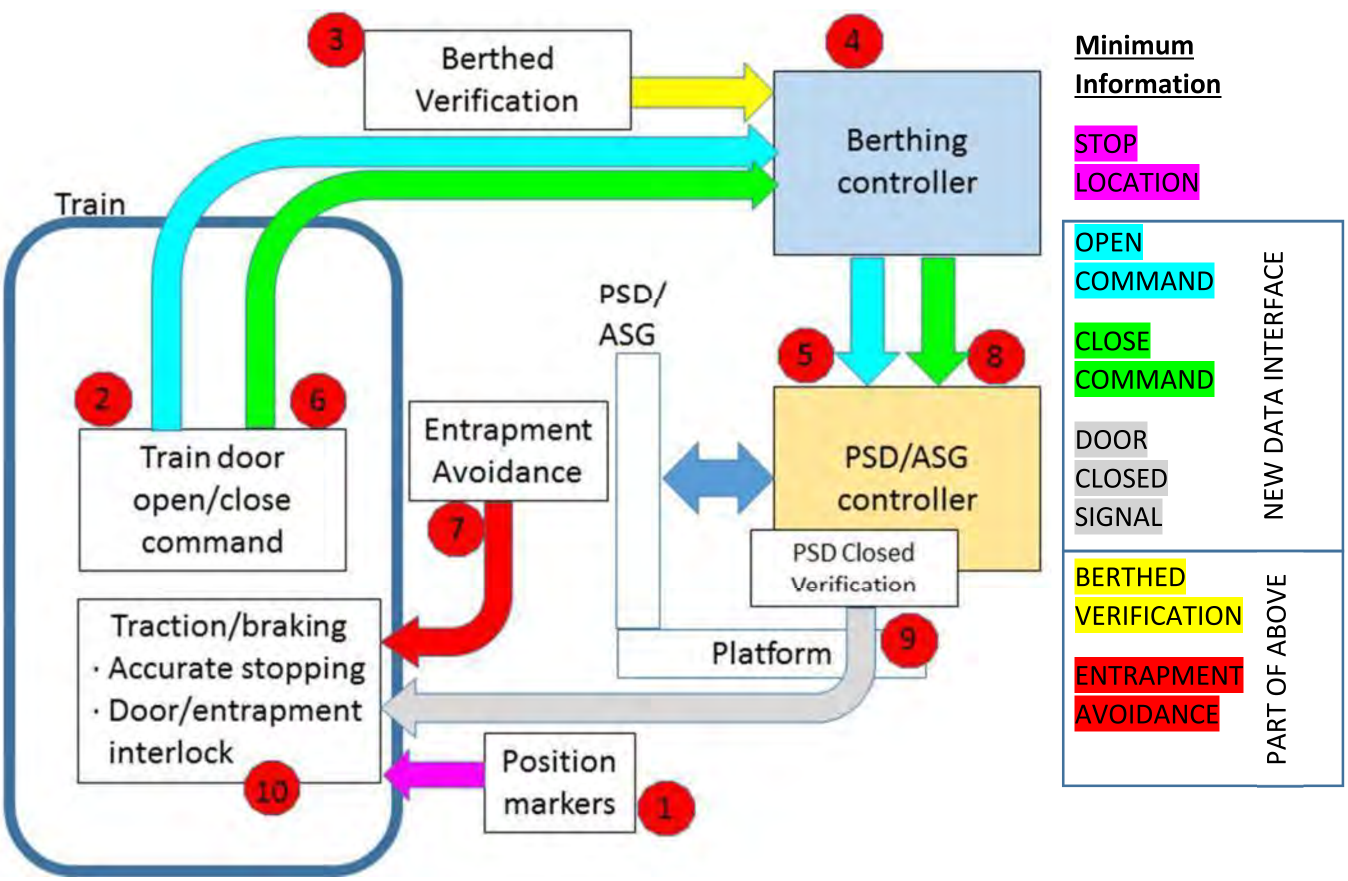

Table of Contents Appendix Table of Contents

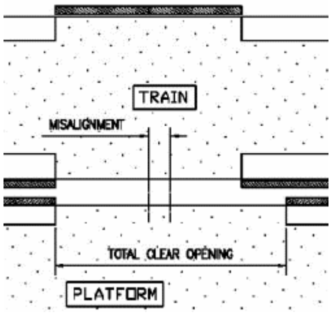
Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

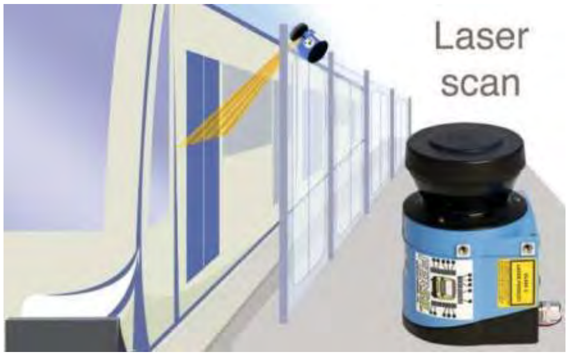
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

Table of Contents Appendix Table of Contents

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

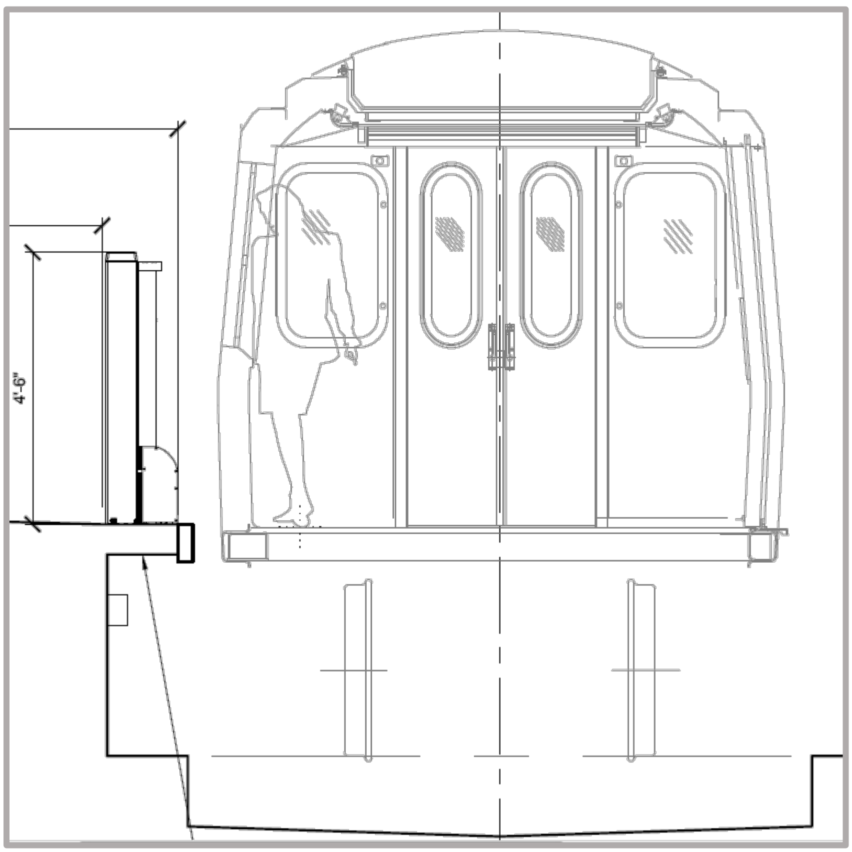


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

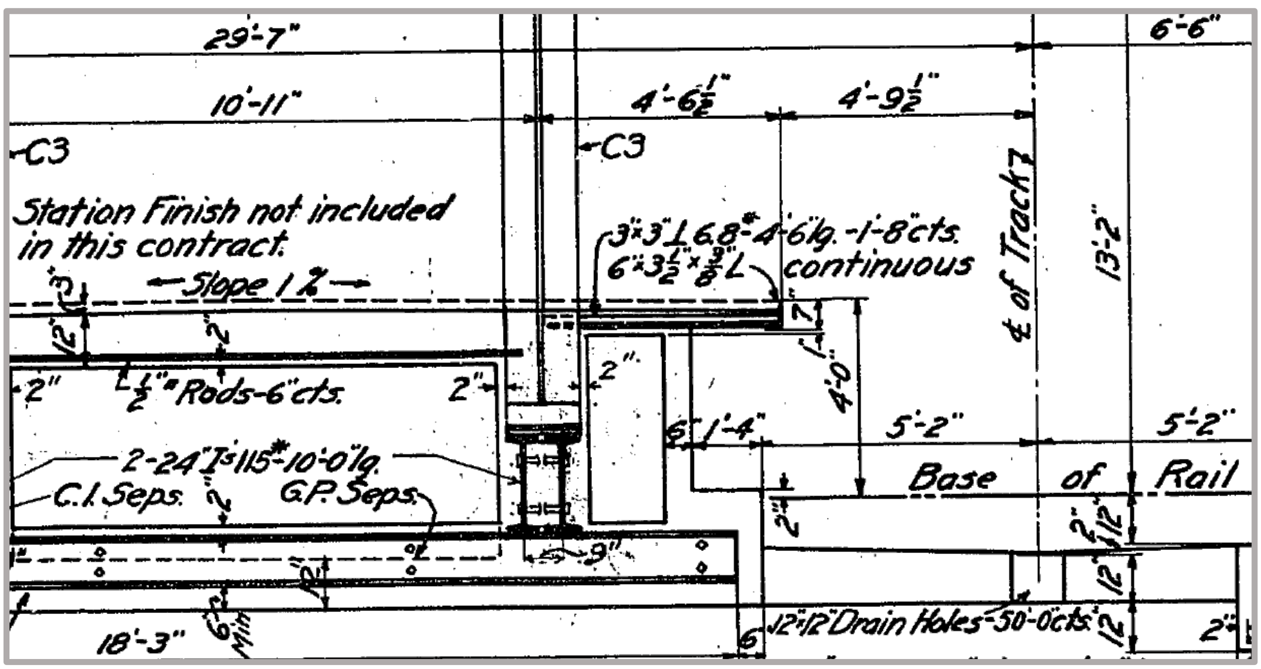

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

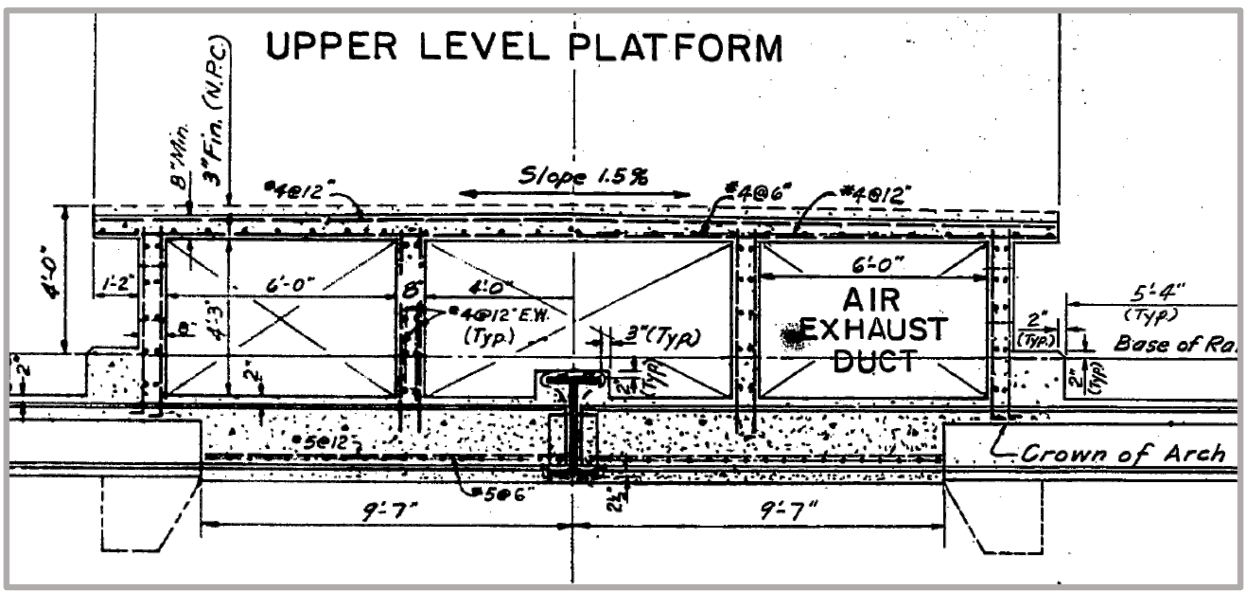

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

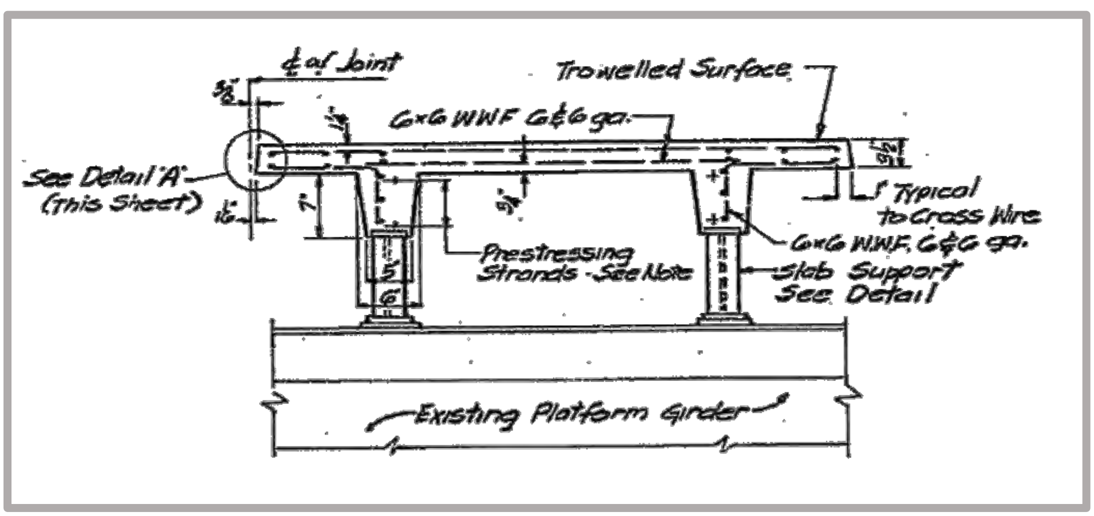

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

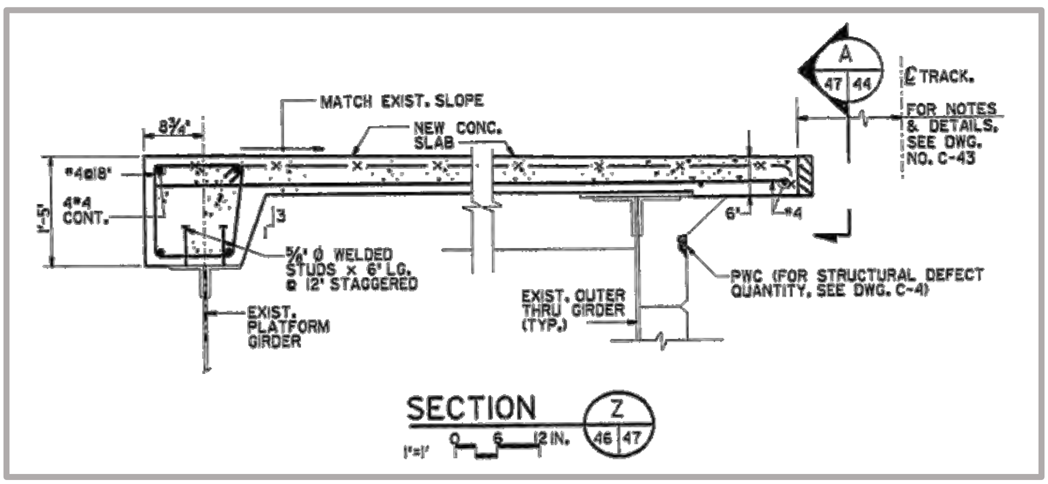

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

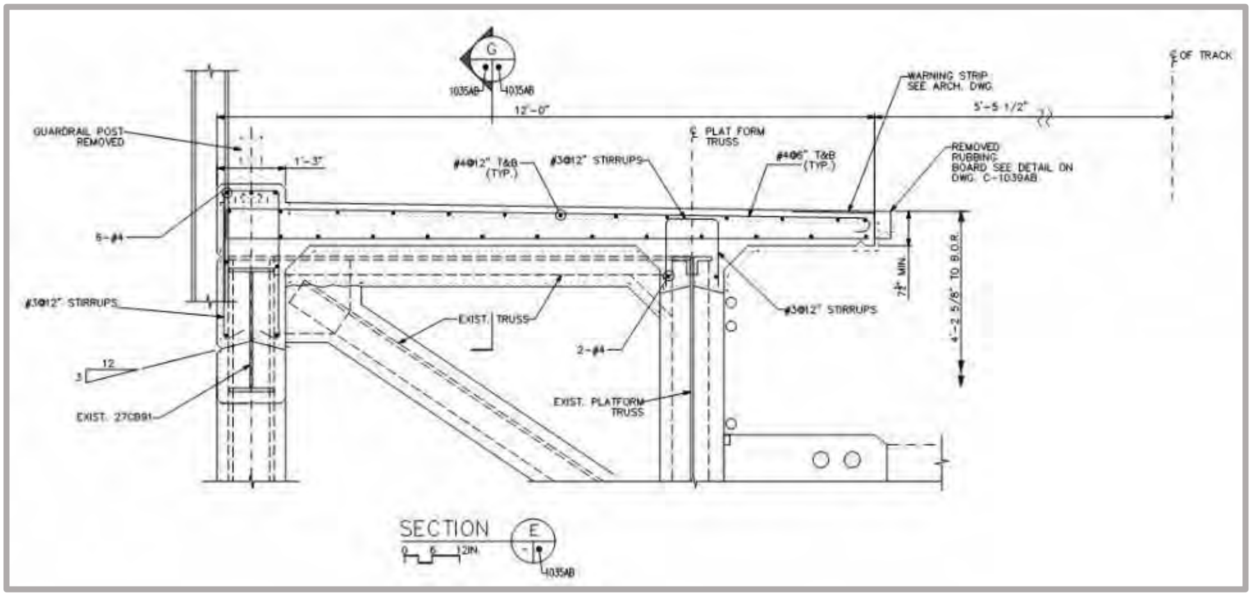

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

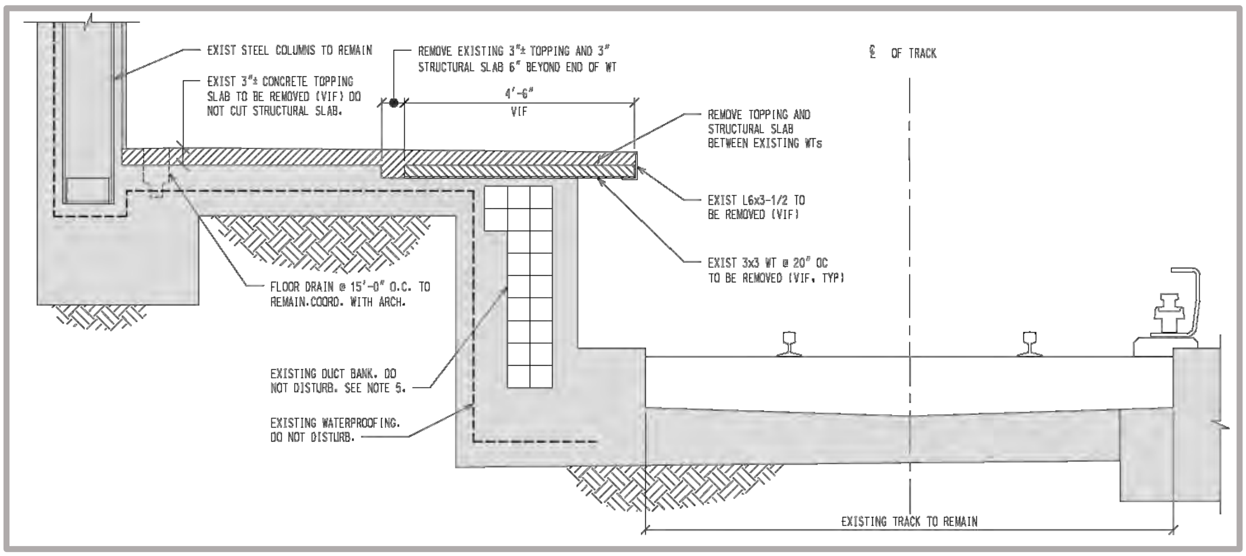

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

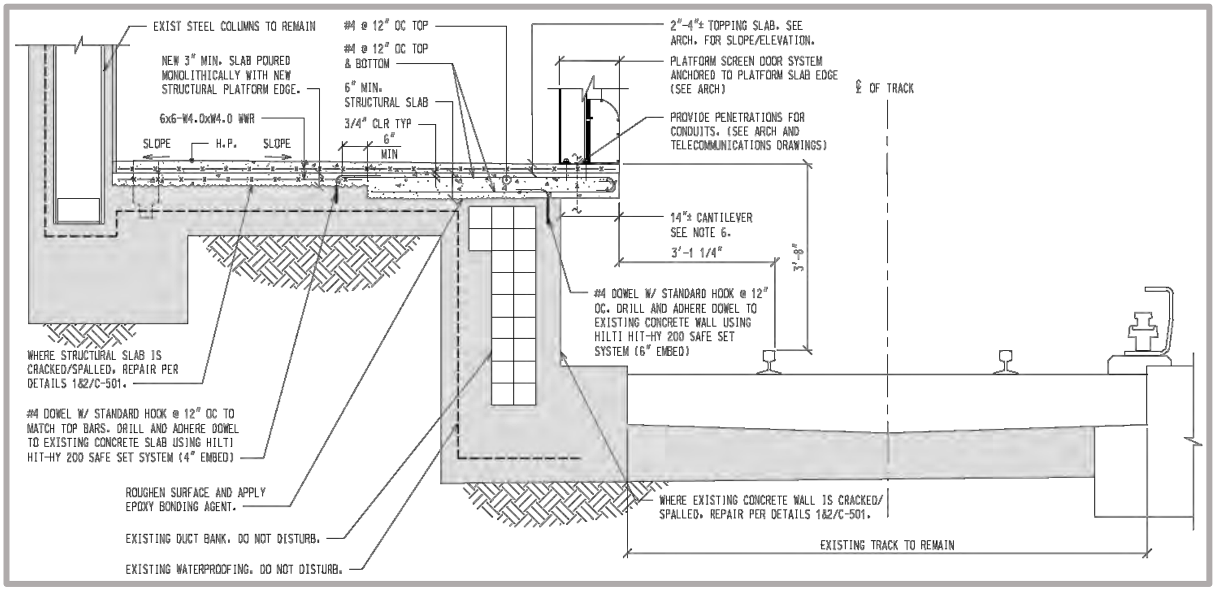

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

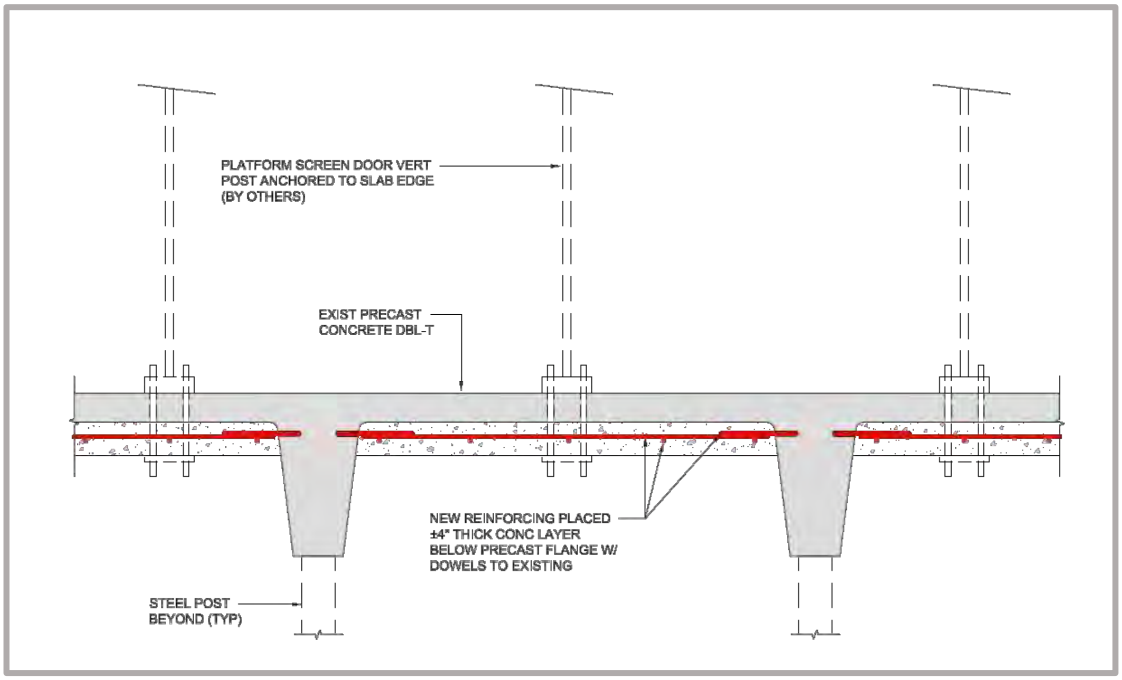

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

MTA/NYCT

June 24, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

MTA/NYCT

June 24, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : DYCKMAN ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	653	LF		
5	LENGTH OF THE PLATFORM EDGE =	653	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,306**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,306	LF	7	9,142
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,530	SF	12	78,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,308	EA	25	32,700
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,308	EA	25	32,700
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,306	LF	95	124,070
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,306	LF	15	19,590
26	Remove existing platform tiles	1,306	LF	12	15,672
27	Sawcut existing topping concrete at perimeter of removal area	1,306	LF	5	6,530
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,836	SF	8	62,688
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,306	SF	15	19,590

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : DYCKMAN ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	480	SF	15	7,200
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-0"]**				
37	Build off existing mezzanine slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	41	LF	90	3,690
39	CMU Wall for equipment room	410	SF	45	18,450
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	189	SF	30	5,670
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	410	SF	40	16,400
45	Mosaic Band to match existing - Assuming 8" high	41	LF	120	4,920
46	Concrete cove to match existing	41	LF	20	820
47	Interior Wall Finish - Paint	680	SF	5	3,400
48	Allow for Misc. floor & ceiling finishes	189	SF	15	2,835
49	Allow for 4" thick concrete pads for equipment	47	SF	20	945
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,592	SF	750	1,944,000
61	Spare Parts - Approx. 10% of Material Cost	1	LS	243,300	243,300
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : DYCKMAN ST

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,306	LF	60	78,360
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	356	LF	60	21,360
75	Reserve power to PSD Room from EDR [Conduit & Cable]	406	LF	60	24,360
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

147	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	(78)	EA	10,500	(819,000)
148	Double egress/service gate in the center of the platform; #1 per Platform	(2)	EA	20,000	(40,000)
149	Platform End Gates (PEGs)	(4)	EA	13,000	(52,000)
150	Fixed Panels including framing and support; 4'-6" High	(2,592)	SF	750	(1,944,000)
151	Spare Parts - Approx. 10% of Material Cost	(1)	LS	243,300	(243,300)
152	Platform Edge Reconstruction work	(1)	LS	588,960	(588,960)
153	Remove allowance for cast in sleeves for LV & HV power	(328)	EA	110	(36,080)
154	Conduit running under Platform Edge	(1,306)	LF	30	(39,180)
155					
156	Allow loss of production to work at night say 50%	1	LS	1,156,263	1,156,263
157					
158	PREMIUM ASSOCIATED WITH PSD's				$ 5,010,472

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 190TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	660	LF		
5	LENGTH OF THE PLATFORM EDGE =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 15'-8" wide	774	SF	8	6,189
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 190TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	774	SF	15	11,604
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,655	SF	750	1,991,250
61	Spare Parts - Approx. 10% of Material Cost	1	LS	246,135	246,135
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 175TH STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE =	657	LF		
5	LENGTH OF THE PLATFORM EDGE =	657	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,314**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,314	LF	7	9,195
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,568	SF	12	78,810
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,316	EA	25	32,888
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,316	EA	25	32,888
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,314	LF	95	124,783
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,314	LF	15	19,703
26	Remove existing platform tiles	1,314	LF	12	15,762
27	Sawcut existing topping concrete at perimeter of removal area	1,314	LF	5	6,568
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,881	SF	8	63,048
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 19'-0" wide	1,040	SF	8	8,320
30	New Work				
31	New concrete topping to match existing	1,314	SF	15	19,703
32	New concrete topping at ADA boarding area to match existing	1,040	SF	15	15,600

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 135TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	598	LF		
5	LENGTH OF THE PLATFORM EDGE =	598	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,196**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,196	LF	7	8,372
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,980	SF	12	71,760
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	120	CY	2,500	300,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,198	EA	25	29,950
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,198	EA	25	29,950
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,196	LF	95	113,620
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,196	LF	15	17,940
26	Remove existing platform tiles	1,196	LF	12	14,352
27	Sawcut existing topping concrete at perimeter of removal area	1,196	LF	5	5,980
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,176	SF	8	57,408
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 5'-9" wide	460	SF	8	3,680
30	New Work				
31	New concrete topping to match existing	1,196	SF	15	17,940

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 125TH ST. NICHOLAS AVE. - A TRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,268	LF	60	76,080
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	300	LF	60	18,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	350	LF	60	21,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 125TH ST. NICHOLAS AVE. - C TRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (C - TRAIN) =	634	LF		
5	LENGTH OF THE PLATFORM EDGE (C - TRAIN) =	634	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,268**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,268	LF	7	8,876
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,340	SF	12	76,080
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	128	CY	2,500	320,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,270	EA	25	31,750
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,270	EA	25	31,750
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,268	LF	95	120,460
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,268	LF	15	19,020
26	Remove existing platform tiles	1,268	LF	12	15,216
27	Sawcut existing topping concrete at perimeter of removal area	1,268	LF	5	6,340
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,608	SF	8	60,864
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 7'-0" wide	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,268	SF	15	19,020

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 125TH ST. NICHOLAS AVE. - C TRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	560	SF	15	8,400
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room - C Train [7'-0" x 27'-6"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,421	SF	750	1,815,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	235,605	235,605
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : 50TH STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	660	LF		
5	LENGTH OF THE PLATFORM EDGE =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: 34TH STREET PENN STATION

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: 23RD STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,320	LF	60	79,200
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Rooms from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	Allowance for power to cross tracks to opposite platform; 4 Tracks between Platforms	1	LS	35,000	35,000
77	No allowance for new lighting as if APG's are used		Note		EXCL.
78	Grounding				
79	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
80	MISC				
81	Testing and commissioning	1	EA	30,000	30,000
82	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
83					
84	**Communications**				
85	FA System				
86	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
87	CCTV coverage				
88	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
89	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
90	Berthing Technology Sensors				
91	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
92	Train Door Detection System				
93	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
94	Entrapment concerns				
95	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
96	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
97	Engineering and Testing	1,000	Hrs	160	159,930
98	Centralized monitoring/control				
99	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
100	MISC				
101	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: 14TH STREET - A TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	670	LF		
5	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	670	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,340**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,340	LF	7	9,380
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,700	SF	12	80,400
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,342	EA	25	33,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,342	EA	25	33,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,340	LF	95	127,300
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,340	LF	15	20,100
26	Remove existing platform tiles	1,340	LF	12	16,080
27	Sawcut existing topping concrete at perimeter of removal area	1,340	LF	5	6,700
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,040	SF	8	64,320
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,340	SF	15	20,100

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: 14TH STREET - A TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room - A Train [6'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	61	LF	90	5,445
39	CMU Wall for equipment room	605	SF	45	27,225
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	176	SF	30	5,265
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	605	SF	40	24,200
45	Mosaic Band to match existing - Assuming 8" high	61	LF	120	7,260
46	Concrete cove to match existing	61	LF	20	1,210
47	Interior Wall Finish - Paint	605	SF	5	3,025
48	Allow for Misc. floor & ceiling finishes	176	SF	15	2,633
49	Allow for 4" thick concrete pads for equipment	44	SF	20	878
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,745	SF	750	2,058,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	250,185	250,185
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: WEST 4TH STREET - A TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	660	LF		
5	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	679	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,339**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,339	LF	7	9,373
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,695	SF	12	80,340
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,341	EA	25	33,525
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,341	EA	25	33,525
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,339	LF	95	127,205
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,339	LF	15	20,085
26	Remove existing platform tiles	1,339	LF	12	16,068
27	Sawcut existing topping concrete at perimeter of removal area	1,339	LF	5	6,695
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,034	SF	8	64,272
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	780	SF	8	6,240
30	New Work				
31	New concrete topping to match existing	1,339	SF	15	20,085

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION: WEST 4TH STREET - C TRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (C - TRAIN) =	660	LF		
5	LENGTH OF THE PLATFORM EDGE (C - TRAIN) =	679	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,339**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,339	LF	7	9,373
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,695	SF	12	80,340
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,341	EA	25	33,525
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,341	EA	25	33,525

24-Jun-19

STATION: CANAL STREET - A TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	653	LF		
5	LENGTH OF THE PLATFORM EDGE (A - TRAIN) =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,313**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,313	LF	7	9,191
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,565	SF	12	78,780
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,315	EA	25	32,875
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,315	EA	25	32,875
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,313	LF	95	124,735
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,313	LF	15	19,695
26	Remove existing platform tiles	1,313	LF	12	15,756
27	Sawcut existing topping concrete at perimeter of removal area	1,313	LF	5	6,565
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,878	SF	8	63,024
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,313	SF	15	19,695

24-Jun-19

STATION : FULTON ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	658	LF		
5	LENGTH OF THE PLATFORM EDGE =	658	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,316**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,316	LF	7	9,212
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,580	SF	12	78,960
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,318	EA	25	32,950
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,318	EA	25	32,950
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,316	LF	95	125,020
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,316	LF	15	19,740
26	Remove existing platform tiles	1,316	LF	12	15,792
27	Sawcut existing topping concrete at perimeter of removal area	1,316	LF	5	6,580
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,896	SF	8	63,168
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 22'-0" wide strip	1,280	SF	8	10,240
30	New Work				
31	New concrete topping to match existing	1,316	SF	15	19,740

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : LAFAYETTE AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	660	LF		
5	LENGTH OF THE PLATFORM EDGE =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 9'-8" wide	294	SF	8	2,349
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

74	Power to PSD Room from EDR [Conduit & Cable]	600	LF	60	36,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	650	LF	60	39,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : FRANKLIN AVENUE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	662	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	662	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,324**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,324	LF	7	9,268
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,620	SF	12	79,440
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,326	EA	25	33,150
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,326	EA	25	33,150
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,324	LF	95	125,780
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,324	LF	15	19,860
26	Remove existing platform tiles	1,324	LF	12	15,888
27	Sawcut existing topping concrete at perimeter of removal area	1,324	LF	5	6,620
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,944	SF	8	63,552
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 9'-8" wide	294	SF	8	2,349
30	New Work				
31	New concrete topping to match existing	1,324	SF	15	19,860
32	New concrete topping at ADA boarding area to match existing	294	SF	15	4,404

STATION : NOSTRAND AVENUE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE [SOUTH BOUND] =	660	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : KINGSTON THROOP AVENUES

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	660	LF		
5	LENGTH OF THE PLATFORM EDGE =	618	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,278**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,278	LF	7	8,946
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,390	SF	12	76,680
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	129	CY	2,500	322,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,280	EA	25	32,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,280	EA	25	32,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,278	LF	95	121,410
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,278	LF	15	19,170

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : UTICA AVENUE - A Train

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE (A Train side) =	610	LF		
5	LENGTH OF THE PLATFORM EDGE (A Train side) =	610	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,220**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,220	LF	7	8,540
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,100	SF	12	73,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	123	CY	2,500	307,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,222	EA	25	30,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,222	EA	25	30,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,220	LF	95	115,900
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,220	LF	15	18,300
26	Remove existing platform tiles	1,220	LF	12	14,640
27	Sawcut existing topping concrete at perimeter of removal area	1,220	LF	5	6,100
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,320	SF	8	58,560
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 27'-8" wide	1,734	SF	8	13,869
30	New Work				
31	New concrete topping to match existing	1,220	SF	15	18,300

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : RALPH AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	660	LF		
5	LENGTH OF THE PLATFORM EDGE =	618	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,278**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,278	LF	7	8,946
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,390	SF	12	76,680
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	129	CY	2,500	322,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,280	EA	25	32,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,280	EA	25	32,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,278	LF	95	121,410
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,278	LF	15	19,170
26	Remove existing platform tiles	1,278	LF	12	15,336
27	Sawcut existing topping concrete at perimeter of removal area	1,278	LF	5	6,390
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,668	SF	8	61,344
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 9'-8" wide strip	294	SF	8	2,349
30	New Work				
31	New concrete topping to match existing	1,278	SF	15	19,170

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : BROADWAY JCT/EAST NY - A TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [A - TRAIN] =	610	LF		
5	LENGTH OF THE PLATFORM EDGE [A - TRAIN] =	610	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,220**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,220	LF	7	8,540
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,100	SF	12	73,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	123	CY	2,500	307,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,222	EA	25	30,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,222	EA	25	30,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,220	LF	95	115,900
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,220	LF	15	18,300
26	Remove existing platform tiles	1,220	LF	12	14,640
27	Sawcut existing topping concrete at perimeter of removal area	1,220	LF	5	6,100
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,320	SF	8	58,560
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 21'-6" wide strip	1,364	SF	8	10,912
30	New Work				
31	New concrete topping to match existing	1,220	SF	15	18,300

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : BROADWAY JCT/EAST NY - C TRAIN

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [C - TRAIN] =	610	LF		
5	LENGTH OF THE PLATFORM EDGE [C - TRAIN] =	610	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,220	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	10	CARS		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,220	LF	7	8,540
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,100	SF	12	73,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	123	CY	2,500	307,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,222	EA	25	30,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,222	EA	25	30,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,220	LF	95	115,900
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,220	LF	15	18,300
26	Remove existing platform tiles	1,220	LF	12	14,640
27	Sawcut existing topping concrete at perimeter of removal area	1,220	LF	5	6,100
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,320	SF	8	58,560
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 21'-6" wide strip	1,364	SF	8	10,912
30	New Work				
31	New concrete topping to match existing	1,220	SF	15	18,300

46	Concrete cove to match existing	41	LF	20	820
47	Interior Wall Finish - Paint	680	SF	5	3,400
48	Allow for Misc. floor & ceiling finishes	189	SF	15	2,835
49	Allow for 4" thick concrete pads for equipment	47	SF	20	945
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,205	SF	750	1,653,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	225,885	225,885
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : BROADWAY JCT/EAST NY - C TRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,220	LF	60	73,200
	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Rooms from EDR [Conduit & Cable]	400	LF	60	24,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	450	LF	60	27,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

24-Jun-19

STATION : VAN SICLEN AVE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	598	LF		
5	LENGTH OF THE PLATFORM EDGE =	598	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,196	LF

STATION : AQUEDUCT RACE TRACK

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE =	689	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	**689**	**LF**		
6	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
7					
8	**AUTOMATIC PLATFORM GATES [APG's]**				
9					
10	**Platform edge reconstruction**				
11	Demolition				
12	Remove existing polyethylene edge strip	689	LF	7	4,823
13	Remove 5' wide section of 3" deep structural slab to platform edge	3,445	SF	12	41,340
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	70	CY	2,500	175,000
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	691	EA	25	17,275
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	691	EA	25	17,275
18	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
19	Polyethylene edge strip	689	LF	95	65,455
20	Provide sleeves for HV & LV wires	328	EA	110	36,080
21					
22	**Platform edge finishes**				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	689	LF	15	10,335
25	Remove existing platform tiles	689	LF	12	8,268
26	Sawcut existing topping concrete at perimeter of removal area	689	LF	5	3,445
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	4,134	SF	8	33,072
28	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 43'-8" wide	3,014	SF	8	24,109
29	New Work				
30	New concrete topping to match existing	689	SF	15	10,335
31	New concrete topping at ADA boarding area to match existing	3,014	SF	15	45,204

24-Jun-19

STATION : HOWARD BEACH AIRTRAIN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	692	LF		
5	LENGTH OF THE PLATFORM EDGE =	692	LF

STATION : BEACH 98TH ST

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE =	839	LF		
5	LENGTH OF THE PLATFORM EDGE =	839	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,678**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,678	LF	7	11,746
14	Remove 5' wide section of 3" deep structural slab to platform edge	8,390	SF	12	100,680
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	169	CY	2,500	422,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,680	EA	25	42,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,680	EA	25	42,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,678	LF	95	159,410
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,678	LF	15	25,170
26	Remove existing platform tiles	1,678	LF	12	20,136
27	Sawcut existing topping concrete at perimeter of removal area	1,678	LF	5	8,390
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	10,068	SF	8	80,544
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 10'-10" wide	387	SF	8	3,098
30	New Work				
31	New concrete topping to match existing	1,678	SF	15	25,170
32	New concrete topping at ADA boarding area to match existing	387	SF	15	5,808

STATION : ROCKAWAY PARK BEACH 116TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	731	LF		
5	LENGTH OF THE PLATFORM EDGE =	731	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,462**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**

24-Jun-19

STATION : BEACH 60TH ST STATION AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	690	LF		
5	LENGTH OF THE PLATFORM EDGE =	690	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,380**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,380	LF	7	9,660
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,900	SF	12	82,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	139	CY	2,500	347,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,382	EA	25	34,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,382	EA	25	34,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,380	LF	95	131,100
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,380	LF	15	20,700
26	Remove existing platform tiles	1,380	LF	12	16,560
27	Sawcut existing topping concrete at perimeter of removal area	1,380	LF	5	6,900
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,280	SF	8	66,240
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 10'-8" wide	374	SF	8	2,989
30	New Work				
31	New concrete topping to match existing	1,380	SF	15	20,700

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for A/C - Line Stations

24-Jun-19

STATION : BEACH 36TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE [SOUTH BOUND] =	677	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	677	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,354**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,354	LF	7	9,478
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,770	SF	12	81,240
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	136	CY	2,500	340,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,356	EA	25	33,900
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,356	EA	25	33,900
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,354	LF	95	128,630
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,354	LF	15	20,310
26	Remove existing platform tiles	1,354	LF	12	16,248
27	Sawcut existing topping concrete at perimeter of removal area	1,354	LF	5	6,770
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,124	SF	8	64,992
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 10'-10" wide	387	SF	8	3,098
30	New Work				
31	New concrete topping to match existing	1,354	SF	15	20,310

0.0 Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 32 newly evaluated stations, 12 have been found to be not suitable for the installation of PSDs.

> *[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]*

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32", it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32"
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit. There are structural anomalies affecting the ability of platform edges to support PSD loads occurring at the three stations on the 63rd Street line as well as at three stations on the 6th Avenue line. These stations required a further structural analysis that can be found in the station specific reports.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the E line service and an overlapping service on the B Division will remain incompatible even after 2032. The E is a ten-car train, whereas the M line is an eight-car train. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The M train cannot be extended to a ten-car length because all the station stops in Brooklyn feature station platforms of an eight-car length. Therefore, 16 of the 32 stations are infeasible due to this incompatibility. Please see the diagrams in Figure 1 below.

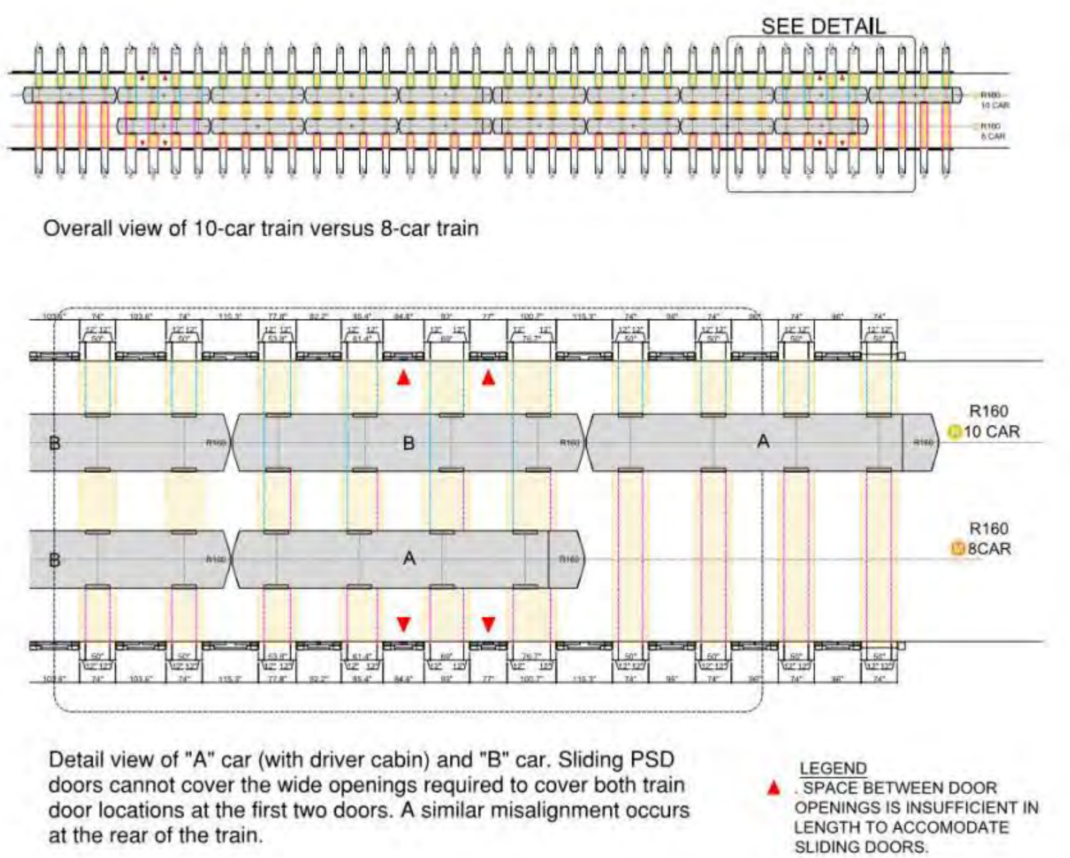

***Figure 1** – Ten-car vs. eight-car train Comparison of door geometry*

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the wall and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for removal of garbage at the stations on the 'E' Line. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the off-loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in the damage from these carts which can be observed along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 37% of the 'E' Line stations. Total implementation cost would be $390.0M for APGs and $504.0M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 12 feasible stations, the aggregate annual maintenance cost would be $11.2M.

Summary Table

'E' Line Summary of Feasibility (37% feasible; 12/32)

MR	Station Name	Station Type	Platform Type	Feasible Yes/No	Issues/ Reason for Failure	Cost APGs	Cost PSDs
162	50th Street	SUB	Side	Yes		$33.7M	$43.3M
163	42nd Street Port Authority Bus	SUB	Center/Island	No	ADA clearance		
164	34th Street Penn Station	SUB	Side	Yes		$32.5M	$40.7M

					TOTAL	$390.0M	$504.0M

1.0 Station Assessments

1.01 – MR 162 | 50th Street Station

Summary: *50th Street Station is feasible for both APGs and PSDs. In this two-level station, please note that only the lower platforms were evaluated for this study since the E train stops at that level. There are two ceiling mounted signals located at the queens-bound lower platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate. .*

Description

50th Street Station is a below-grade station with two levels of side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. This report only covers the lower level platforms as the upper level platforms service the "C" line which will be examined in an upcoming report. The platform columns are spaced 15'-0" on center, and column faces typically measure 2'-10" from the southbound platform edge and 3'-4" from the northbound platform edge. The southbound platform width varies from 11'-6" to 15'-4" throughout. The northbound platform width varies from 11'-8 to 15'-6". On the northbound platform there are two ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage. The signals located above the platform edge would need to be reoriented from a horizontal orientation to a vertical orientation in the implementation of full height PSDs**.**

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The E-line utilizes only the lower platform; therefore costs generated in this report will only include one equipment room. However, for planning purposes, the location of both equipment rooms have been examined to assure feasibility for the station as a whole. The equipment room for the upper C-line platform could be located at closed control area N053 (not shown; will be detailed in upcoming C-line report) and the equipment room for the lower E-line platform could be located at the far south end of the southbound platform. (**Figure 1 & Figure 2).** The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.5. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Table of Contents

50th Street Station

***Figure 3** – Typical view – lower platform*
50th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:
This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	50th Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	96.0
Apparent Power (kVA)	120.0
Station Peak Demand Load, Max Current, (A)	333.3
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	674
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	526
Is Electrical Service Adequate?	**Yes**
Notes	Analysis is based on 1 line diagram. The station has (2) separate meters with combined meter reading. (Services indicate 1200 A fuses at service switches)

***Table 1**- Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.7M to install APGs and $43.2M to install PSDs (See Appendix E)

1.02 – MR 163 | 42nd Street Port Authority Station

Summary: *42nd Street Port Authority Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at the ramp locations on both platform. Wheelchair paths at the ramp locations would be constricted to less than 32".*

Description

42nd Street Port Authority Station is a below-grade station with two straight center/island platforms. The platform structure are cast-in-place concrete. The width of the southbound platform is approximately 35'-0" throughout tapering down to 16'-3" towards the northern end. The width of the northbound platform is approximately 29'-0" throughout tapering down to 24'-0" towards the southern end. There is one ramp along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-4" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

Figure 1 – *Non-Compliant ADA condition at ramp*
42nd Street Port Authority

1.03 – MR 164 | 34th Street Penn Station

***Summary:** 34th Street Penn Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located above the each platform edge with a vertical clearance ranging between 7' 4" and 8'0", which would require relocation to implement an APG or PSD system. Platform structural work would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is inadequate. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

34th Street Penn Station is a below-grade station with two straight side platforms and one center/island platform **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 4'-0" from the platform edge. The southbound side platform width varies from approximately 11'-8" to 12'-0" throughout. The northbound side platform width is approximately 11'-6" throughout. The center/island platform width is approximately 25'-6" throughout. On each platform there are two ceiling mounted monitors located above the platform edge, with a vertical clearance of at least 7'-4" **(see Figure 4)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted monitors located above the platform edge would need to be relocated in the implementation of full height PSDs (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the south of the mezzanine, flush to the wall across from staircase M24A (**see Figure 1, Figure 2, and Figure 3)**. The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.4M to install APGs and $40.6M to install PSDs (See Appendix E)

***Figure 4** – Typical platform view with signal light*
34th Street Penn Station

1.04 – MR 165 | 23rd Street Station

Summary: *23rd Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at the north end of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

23rd Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound side platform width varies from approximately 11'-10" to 17'-8". The northbound side platform width is also approximately 11'-6" to 17'-8". On the north end of the southbound platform there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6" **(see Figure 3)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted monitors located above the platform edge would need to be relocated in the implementation of full height PSDs (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the south end of the southbound platform, flush to the wall (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.4M to install APGs and $42.4M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with signal light*
23rd Street Station

1.05 – MR 166 | 14th Street Station

Summary: *14th Street Station is feasible for both APGs and PSDs. Note that only the outer platform edges were evaluated for this study; the inner edges will be the subject of an upcoming report for the A-line. There are two ceiling mounted signals located on each platform which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is inadequate. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

14th Street Station is a below-grade station with two straight center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 10'-9" from the platform edge. The southbound platform width varies from approximately 21'-4" to 22'-4". The northbound platform width also varies from approximately 21'-4" to 22'-4". On both platforms there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-4". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, standard NYCT wayfinding signage, and ceiling mounted monitors. A signal light will need to be re-positioned to facilitate installation of a full-height system.

***Half Height PSDs (aka APGs)*: This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. Since the E train only impacts two of the four platform edges, the cost estimate only includes one equipment room. The equipment rooms could be located at the south of the mezzanine, adjacent to staircase P18 (**see Figure 1, Figure 2 & Figure 3**). The proposed room dimensions are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 1.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

14th Street Station

Platform obstructions within 5’ of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:
This station has inadequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	14th Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	339.2
Apparent Power (kVA)	424.0
Station Peak Demand Load, Max Current, (A)	1177.8
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	1518
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**NO**
Notes	Analysis is based on 1 line diagram. The station has (2) separate meters with combined meter reading. (Service was upgraded from 800 A to 1200A)

Table 1: *Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.6M to install APGs and $43.0M to install PSDs (See Appendix E)

Figure 4 *– Typical platform view with signal light*
14th Street Station

1.06 – MR 167 | West 4th Street Station

Summary: *West 4th Street Station is feasible for both APGs and PSDs. Note that only the upper 8th Avenue platforms were evaluated for this report; the lower 6th Avenue platforms will be evaluated in an upcoming report. There are two ceiling mounted signals located at the northbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B).* Existing power is inadequate. *We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

West 4th Street Station is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. This report only covers the upper level platform as the upper level platform services the "E" line. The lower level will be reported on in a subsequent report. The platform columns are spaced 15'-0" on center, and column faces typically measure 3'-4" from platform edge. The northbound platform width measures approximately 25'-6" throughout. The southbound platform width measures approximately 27-2" throughout. On the southbound platform there are two ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground the **(see Figure 4)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The signals located above the platform edge would need to be reoriented from a horizontal orientation to a vertical orientation in the implementation of full height PSDs **(see figure 4).**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at the upper level of this station, 2 full size equipment rooms would be required. Since the E train only impacts two of the four platform edges, the cost estimate only includes one equipment room. The equipment rooms could be located in the mezzanine (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.625. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Total Load (Station Peak + PSD), (A)	1354
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	Analysis is based on 1 line diagram. The station has (2) separate meters with combined meter reading. (Services indicate 1200 A fuses at service switches)

Table 1*- Power Capacity Analysis*

Historic Restrictions:
West 4th Street Station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not

based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.8M to install APGs and $41.4 to install PSDs (See Appendix E)

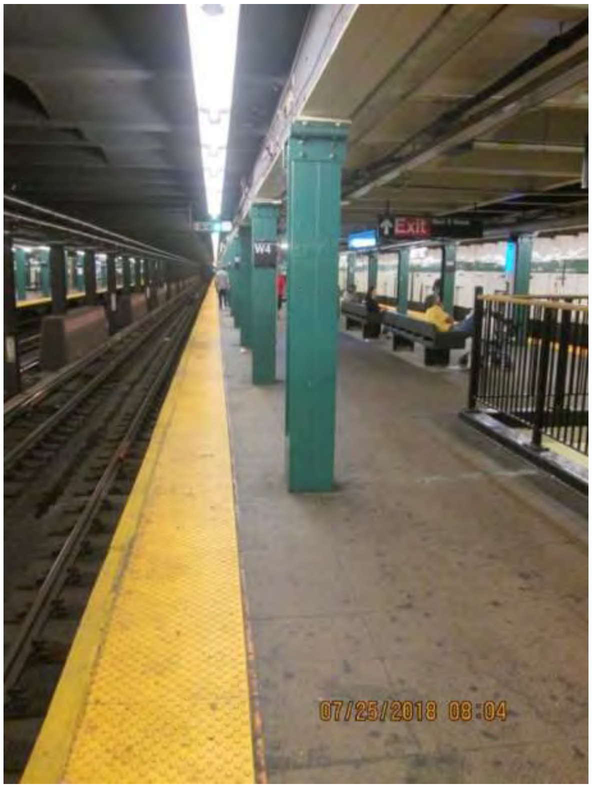

***Figure 4** – Typical platform view with signal light*
West 4th Street Station

1.07 – MR 168 | Spring Street Station

Summary: *Spring Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Spring Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound side platform width varies from approximately 11'-8" to 17'-8". The northbound side platform width varies from 11'-8" to 17'-0". On both platforms there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-5" **(see Figure 3)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs **(see Figure 3).**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the north end of the north platform, flush to the wall adjacent to staircase P14 (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.25. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Figure 3 *– Typical platform view with signal light*
Spring Street Station

1.08 – MR 169 | Canal Street Station

Summary: *Canal Street Station is feasible for both APGs and PSDs. There are three ceiling mounted signals located on each platform which would require relocation to implement a full height PSD system. Platform structural work would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Canal Street Station is a below-grade station with two straight center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 10'-6" from the platform edge. The southbound platform width varies from approximately 15'-6" to 22'-4". The northbound platform width varies from approximately 19''-6" to 22'-2". On both platforms there are three ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-1" **(see Figure 4)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs **(see Figure 4).**

***Half Height PSDs (aka APGs)*: This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the center of the mezzanine, flush to the adjacent to Transit Police Offices (**see Figure 1, Figure 2 & Figure 3**). The proposed room dimensions are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required only for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.25. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.4M to install APGs and $44.2M to install PSDs (See Appendix E)

***Figure 4** – Typical platform view with signal light*
Canal Street Station

1.09 – MR 171 | World Trade Center Station

Summary: *World Trade Center Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the platform edges which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

World Trade Center Station is a below-grade station with one center/island platforms **(see Figure 1)**. The platform structure is cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 4'-0" from the platform edge. The platform width ranges from approximately 16'-2" to 34'-6". On the platform there are two ceiling mounted signals located above the platform edge, one measuring at 7'-0" above the ground the second measuring 7'-4" above the ground. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the northern mezzanine between staircase P11 & P12 (**see Figure 1, Figure 2**). The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 1.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Figure 3 ***–*** *Typical platform view*
World Trade Center Station

Table of Contents

1.10 MR-258 | Briarwood Station

***Summary:** Briarwood Station (MR-258) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 23" (see figure 1). This condition occurs at all stairs on both platforms.*

Description

Briarwood Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 11'-4". There are four staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns divide the path between the stairs and the platform edge. Column spacing along the length of the platform is approximately 15'-0" on center and column faces are typically 3'-2" to the edge of the platform. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-2"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 23" would not allow for ADA compliant wheelchair movement nor regular passenger movement.

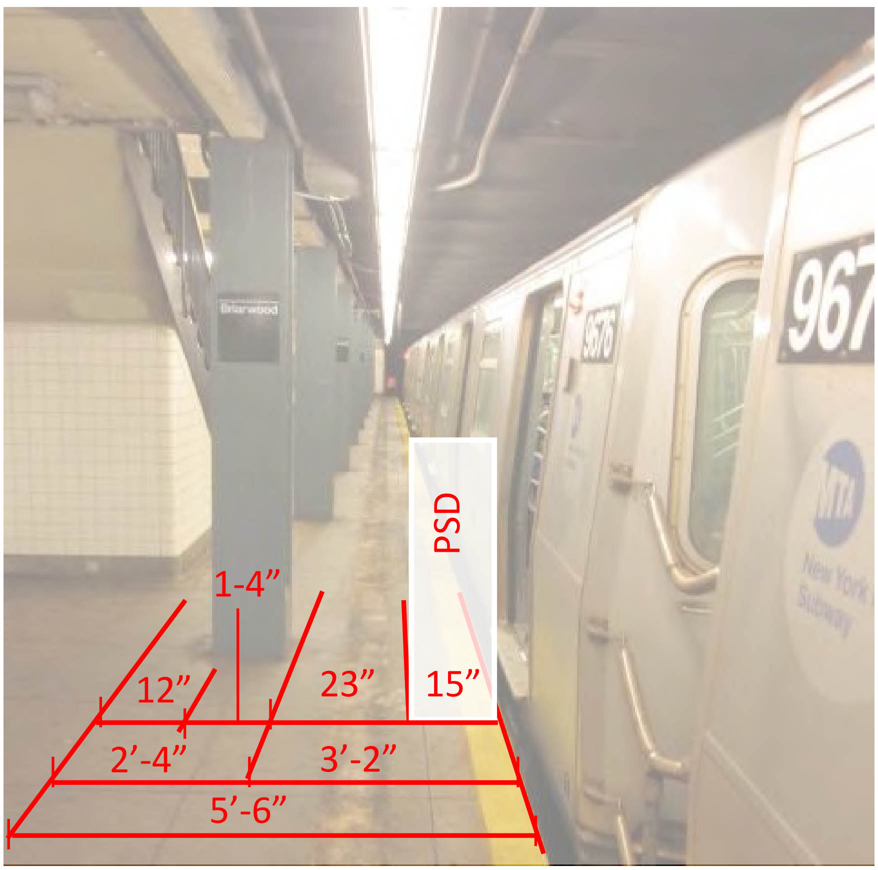

Figure 1 – Non-compliant ADA condition at stairs (typical)- Briarwood Station

1.11 MR-259 | Kew Gardens-Union Turnpike Station

Summary: *Kew Gardens-Union Turnpike Station (MR-259) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met on one side of the platform (see figure 1). The remaining width would be 24".*

Description

Kew Gardens-Union Turnpike Station is a below-grade station consisting of two mildly curved center/island platforms. The cast-in-place concrete platforms are accessed via two mezzanines. There are six stairs and an elevator located on each platform. The platform is approximately 19'-0" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-3" to the edge of the platform. Currently, at all stairs along the length of the platform a wheel chair can move between the columns and the platform edge (3'-3"). All of the stairs are off center as shown in figure 1. Although there is adequate clear space on one side of the platform, the implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement at the other side. Similarly, the elevators are shifted towards one side of the platform not allowing for 32" clearance (at one platform edge) for ADA compliant wheelchair movement. Both platform edges need to comply in order for the station to be ADA compliant for the implementation of a platform edge barrier.

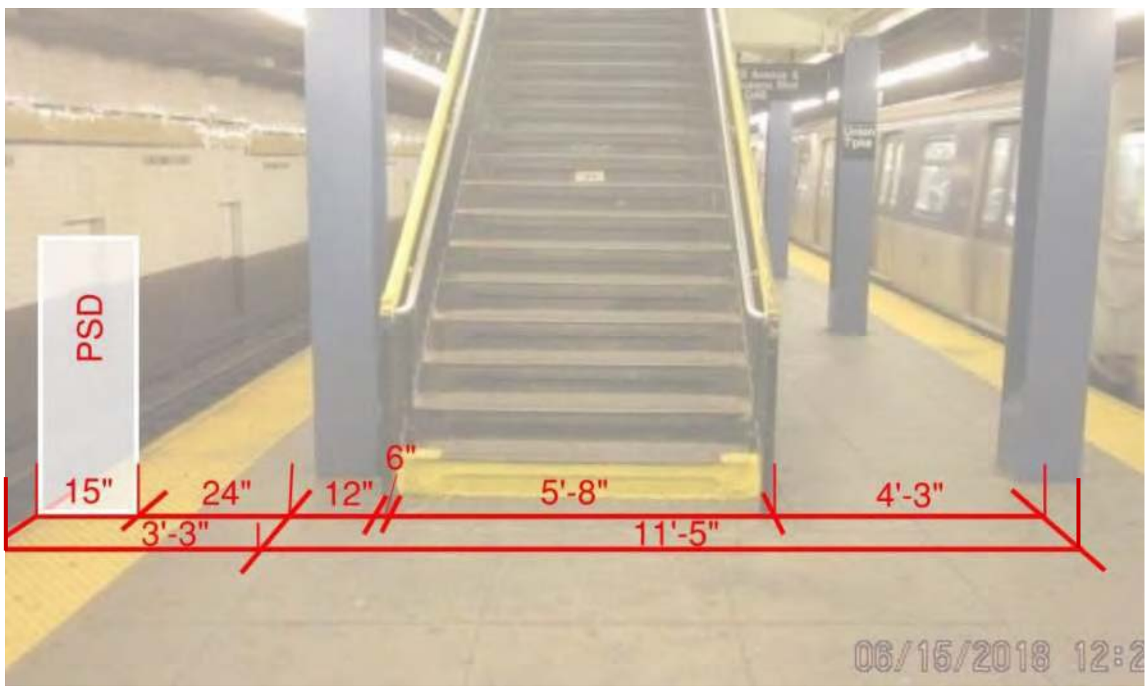

Figure 1 – Non-compliant condition on one side of the center/island platform- Kew Gardens-Union Turnpike

1.12 MR-260 | 75th Avenue Station

***Summary:** 75th Avenue Station (MR-260) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met (see figure 1).*

Description

75th Avenue Station is a below-grade station consisting of two straight side platforms. The cast-in-place concrete platforms are accessed via a large mezzanine level. There are four stairs located in various locations along the length of each platform. The platforms are approximately 11'-4" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Columns are 1'-10" away from stairs (not an ADA compliant path). Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). In the implementation of a platform edge barrier, this clearance would be reduced to 25" which is not ADA compliant.

Figure 1 – Non-compliant condition at stairs (typical) - 75th Avenue

1.13 – MR 277 | 7th Avenue Station

Summary: *7th Avenue Station is feasible for both APGs and PSDs. There are four ceiling mounted signals located at the lower platform edges which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

7th Avenue Station is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The E train utilizes the north side of both the upper and lower platform. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center. At the upper level platform, column faces are typically 5'-4" from the platform edge and the platform measures 29'-4" wide throughout save for a slight taper to 24'-6" at the eastern end of the platform. At the lower level platform column faces typically measure 2'-8" from the Queens-bound platform edge and 3'10" from the Uptown-bound platform edge, the platform width varies slightly from 21'-8" to 24'-8" save for a slight taper to 13'-0" at the western end. On the lower platform there are four ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground the **(see Figure 4)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs **(see figure 4).**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the western end of the upper level platform adjacent to staircase P9 and at the center of the lower platform (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.375. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

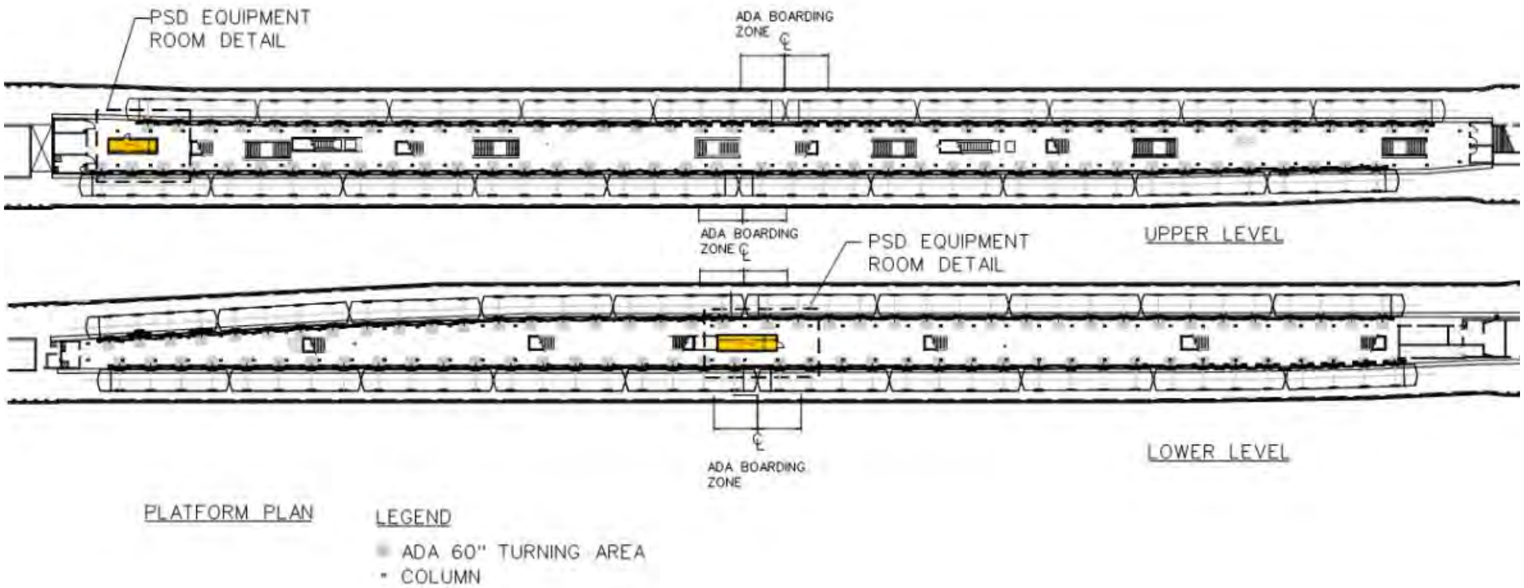

***Figure 1** – Overall Station Plan*
7th Avenue Station

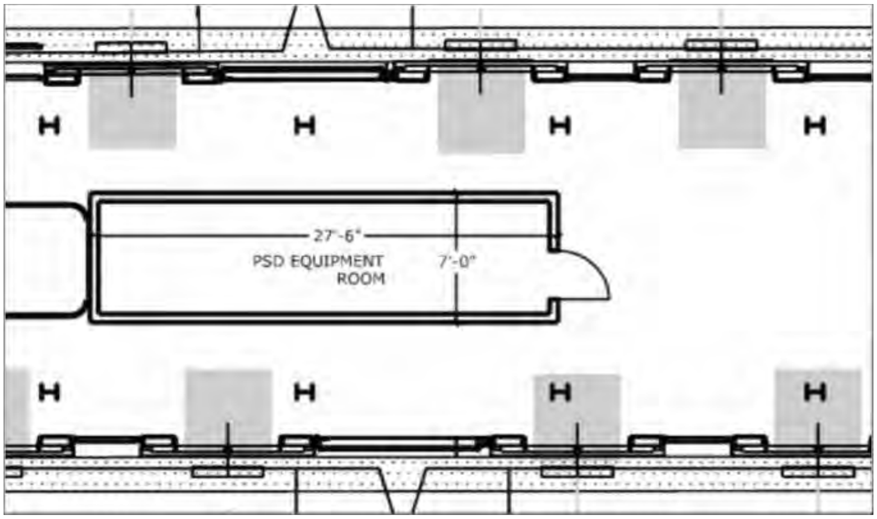

***Figure 2** – PSD Equipment Room 1 Detail*
7th Avenue Station

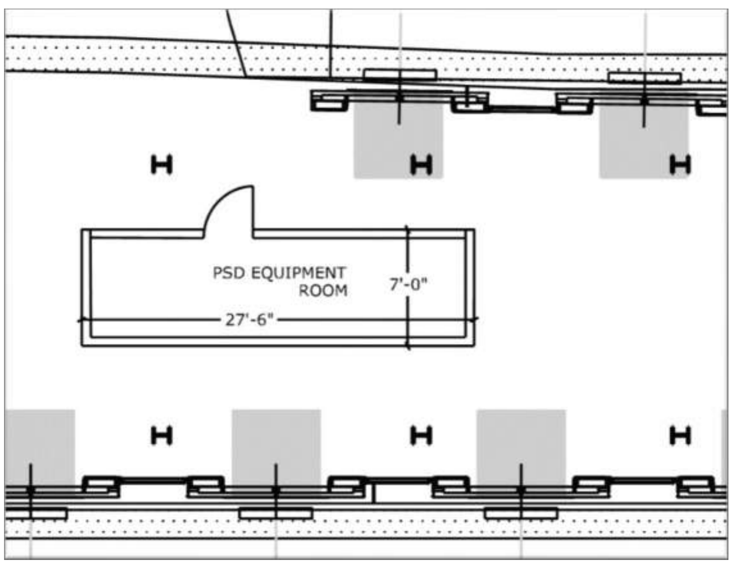

***Figure 3** – PSD Equipment Room 2 Detail*
7th Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:
This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	7th Avenue
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	78.0
Apparent Power (kVA)	97.5
Station Peak Demand Load, Max Current, (A)	270.8
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.8
Total Load (Station Peak + PSD), (A)	612
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	188
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter reading, for each Normal & Reserve service. This analysis is for **Reserve service**.

***Table 1**- Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.5M to install APGs and $42.4M to install PSDs (See Appendix E)

Figure 4 *– Typical platform view with back of signal light*
7th Avenue Station

1.14 – MR 278 | Jamaica Center – Parsons/Archer Station

Summary: *Parsons Boulevard Station is feasible for both APGs and PSDs. In this two-level station, please note that only the upper platform was evaluated for this study since the E train stops at that level. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Jamaica Center – Parsons Archer is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The platform structure is cast-in-place concrete. This report only covers the upper level platform as the lower level platform services the "J" line. The lower level will be reported on in a subsequent report. There are sparsely located columns throughout the station. These columns are either centered and measure 20'-10" apart on center, and their faces measure 11'-8" from the platform edges or the columns flank the escalators measure 25'-0" on center and their faces measure 4'-10" from the platform edge. The platform width is approximately 25'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the eastern end of the platform (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.375. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.7M to install APGs and $42.3M to install PSDs (See Appendix E)

Figure 3 *– Typical platform view*
Jamaica Center – Parsons Archer Station

1.15 – MR 279 | Sutphin Boulevard Station

Summary: *Sutphin Boulevard Station is feasible for both APGs and PSDs. In this two-level station, please note that only the upper platform was evaluated for this study since the E train stops at that level. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Sutphin Boulevard Station is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center. At the upper level platform, column faces are typically 5'-4" from the platform edge and the platform measures 29'-4" wide throughout save for a slight taper to 24'-6" at the eastern end of the platform. At the lower level platform column faces typically measure 2'-8" from the Queens-bound platform edge and 3'-10" from the Manhattan-bound platform edge. The platform width varies from 21'-8" to 24'-8" save for a slight taper to 13'-0" at the western end. On the lower platform there are four ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs**.**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 2 platform edges dedicated to the E train at this station, 1 full size equipment room would be required. The equipment room could be located at the eastern end of the upper level platform (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimensions are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.875. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.7M to install APGs and $40.6M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with back of signal light*
Sutphin Boulevard Station

1.16 – MR 280 | Jamaica Van Wyck Station

Summary: *Jamaica Van Wyck Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Jamaica Van Wyck Station is a below-grade station with one center/island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are no columns throughout the platform **(see Figure 3),** save for 6 columns toward the southern end of the platform, these columns measure 14'-4" apart on center, and their faces measure 4'-10" from the platform edges. The platform width is approximately 24'-6" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the eastern end of the platform (**see Figure 1, Figure 2)**. The proposed room dimension is 16'-6" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge should be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

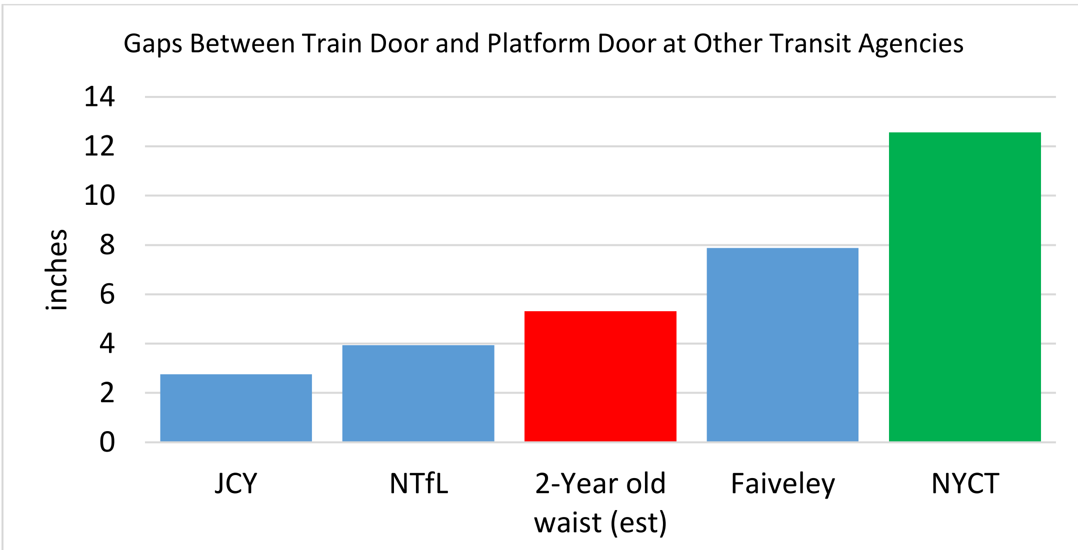

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

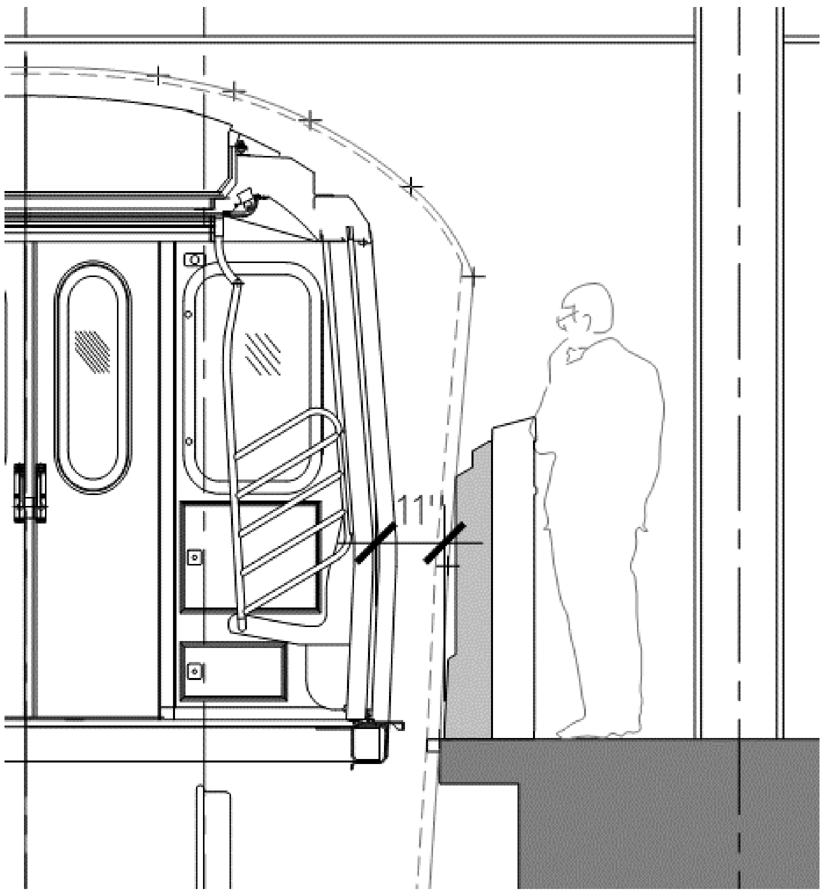

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

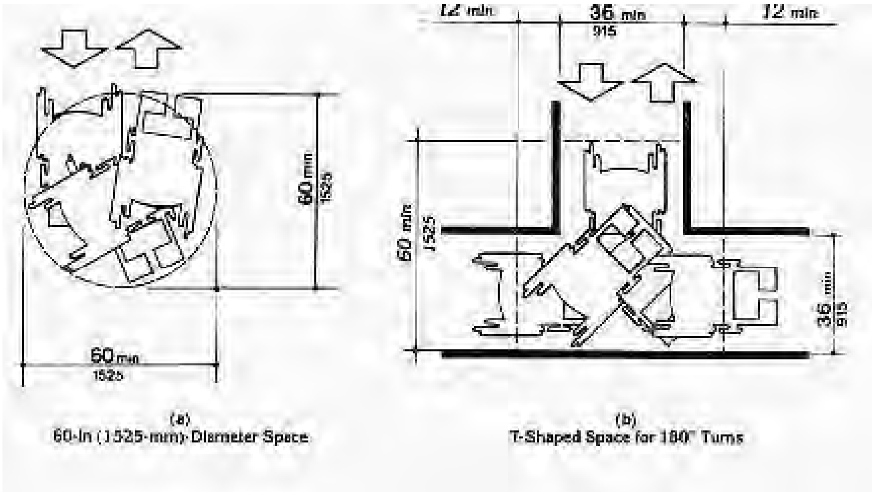
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

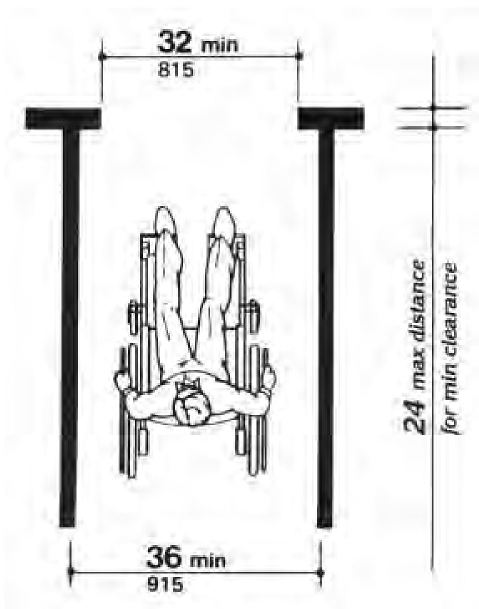


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

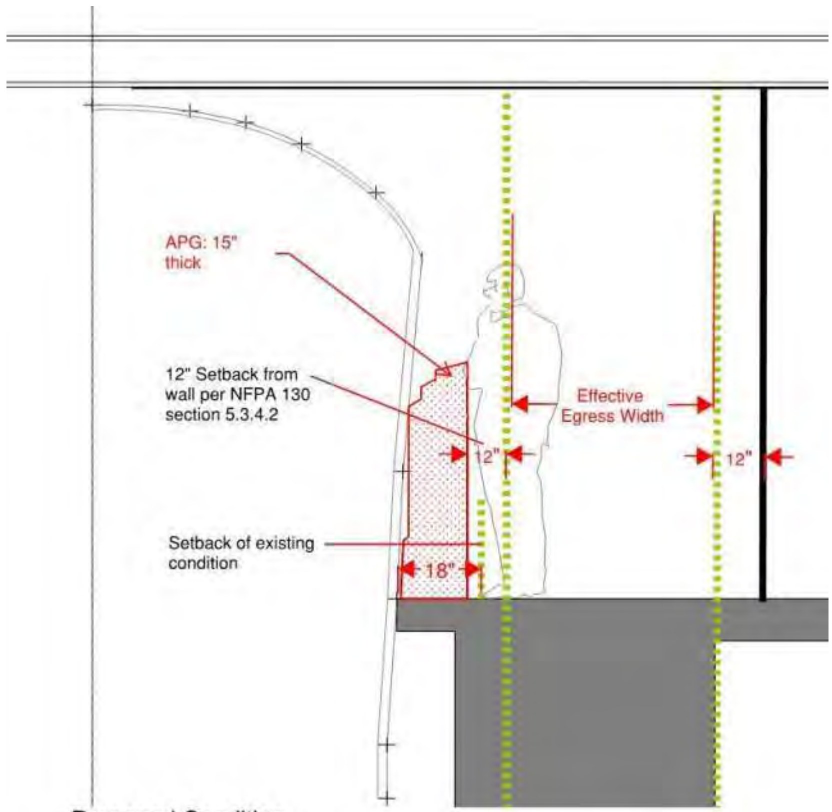
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents

Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	**CBTC**		**Dedicated loop**		**Wayside only**	
		Qty.	**subtotal**	**Qty.**	**subtotal**	**Qty.**	**subtotal**
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.

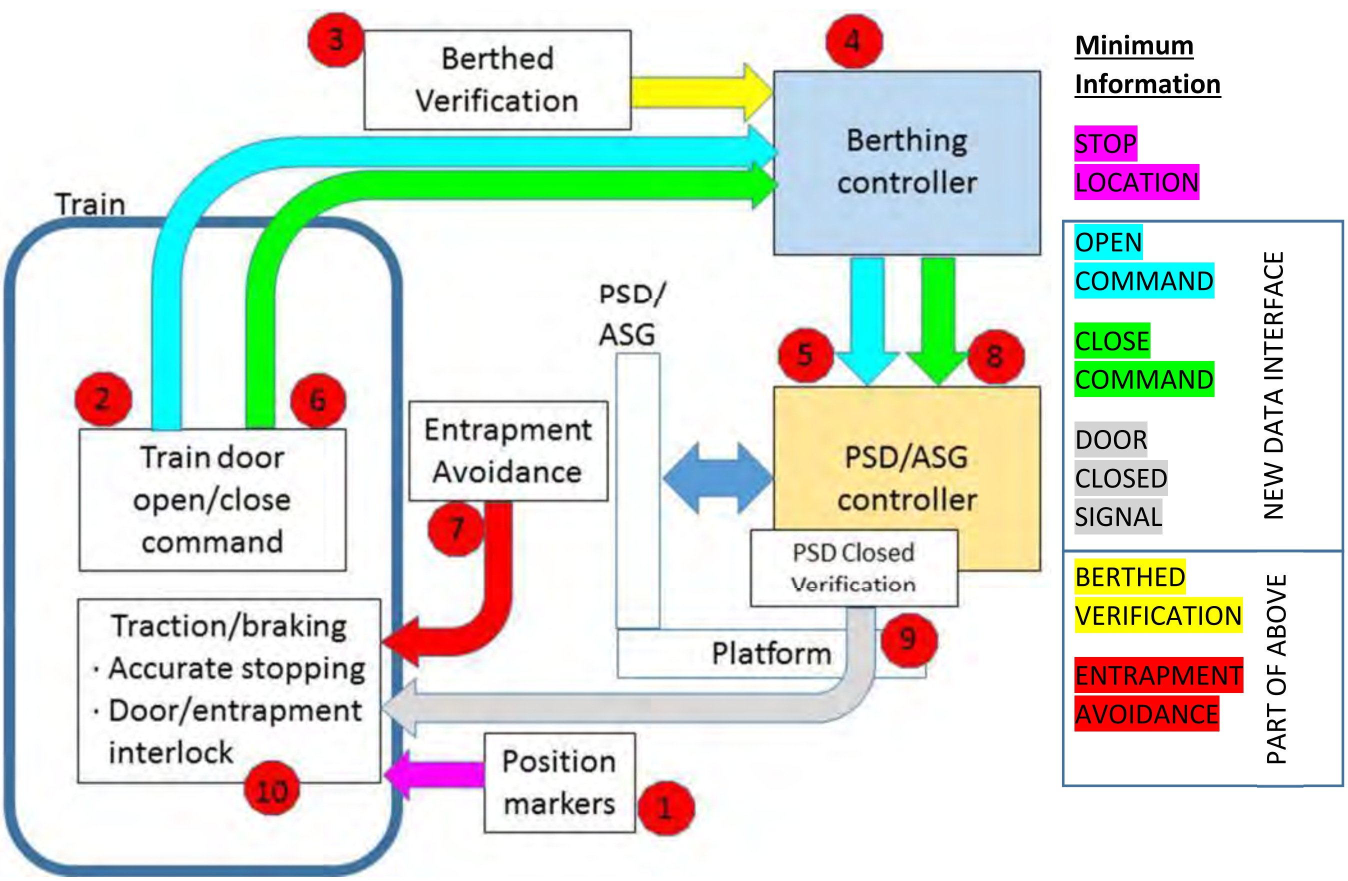

Table of Contents

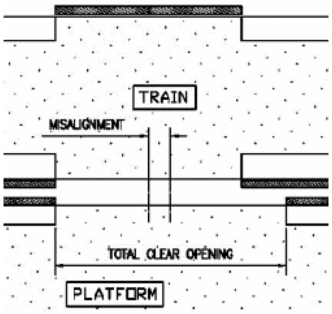
Appendix Table of Contents

Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Table of Contents

Appendix Table of Contents

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

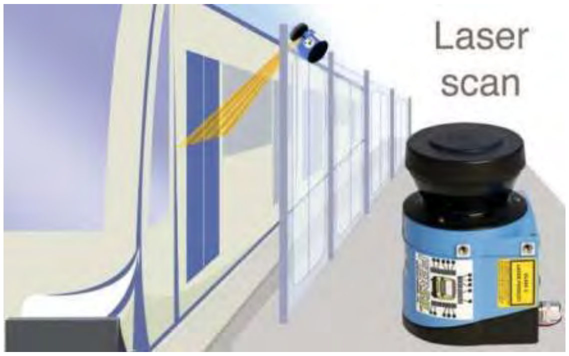
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

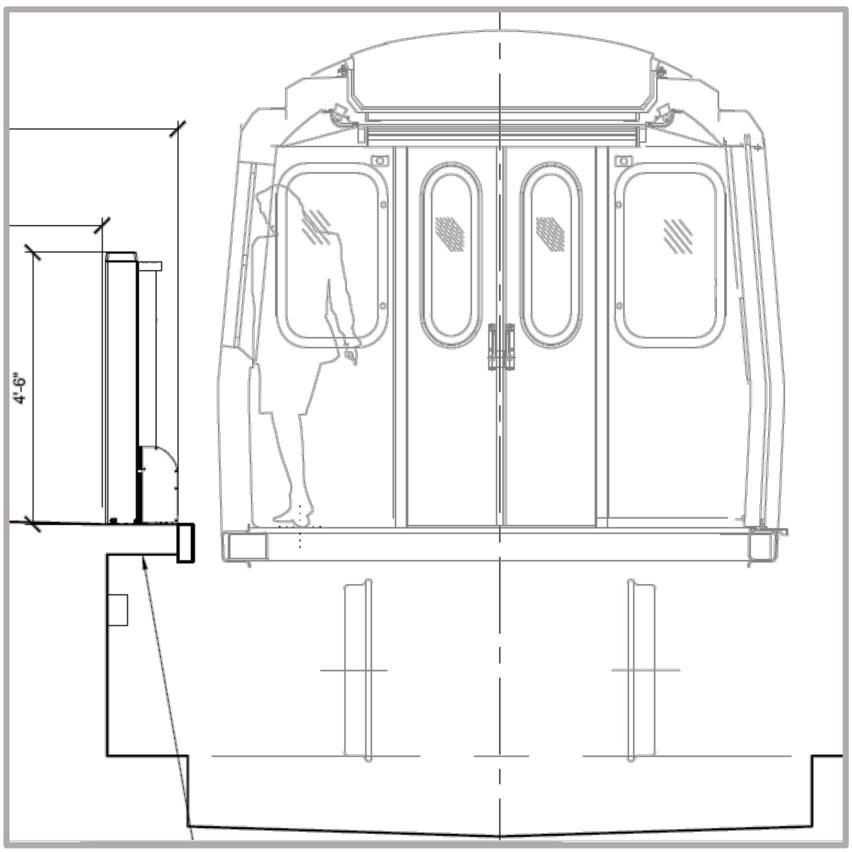


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

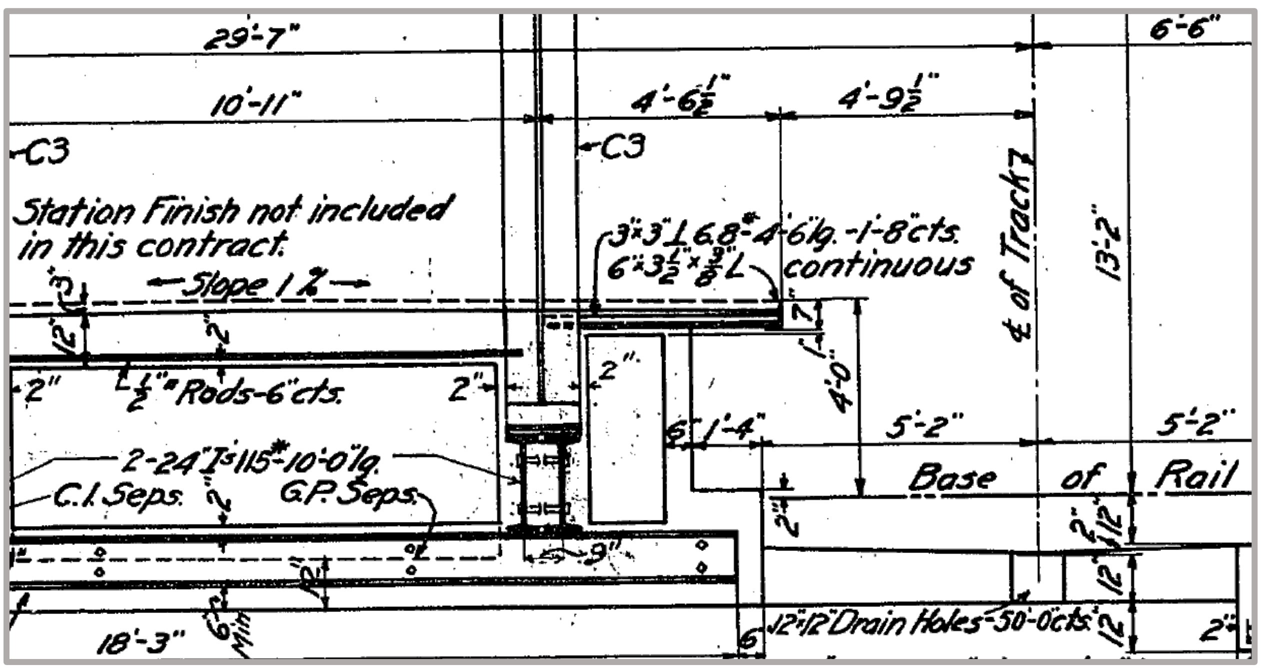

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

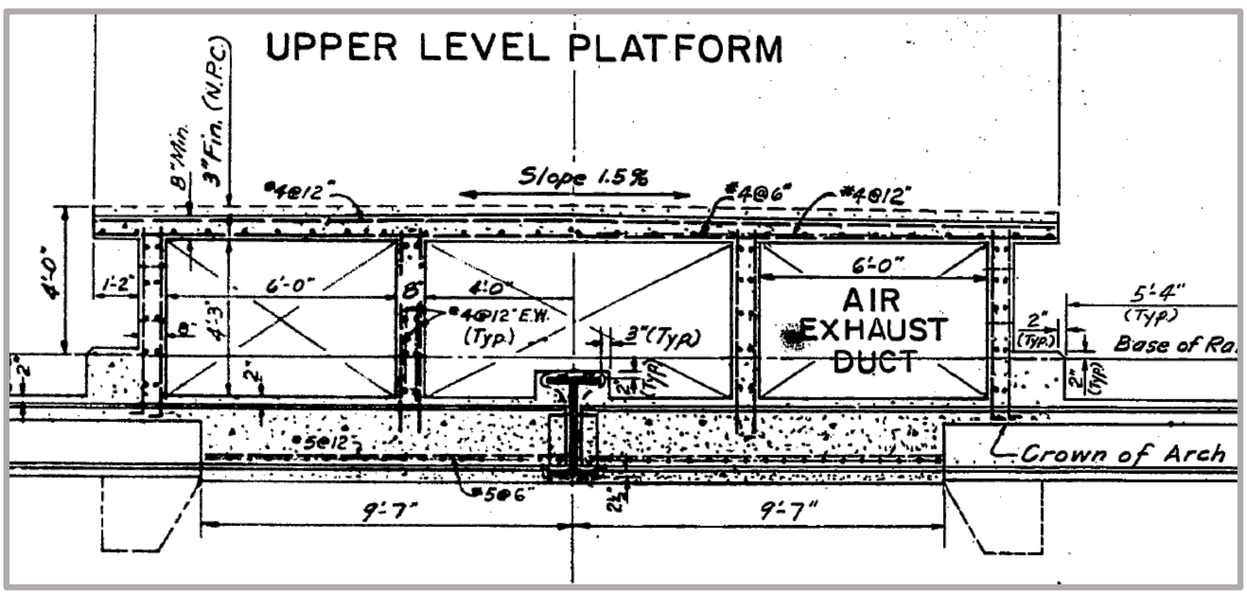

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

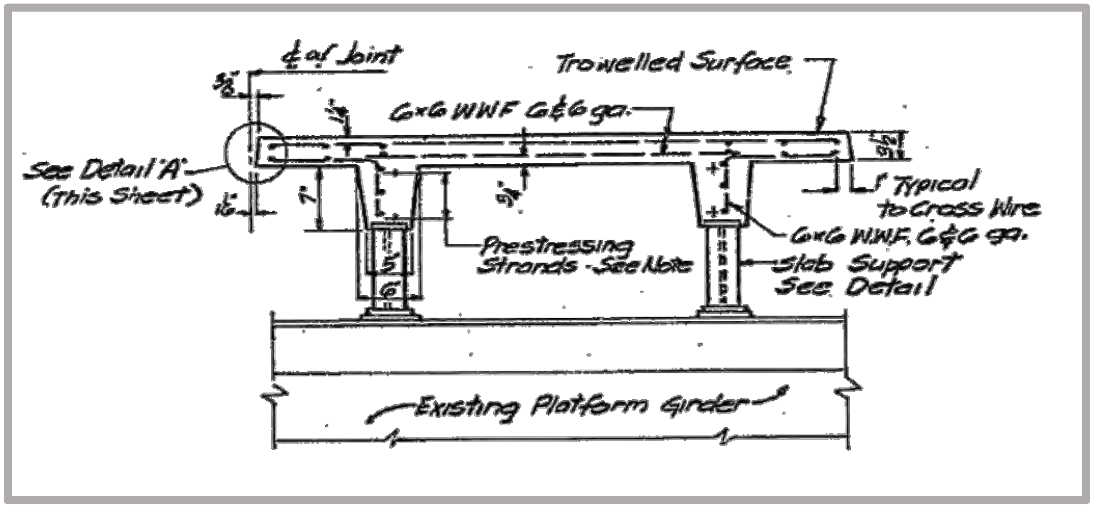

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

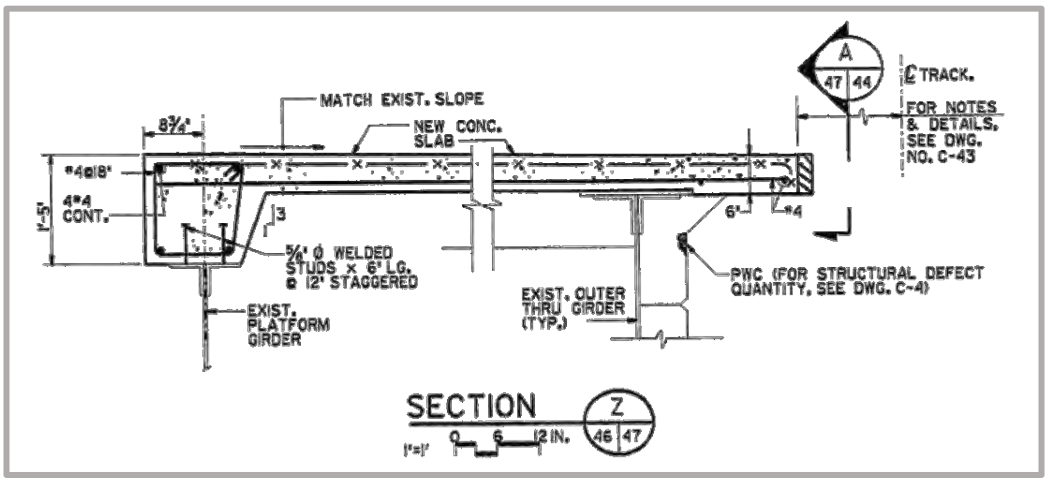

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

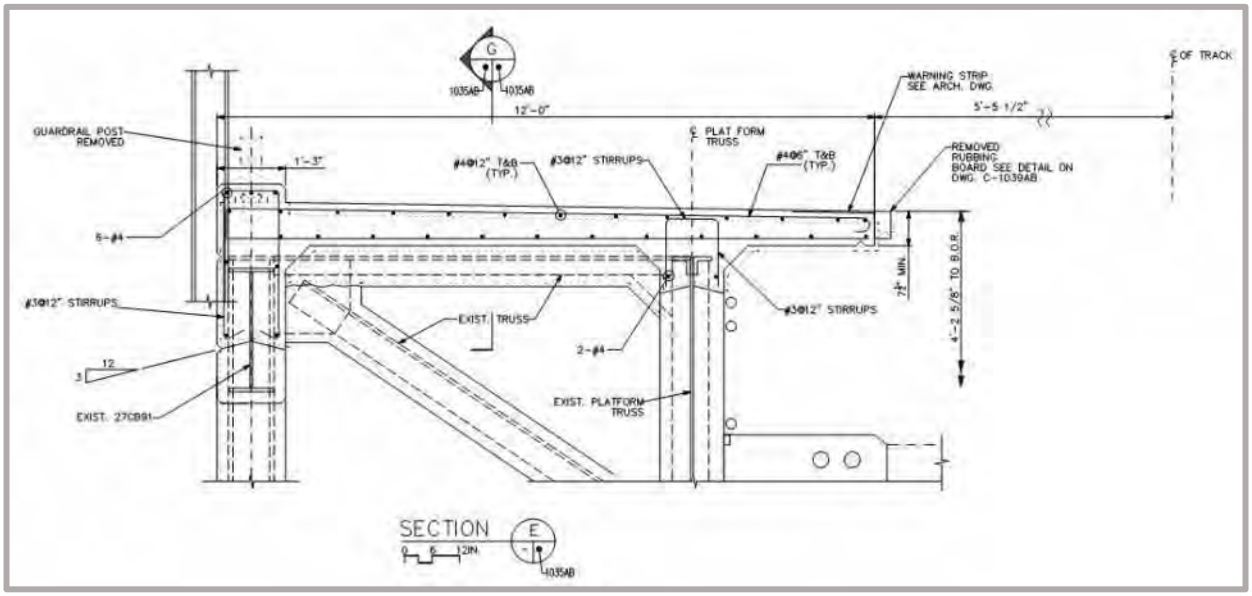

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

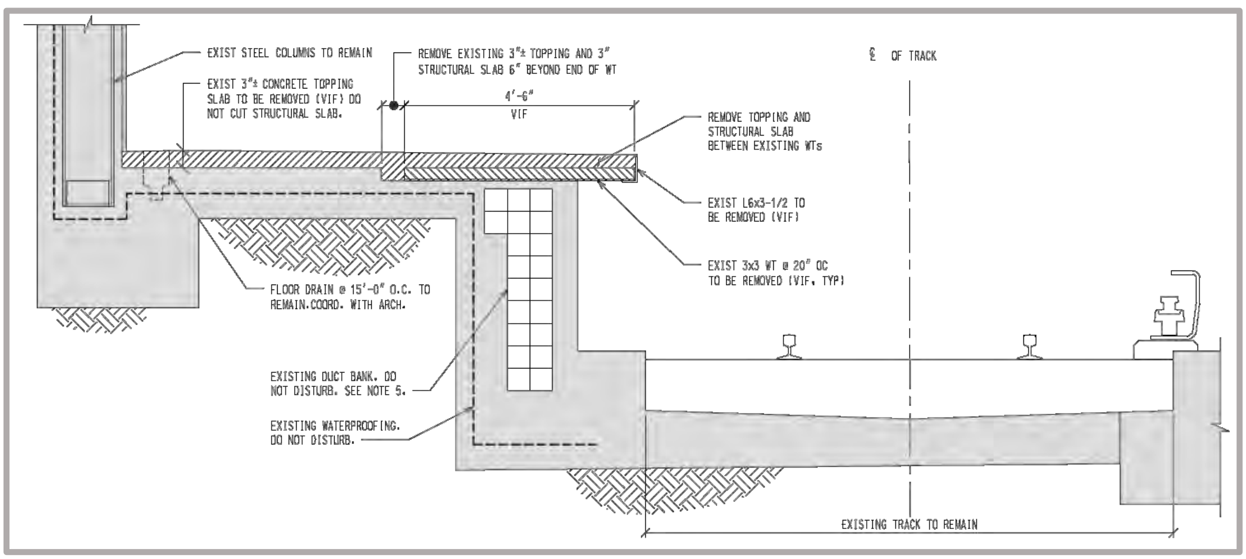

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

Table of Contents
Appendix Table of Contents

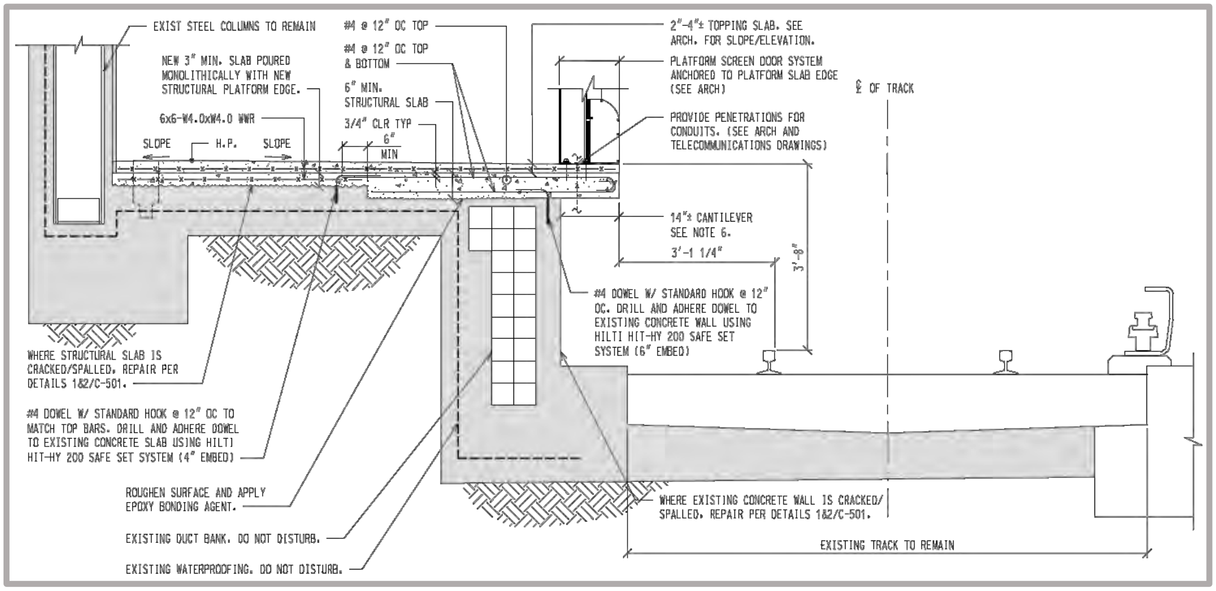

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

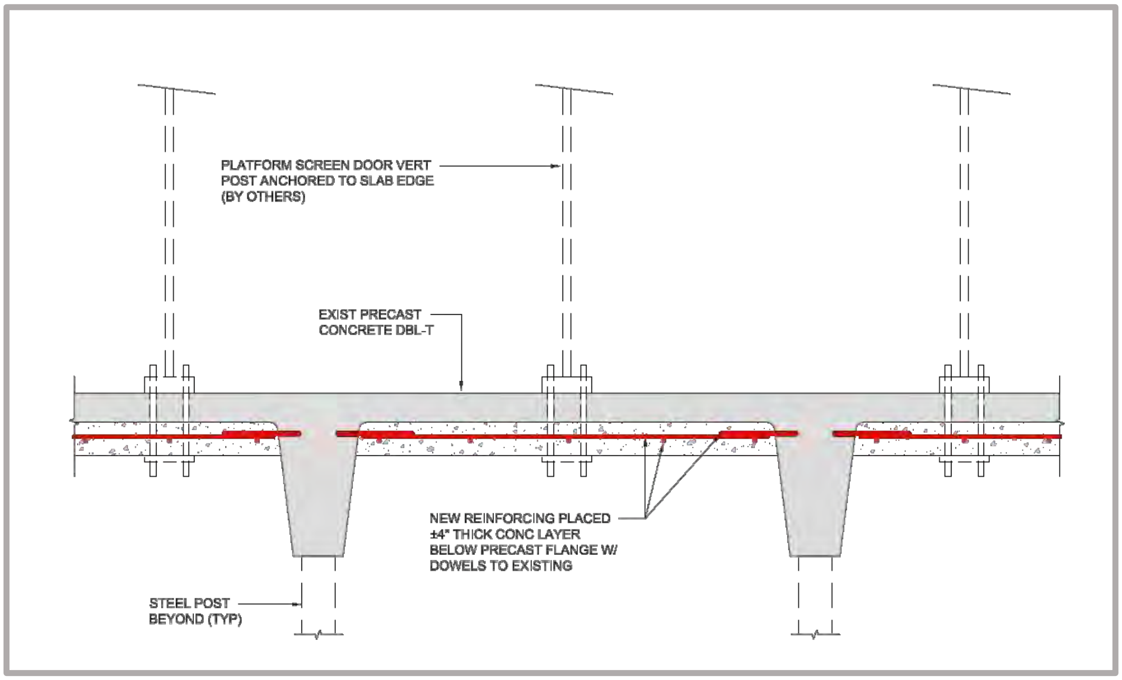

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

MTA/NYCT

September 27, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

MTA/NYCT

September 27, 2018

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 50TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE LOWER PLATFORM EDGE [SOUTH BOUND] =	660	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 50TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room - Lower Platform [6'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	61	LF	90	5,445
39	CMU Wall for equipment room	605	SF	45	27,225
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	176	SF	30	5,265
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	605	SF	40	24,200
45	Mosaic Band to match existing - Assuming 8" high	61	LF	120	7,260
46	Concrete cove to match existing	61	LF	20	1,210
47	Interior Wall Finish - Paint	605	SF	5	3,025
48	Allow for Misc. floor & ceiling finishes	176	SF	15	2,633
49	Allow for 4" thick concrete pads for equipment	44	SF	20	878
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,655	SF	750	1,991,250
61	Spare Parts - Approx. 10% of Material Cost	1	LS	246,135	246,135
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,500,000	1,500,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 50TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,320	LF	60	79,200
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	450	LF	60	27,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	500	LF	60	30,000
76	Allowance for power to cross tracks to opposite platform [Lower Level]	1	LS	15,000	15,000
77	No allowance for new lighting as if APG's are used		Note		EXCL.
78	Grounding				
79	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
80	MISC				
81	Testing and commissioning	1	EA	30,000	30,000
82	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
83					
84	**Communications**				
85	FA System				
86	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
87	CCTV coverage				
88	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
89	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
90	Berthing Technology Sensors				
91	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
92	Train Door Detection System				
93	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
94	Entrapment concerns				
95	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
96	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
97	Engineering and Testing	2,000	Hrs	160	319,860
98	Centralized monitoring/control				
99	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
100	MISC				
101	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
102	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 34TH STREET PENN STATION

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 34TH STREET PENN STATION

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room - Upper Platform [6'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	61	LF	90	5,445
39	CMU Wall for equipment room	605	SF	45	27,225
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	176	SF	30	5,265
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	605	SF	40	24,200
45	Mosaic Band to match existing - Assuming 8" high	61	LF	120	7,260
46	Concrete cove to match existing	61	LF	20	1,210
47	Interior Wall Finish - Paint	605	SF	5	3,025
48	Allow for Misc. floor & ceiling finishes	176	SF	15	2,633
49	Allow for 4" thick concrete pads for equipment	44	SF	20	878
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,655	SF	750	1,991,250
61	Spare Parts - Approx. 10% of Material Cost	1	LS	246,135	246,135
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Table of Contents

Appendix Table of Contents

STATION: 34TH STREET PENN STATION

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,320	LF	60	79,200
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	200	LF	60	12,000
76	Allowance for power to cross tracks to opposite platform; 4 Tracks between Platforms	1	LS	35,000	35,000
77	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
78	Grounding				
79	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
80	MISC				
81	Testing and commissioning	1	EA	30,000	30,000
82	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
83					
84	**Communications**				
85	FA System				
86	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
87	CCTV coverage				
88	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
89	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
90	Berthing Technology Sensors				
91	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
92	Train Door Detection System				
93	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
94	Entrapment concerns				
95	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
96	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
97	Engineering and Testing	2,000	Hrs	160	319,860
98	Centralized monitoring/control				
99	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
100	MISC

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 23RD STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 14TH STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	670	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	670	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,340**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,340	LF	7	9,380
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,700	SF	12	80,400
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,342	EA	25	33,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,342	EA	25	33,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,340	LF	95	127,300
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,340	LF	15	20,100
26	Remove existing platform tiles	1,340	LF	12	16,080
27	Sawcut existing topping concrete at perimeter of removal area	1,340	LF	5	6,700
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,040	SF	8	64,320
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,340	SF	15	20,100

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 14TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [6'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	61	LF	90	5,445
39	CMU Wall for equipment room	605	SF	45	27,225
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	176	SF	30	5,265
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	605	SF	40	24,200
45	Mosaic Band to match existing - Assuming 8" high	61	LF	120	7,260
46	Concrete cove to match existing	61	LF	20	1,210
47	Interior Wall Finish - Paint	605	SF	5	3,025
48	Allow for Misc. floor & ceiling finishes	176	SF	15	2,633
49	Allow for 4" thick concrete pads for equipment	44	SF	20	878
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,745	SF	750	2,058,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	250,185	250,185
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 14TH STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,340	LF	60	80,400
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	Allowance for power to cross tracks to opposite platform; 4 Tracks between Platforms	1	LS	35,000	35,000
77	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
78	Grounding				
79	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
80	MISC				
81	Testing and commissioning	1	EA	30,000	30,000
82	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
83					
84	**Communications**				
85	FA System				
86	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
87	CCTV coverage				
88	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
89	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
90	Berthing Technology Sensors				
91	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
92	Train Door Detection System				
93	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
94	Entrapment concerns				
95	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
96	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
97	Engineering and Testing	2,000	Hrs	160	319,860
98	Centralized monitoring/control	.			
99	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
100	MISC

STATION: SPRING STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: WORLD TRADE CENTER

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE ISLAND PLATFORM EDGE	1,320	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	1,320	LF		
6	NUMBER OF TRAIN CARS ON THIS LINE =	10	CARS		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	**Platform edge reconstruction**				
11	Demolition				
12	Remove existing polyethylene edge strip	1,320	LF	7	9,240
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
18	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
19	Polyethylene edge strip	1,320	LF	95	125,400
20	Provide sleeves for HV & LV wires	328	EA	110	36,080
21					
22	**Platform edge finishes**				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
25	Remove existing platform tiles	1,320	LF	12	15,840
26	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
29	New Work				
30	New concrete topping to match existing	1,320	SF	15	19,800
31	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 7TH AVENUE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE [SOUTH BOUND] =	658	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	658	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,315**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,315	LF	7	9,205
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,575	SF	12	78,900
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,317	EA	25	32,925
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,317	EA	25	32,925
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,315	LF	95	124,925
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,315	LF	15	19,725
26	Remove existing platform tiles	1,315	LF	12	15,780
27	Sawcut existing topping concrete at perimeter of removal area	1,315	LF	5	6,575
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,890	SF	8	63,120
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,315	SF	15	19,725

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 7TH AVENUE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room Upper Platform Level [6'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	61	LF	90	5,445
39	CMU Wall for equipment room	605	SF	45	27,225
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	176	SF	30	5,265
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	605	SF	40	24,200
45	Mosaic Band to match existing - Assuming 8" high	61	LF	120	7,260
46	Concrete cove to match existing	61	LF	20	1,210
47	Interior Wall Finish - Paint	605	SF	5	3,025
48	Allow for Misc. floor & ceiling finishes	176	SF	15	2,633
49	Allow for 4" thick concrete pads for equipment	44	SF	20	878
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,633	SF	750	1,974,375
61	Spare Parts - Approx. 10% of Material Cost	1	LS	245,123	245,123
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: 7TH AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,315	LF	60	78,900
	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Rooms from EDR [Conduit & Cable]	650	LF	60	39,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	700	LF	60	42,000
76	Allowance for power to cross tracks to opposite platform [Upper level]	1	LS	15,000	15,000
77	Allowance for power to cross tracks to opposite platform [Lower level]	1	LS	15,000	15,000
78	No allowance for new lighting as if APG's are used		Note		EXCL.
79	Grounding				
80	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
81	MISC				
82	Testing and commissioning	1	EA	30,000	30,000
83	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
84					
85	**Communications**				
86	FA System				
87	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
88	CCTV coverage				
89	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
90	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
91	Berthing Technology Sensors				
92	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
93	Train Door Detection System				
94	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
95	Entrapment concerns				
96	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
97	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
98	Engineering and Testing	2,000	Hrs	160	319,860
99	Centralized monitoring/control				
100	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000

27-Sep-18

STATION: 7TH AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
101	MISC				
102	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
103	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
104	Site Survey and Inspections	1	LS	100,000	100,000
105	Allowance for FAT (Factory Acceptance Testing) and SAT (Site Acceptance Testing)	1	LS	150,000	150,000
106	Furnish Test Equipment allowance	1	LS	500,000	500,000
107	As Built, Shop Drwgs, Permits and approvals	1	LS	50,000	50,000
108					
109	Training				
110	Allowance for training NYCT Staff - Nominal Allowance [Assuming majority of training is catered for in the Pilot Project]	1	LS	150,000	150,000
111					
112	Out of hours Work				
113	Allow loss of production to work at night say 50%	1	LS	3,979,537	3,979,537
115	TOTAL PSD WORK:				$ 17,244,660

117					
118	ADD ALTERNATIVE				
119					
120	OPTION FOR PLATFORM SCREEN DOORS [PSDS]				
121					
122	ADD				
123	Automatic bi-parting doors (10 Cars x 4 Doors = 40 No. per platform)	80	EA	25,000	2,000,000
124	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	15,000	1,170,000
125	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	30,000	60,000
126	Platform End Gates (PEGs)	4	EA	18,000	72,000
127	Fixed Panels including framing and support; Assuming 8'-0" high	5,654	SF	750	4,240,365
128	Spare Parts - Approx. 10% of Material Cost	1	LS	452,542	452,542
129	Structual framing / bracing				
130	HSS4x4x1/2 hanger	5	TONS	17,500	87,210
131	L6x6x1/2 continuous angle	10	TONS	17,500	169,372
132	Drilling and bolting - 4 bolts at each connection	408	EA	216	88,128
133	Extra for Overhead Structure at locations not covered by station canopy; Approx. 150' long	1	LS	350,000	350,000
134	Platform Edge Repair				
135	Remove concrete platform edge	-	LF	27	-
136	Platform edge repair	-	LF	109	-
137	Drilling and cast in place treaded bar for receiving base plates for PSD framing; #4 per base plate	-	EA	10	-
138	Signal Work [Each 300' length is associated with one signal light]				
139	Disconnects	80	HRS	162	12,960
140	Remove signal cables	600	LF	40	24,000
141	Remove conduit; Assuming 1”	600	LF	55	33,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: JAMAICA CTR PARSONS / ARCHER

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER ISLAND PLATFORM EDGE =	1,326	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,326**	**LF**		
6	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
7					
8	**AUTOMATIC PLATFORM GATES [APG's]**				
9					
10	**Platform edge reconstruction**				
11	Demolition				
12	Remove existing polyethylene edge strip	1,326	LF	7	9,282
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,630	SF	12	79,560
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	134	CY	2,500	335,000
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,328	EA	25	33,200
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,328	EA	25	33,200
18	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
19	Polyethylene edge strip	1,326	LF	95	125,970
20	Provide sleeves for HV & LV wires	328	EA	110	36,080
21					
22	**Platform edge finishes**				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,326	LF	15	19,890
25	Remove existing platform tiles	1,326	LF	12	15,912
26	Sawcut existing topping concrete at perimeter of removal area	1,326	LF	5	6,630
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,956	SF	8	63,648
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
29	New Work				
30	New concrete topping to match existing	1,326	SF	15	19,890
31	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920

Tier 2-3 Report on Feasibility of Platform Edge Barriers for E-Line Stations

27-Sep-18

STATION: SUTPHIN BLVD ARCHER AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER ISLAND PLATFORM EDGE =	1,230	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
6	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
7					
8	**AUTOMATIC PLATFORM GATES [APG's]**				
9					
10	**Platform edge reconstruction**				
11	Demolition				
12	Remove existing polyethylene edge strip	1,230	LF	7	8,610
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
18	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
19	Polyethylene edge strip	1,230	LF	95	116,850
20	Provide sleeves for HV & LV wires	328	EA	110	36,080
21					
22	**Platform edge finishes**				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
25	Remove existing platform tiles	1,230	LF	12	14,760
26	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
29	New Work				
30	New concrete topping to match existing	1,230	SF	15	18,450
31	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'F' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

SUBMITTAL DATE: December 19, 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 45 newly evaluated stations, 40 have been found to be not suitable for the installation of PSDs.

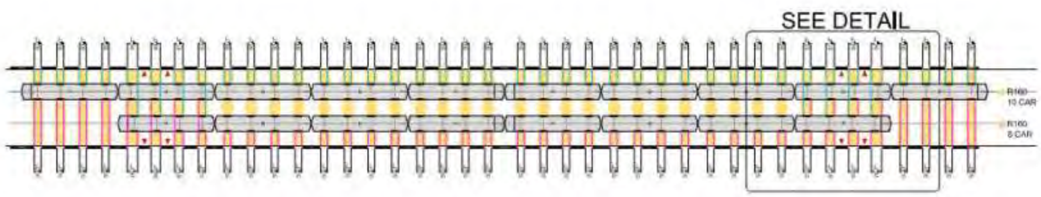
[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

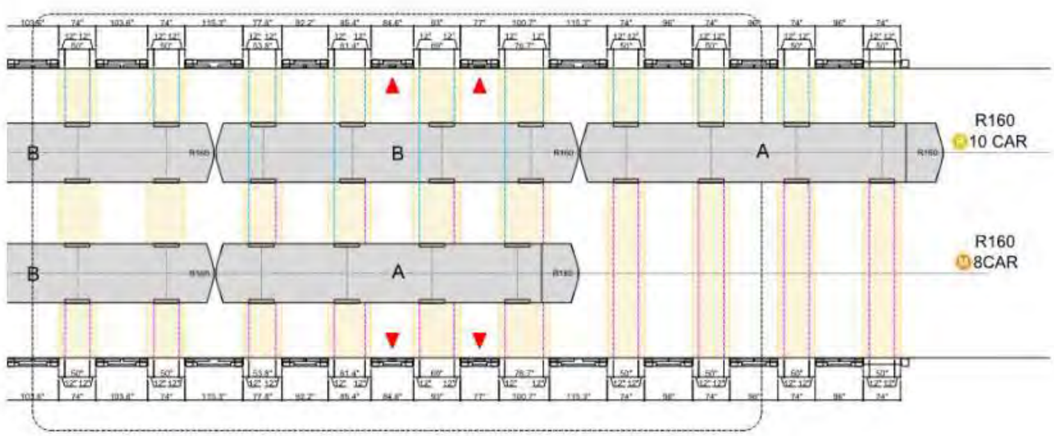
- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit. There are structural anomalies affecting the ability of platform edges to support PSD loads occurring at the three stations on the 63rd Street line as well as at three stations on the 6th Avenue line. These stations required a further structural analysis that can be found in the station specific reports.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the F-line service and an overlapping service on the B Division will remain incompatible even after 2032. The F is a ten-car train, whereas the M line is an eight-car train. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The M train cannot be extended to a ten-car length because all the station stops in Brooklyn feature station platforms of an eight-car length. Therefore, 17 of the 45 stations on the F-line are infeasible due to this incompatibility. Please see the diagrams in Figure 1 below.



Overall view of 10-car train versus 8-car train



Detail view of "A" car (with driver cabin) and "B" car. Sliding PSD doors cannot cover the wide openings required to cover both train door locations at the first two doors. A similar misalignment occurs at the rear of the train.

LEGEND
▲ SPACE BETWEEN DOOR OPENINGS IS INSUFFICIENT IN LENGTH TO ACCOMODATE SLIDING DOORS.

***Figure 1** – Ten-car vs. eight-car train*
Comparison of door geometry

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the wall and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

Please note: Electrical capacity is not considered as a factor affecting feasibility in the installation of a future APG or PSD system in this study. Inadequate electrical capacity is observed as a factor that will increase the cost of installing a future APG or PSD system.

A garbage train is used for refuse removal on the 'F' Line. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 11% of the 'F' Line stations. Total implementation cost would be $159.2M for APGs and $202.1M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be $4,655,000.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'F' Line Stations

'F' Line Summary of Feasibility (11% feasible; 5/45)

No.	Station Name	Station Type	Platform Type	Feasible Yes / No	Issues / Reason for Failure	Cost APGs	Cost PSDs

1.0 Station Assessments

1.1 MR-254 | Jamaica-179th Street Station

Summary: *Jamaica-179th Street Station (MR-254) is not feasible for both APGs and PSDs. This station is not feasible because the implementation of a platform edge barrier would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" width requirement for ADA compliant wheelchair movement would not be met at all stairs. Remaining widths would be approximately 25" (see figure 1).*

Description

Jamaica-179th Street Station is a below-grade terminus station serving the E and F trains. The station has two straight center/island platforms that are slightly tapered at the south-end of the station. Both platforms have one track dedicated to F-train service. The cast-in-place concrete platforms are accessed via the mezzanine. There are five stairs on the northbound platform & six stairs on the southbound platform. The platforms are approximately 19'-6" wide, but taper to a narrow 7'-0" at the south-end of the platform. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not permit wheelchair movement along the length of the platform.

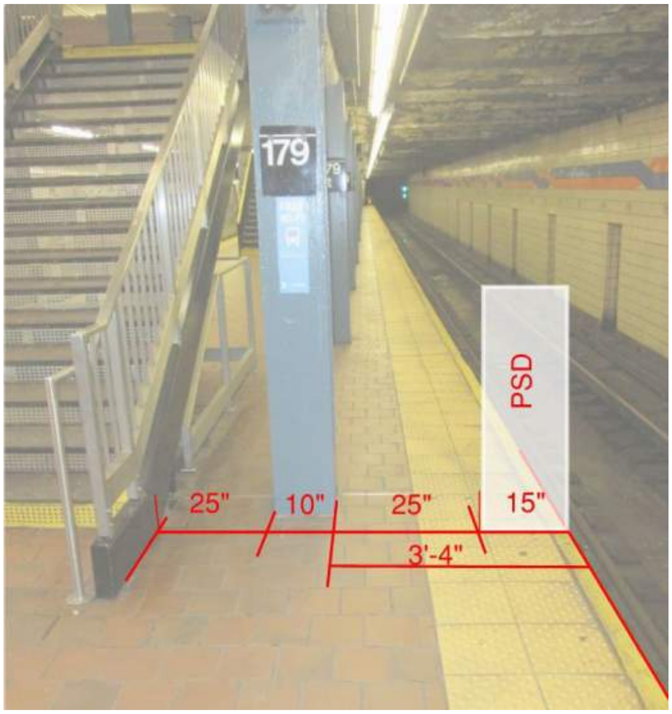

Figure 1 – Non-compliant ADA condition at stairs (typical)- Jamaica-179th Street Station

1.2 MR-255 | 169th Street Station

Summary: *169th Street Station (MR-255) is not feasible for both APGs and PSDs as their implementation would create non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" width requirement for ADA compliant wheelchair movement would not be met at all stairs. Remaining widths would be approximately 25" (see figure 1).*

Description

169th Street Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of the side platforms are approximately 11'-4". Columns are spaced 15' on center and columns faces are 3'-4" from the edge of the platform. There is typically 2'-0" between the column and railing at all staircases. There are five staircases along each platform, all of which would not comply with the 32" width requirement for wheelchair movement. Columns divide the path between the stairs and the platform edge. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

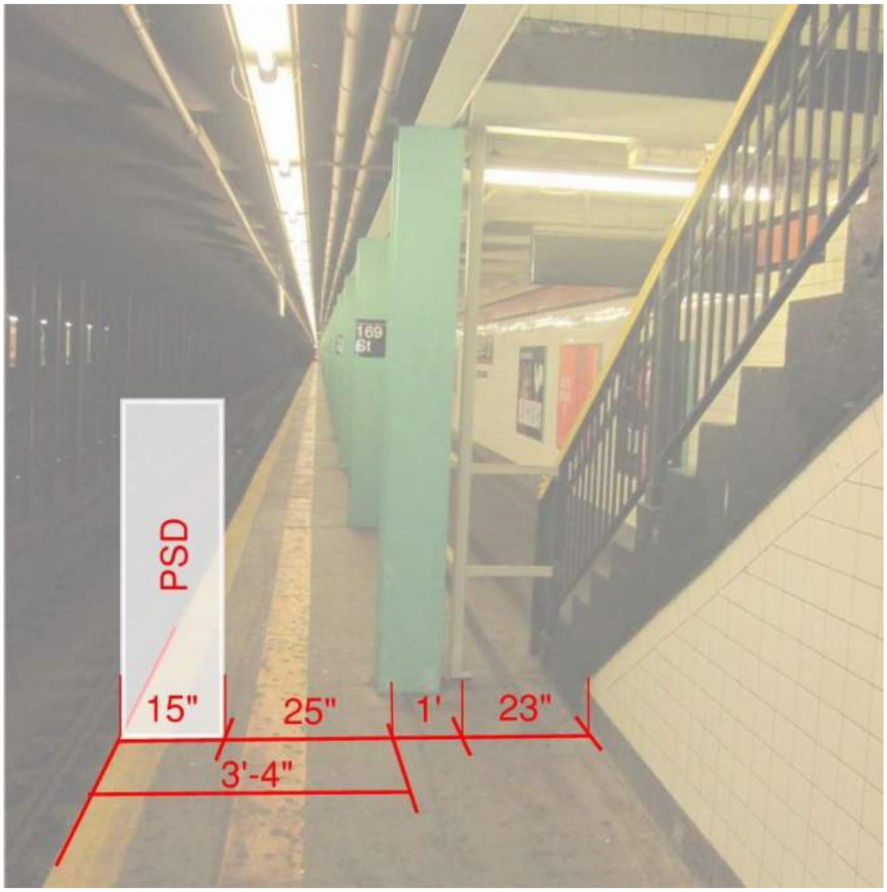

Figure 1 – Non-compliant ADA condition at stairs (typical)- 169th Street Station

1.3 MR-256 | Parsons Boulevard Station

__Summary:__ Parsons Boulevard Station (MR-256) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). This condition occurs at all stairs on the local track edge of both platforms.

Description

Parsons Boulevard Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 19'-6". There are five staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-4" away from all platform edges. The stairs are not centered on the platform, but shifted towards the local track edges. These stair are flanked on one side by the typical station column (3'-4" from the platform edge). Typically, the stairs are 9' from the express platform edge. See figure 2 for typical edge conditions at local and express sides of the platform. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

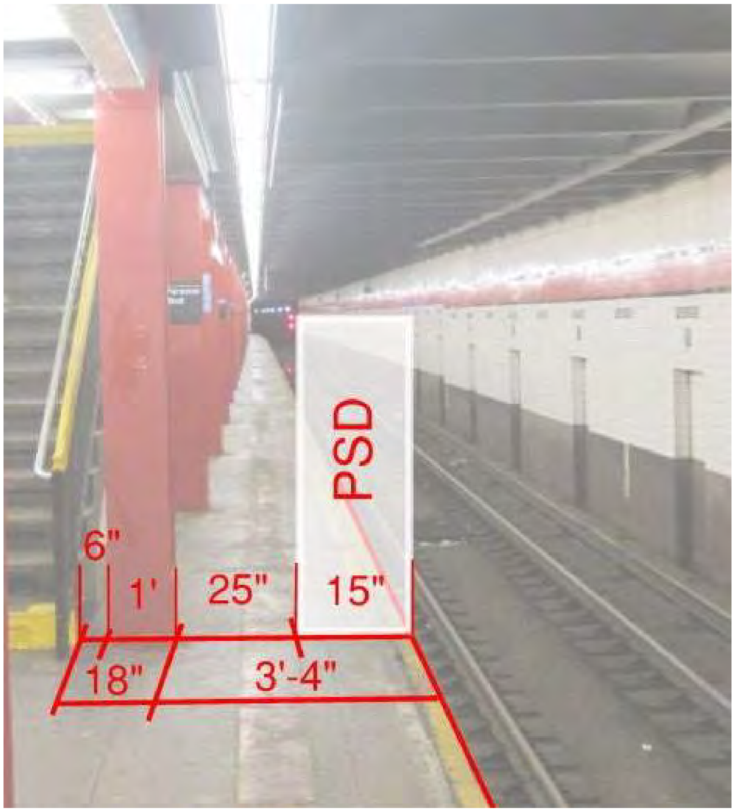

Figure 1 – Non-compliant ADA condition at stair (typical on local edge only) – Parsons Blvd. Station

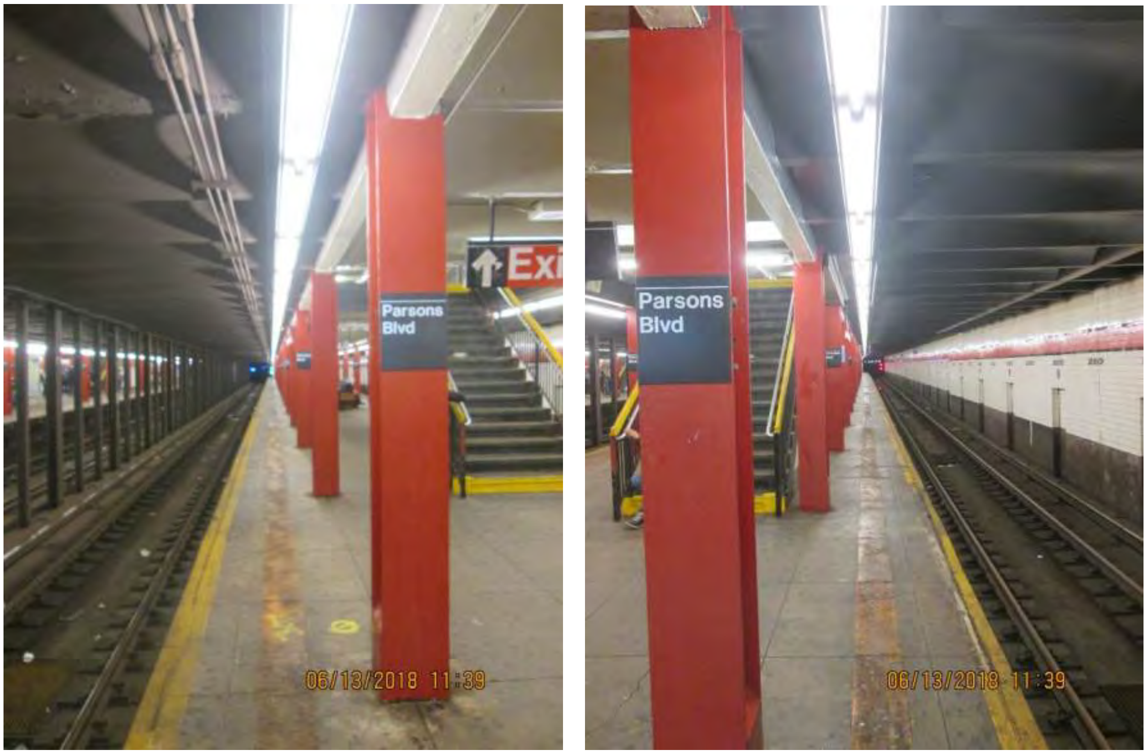

Figure 2 – Typical edge conditions | Express condition (left) and local condition (right)– Parsons Blvd. Station

1.4 MR-257 | Sutphin Boulevard Station

Summary: *Sutphin Boulevard Station (MR-257) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). This condition would occur at all stairs on both platforms.*

Description

Sutphin Boulevard Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 11'-4". There are six staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns divide the path between the stairs and the platform edge. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-4"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

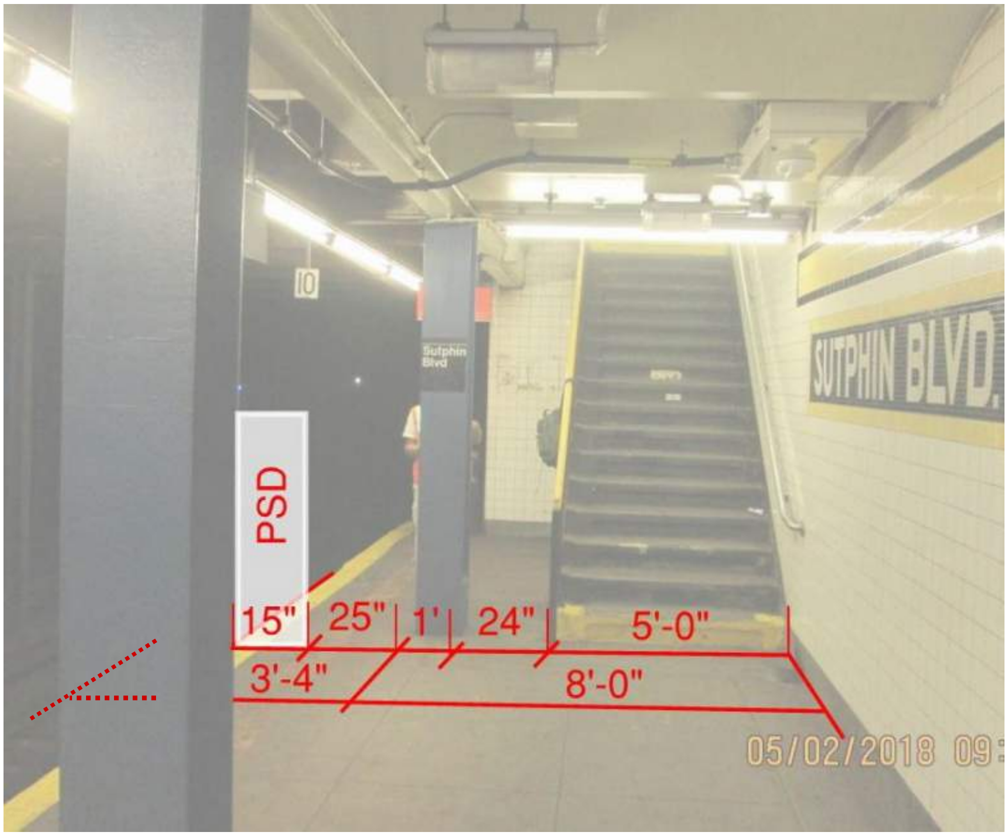

Figure 1 – Non-compliant ADA condition at stairs (typical)- Sutphin Blvd. Station

1.5 MR-258 | Briarwood Station

Summary: *Briarwood Station (MR-258) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 23" (see figure 1). This condition occurs at all stairs on both platforms.*

Description

Briarwood Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 11'-4". There are four staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns divide the path between the stairs and the platform edge. Column spacing along the length of the platform is approximately 15'-0" on center and column faces are typically 3'-2" to the edge of the platform. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-2"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 23" would not allow for ADA compliant wheelchair movement.

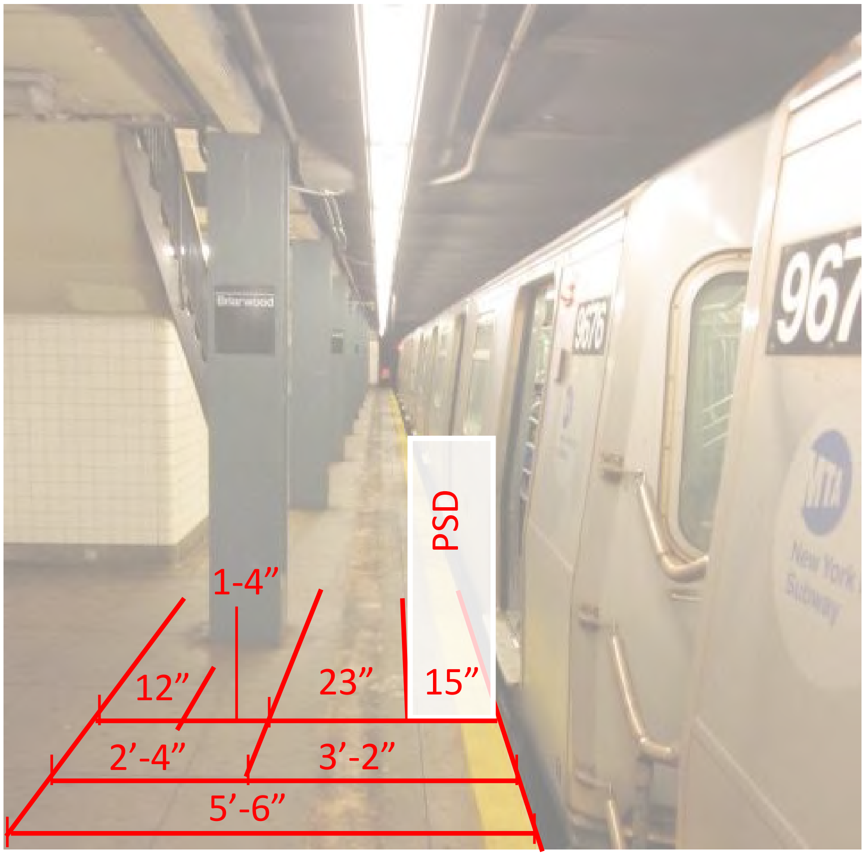

Figure 1 – Non-compliant ADA condition at stairs (typical)- Briarwood Station

1.6 MR-259 | Kew Gardens-Union Turnpike Station

Summary: *Kew Gardens-Union Turnpike Station (MR-259) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met on one side of the platform (see figure 1). The remaining width would be 24".*

Description

Kew Gardens-Union Turnpike Station is a below-grade station consisting of two mildly curved center/island platforms. The cast-in-place concrete platforms are accessed via two mezzanines. There are six stairs and an elevator located on each platform. The platform is approximately 19'-0" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-3" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-3"). All of the stairs are off center as shown in figure 1. Although there is adequate clear space on one side of the platform, the implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement at the other side. Similarly, the elevators are shifted towards one side of the platform not allowing for 32" clearance (at one platform edge) for ADA compliant wheelchair movement. Both platform edges need to comply in order for the station to be ADA compliant for the implementation of a platform edge barrier.

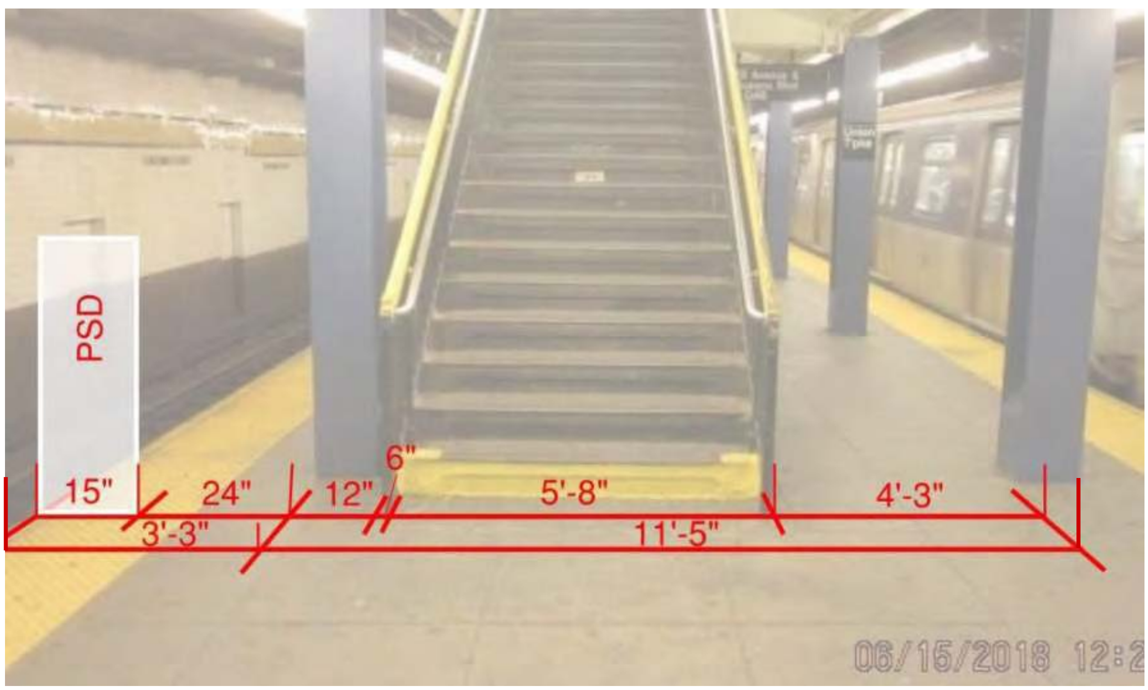

Figure 1 – Non-compliant condition on one side of the center/island platform- Kew Gardens-Union Turnpike

1.7 MR-260 | 75th Avenue Station

Summary: *75th Avenue Station (MR-260) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met (see figure 1).*

Description

75th Avenue Station is a below-grade station consisting of two straight side platforms. The cast-in-place concrete platforms are accessed via a large mezzanine level. There are four stairs located in various locations along the length of each platform. The platforms are approximately 11'-4" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Columns are 1'-10" away from stairs (not an ADA compliant path). Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). In the implementation of a platform edge barrier, this clearance would be 25".

Figure 1 – Non-compliant condition at stairs (typical) - 75th Avenue

1.8 MR-221 | 21st Street- Queensbridge Station

Summary: *21st Street-Queensbridge Station (MR-221) is feasible for both APGs and PSDs. There are two signal boxes that would have to be relocated in the implementation of a platform edge barrier. Structural work would only be required in the implementation of APGs (see structural report; Appendix B) Electrical capacity at this station is adequate to support a APG/PSD system.*

Description

21st Street-Queensbridge Station is a below-grade station with two straight side platforms (see figure 1). The platform structure is cast-in-place concrete. Back-of-house elements are located at the mezzanine level and at the platform level away from passenger areas. The platforms are mostly column free. On both platforms, there are five 2' wide cylindrical columns which are 7'-6" away from the platform edge. Typically, the platform widths are approximately 11'-2". These columns are in a double height space that is open to the mezzanine level. On each platform, one train signal box hangs over the platform edge, with a vertical clearance of 7'-4". Ceiling heights vary throughout the station, ranging from 9'-2" to 20'-0".

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling heights vary throughout the station (see figure 4). Train signal boxes on would need to be relocated in the implementation of full height PSDs (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the Coney Island-bound platform adjacent to the elevators. The proposed room dimension is 7'-0" x 27'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

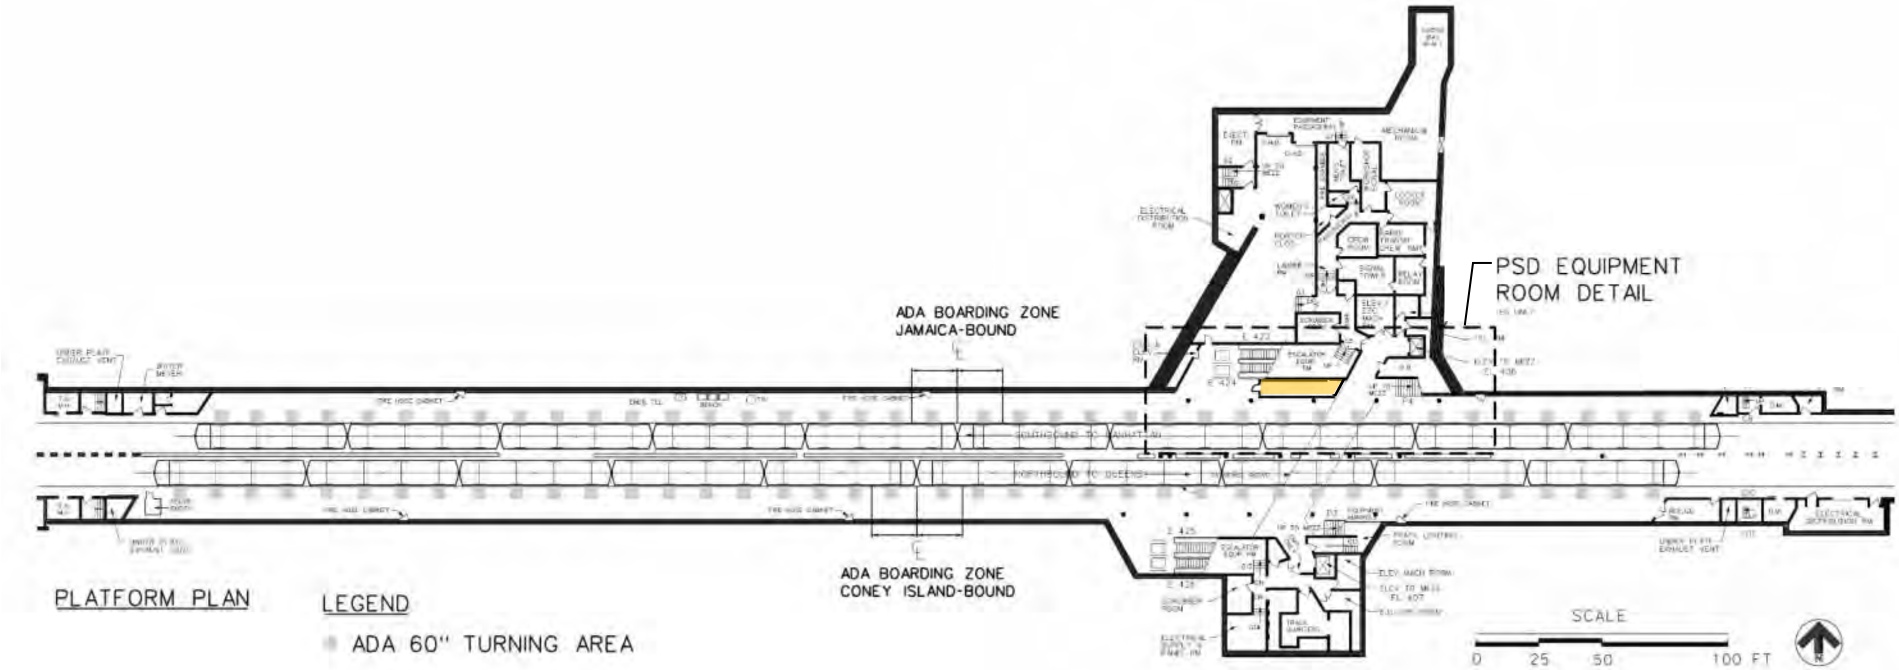

Figure 1 – Station Plan- 21st Street- Queensbridge Station

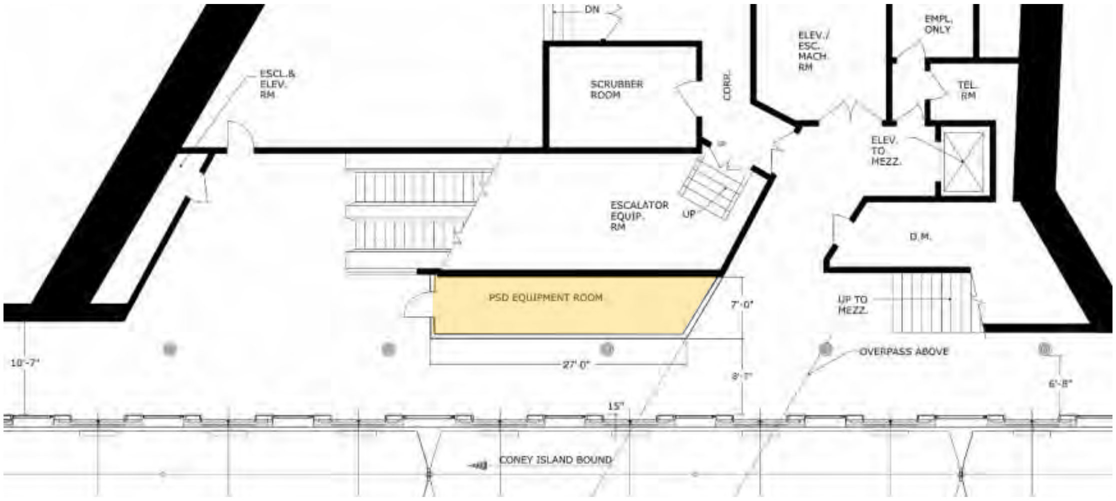

Figure 2 – PSD Equipment Room Detail – 21st Street- Queensbridge Station

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

The 2012 NYCT conditions survey gave the platform edges an average rating of 2.5. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

None

Lighting:

Existing lighting: Along the majority of the platform, linear florescent lighting is perpendicular to the platform edge and located between structural members. In the double height area, there are recessed florescent fixtures and can lighting. It is unlikely that the existing lighting would need to be modified at this station.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station. MRN 221 has adequate capacity to support the implementation of a APG/PSD system.

Station
Power Capacity Analysis

NYCT Station MR Number	221
Station Name	21st Street Queensbridge
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	404.0
Apparent Power (kVA)	505.0
Station Peak Demand Load, Max Current, (A)	1402.8
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	1597
Station Service Power Capacity, (Main SB or SG Rating), (A)	3000
Service Spare Capacity, (A)	1403
Is Electrical Service Adequate?	Yes
Notes	Station does not have 1 line diagram. This analysis is based on one meter reading only.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $39.8M to install PSDs (See Appendix E)

Figure 3 – Typical platform view with signal box- 21st Street- Queensbridge Station

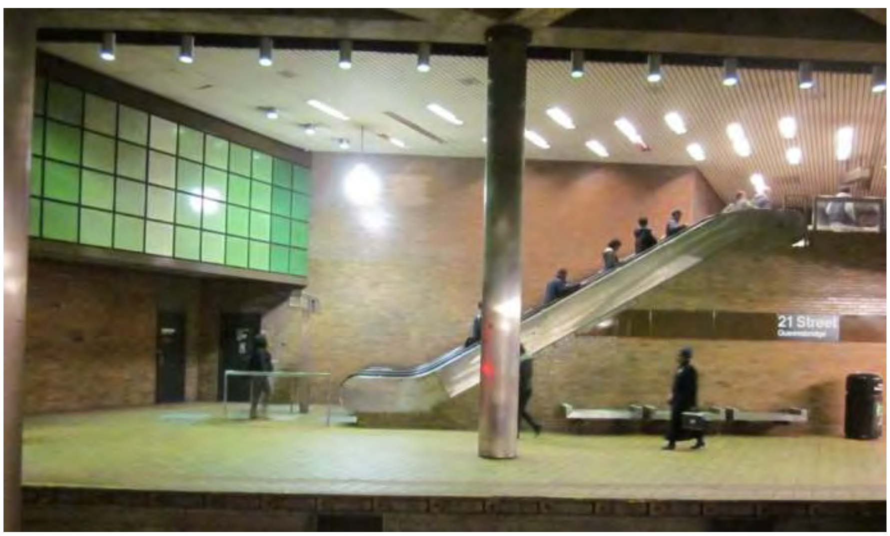

Figure 4 – View of double-height area - 21st Street- Queensbridge Station

1.9 MR-222 | Roosevelt Island Station

Summary: *Roosevelt Island Station (MR-222) is feasible for both APGs and PSDs. There are a variety of conditions in this station including curved or straight walls and ceilings, varying ceiling heights, and different lighting supports. Structural work would only be required in the implementation of APGs (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system.*

Description

Roosevelt Island Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Back-of-house elements are located at the end of the platforms and at the mezzanine level. The platforms are column free. Typically, the platform widths are approximately 12'-0". There are a variety of platform conditions, in which the platform is a combination of curved and/or straight walls and ceilings. Ceiling heights vary from 7'-10" to 12'-10". Figures 3 and 4 represent typical platform wall and ceiling combinations as well as various lighting conditions.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north-end of the Jamaica-bound platform. The proposed room dimension is 7'-0" x 27'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support

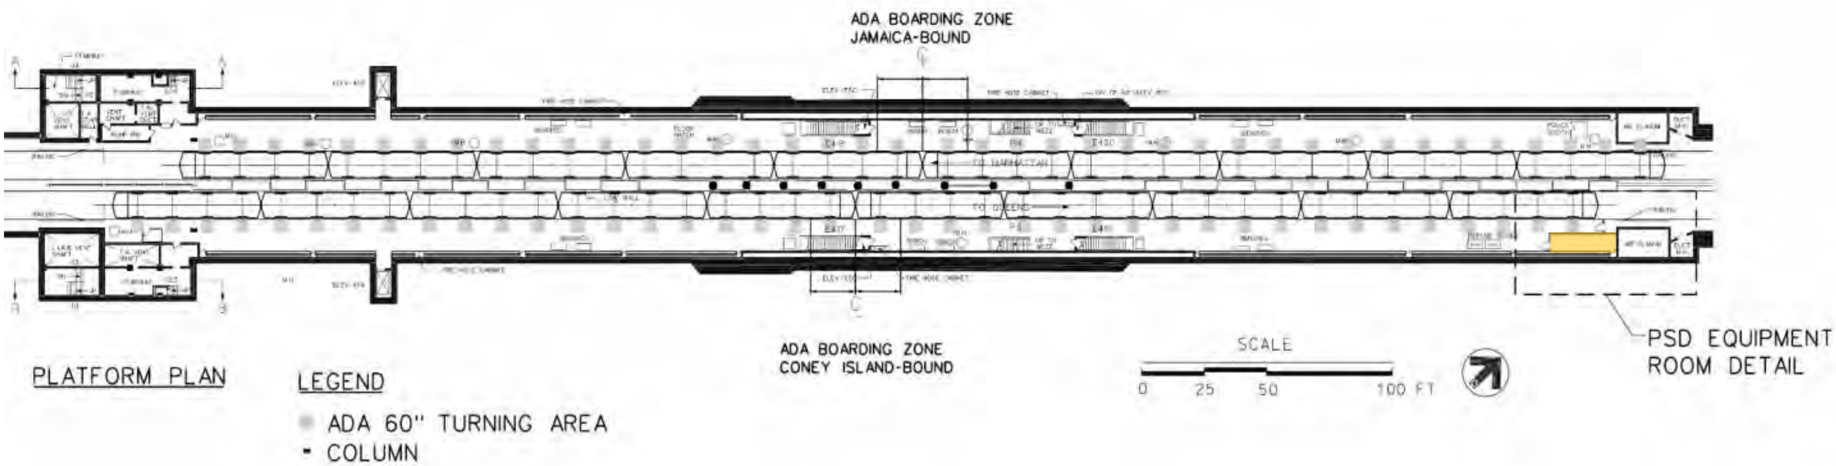

Figure 1 – Station Plan- Roosevelt Island Station

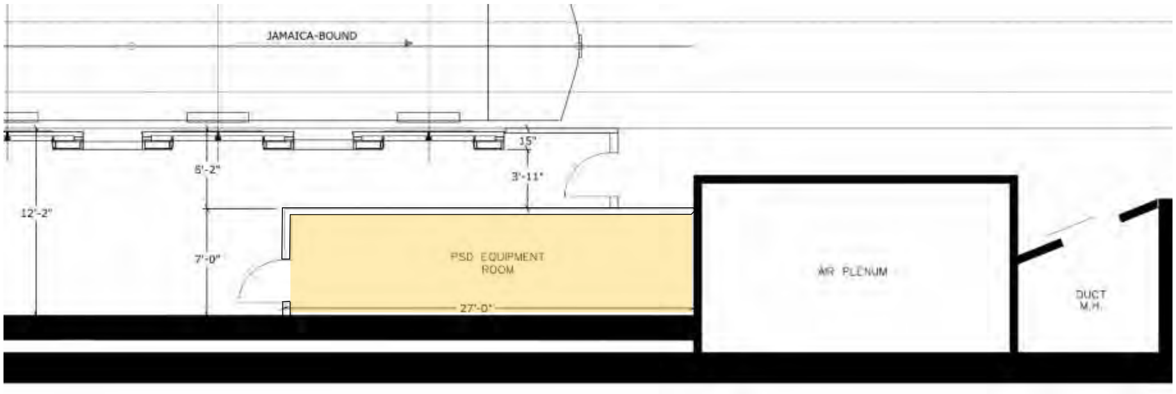

Figure 2 – PSD Equipment Room Detail – Roosevelt Island Station

half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

The 2012 NYCT conditions survey gave the platform edges an average rating of 3.25. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: Linear fluorescent lighting is surrounded by a continuous 1'-6" tube fixture. The fixtures are 20" from the edge of the platform and have a vertical clearance of 7'-10". As the ceiling heights vary, the lighting is either suspended with angular supports some of which extend over the platform edge (figure 3) or mounted on the ceiling (figure 4). There is also cove lighting along the top of the back wall of the platforms.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station. MRN 222 has adequate capacity to support the implementation of a APG/PSD system.

Station
Power Capacity Analysis

NYCT Station MR Number	222
Station Name	Roosevelt Island
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	555.8
Apparent Power (kVA)	694.8
Station Peak Demand Load, Max Current, (A)	1930.0
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	2125
Station Service Power Capacity, (Main SB or SG Rating), (A)	5500
Service Spare Capacity, (A)	3375
Is Electrical Service Adequate?	Yes
Notes	Station has 2500 A service @ 460 Volt (not 208 V) with max demand of 555.8 KW. We have converted ratings values to 208 V. Station does not have 1 line diagram.

Table 1. MRN 222 Power Capacity Analysis

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.5M to install APGs and $40.8M to install PSDs (See Appendix E)

Figure 3 – Typical platform view featuring curved walls and ceilings- Roosevelt Island Station

Figure 4 – Platform view featuring low planar ceiling with cured and straight walls- Roosevelt Island Station

1.10 MR-223 | Lexington Avenue-63rd Street Station

Summary: *Lexington Avenue-63rd Street Station (MR-223) is feasible for both APGs and PSDs. The recent renovation work at this station conceals the structure at the platform edge. Modifications to this renovation work may be needed to accommodate a PSD system. Structural work would only be required in the implementation of APGs (see structural report; Appendix B). It is assumed that power is adequate.*

Description

Lexington Avenue- 63rd Street Station is a below-grade station with two straight center/island platforms (see figure 1). The platforms are stacked; the upper level provides Coney Island-bound service, while the lower level provides Jamaica-bound service. These platforms also provides Q-line service, similarly with the directions of travel on separate platform levels. This station was renovated in the Second Avenue Subway expansion (opened January 2017). Four elevators are located in a vestibule at the east-end of the station. The platform structure is cast-in-place concrete. Back-of-house elements are located at the end of the platforms and at the mezzanine levels. At the middle of both platforms there are six columns in two rows spaced 8'-0" apart with column faces 4'-6" from the edge of the platform. In addition to these columns, the lower level has a row of columns centered on the platform width spaced 15'-0" on center. At the upper level, there are ceiling mounted metal panels that are angled and extend beyond the platform edge (see figure 3). At the lower level, there are horizontal metal mesh panels covering the beams at and beyond the platform edge (see figure 4).

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Due to the treatment of the ceilings at and beyond the platform edge, modification of metal panels may be necessary to create the supporting structure of a full height system.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

This station will need two equipment rooms as there are four platform edges. For the two F-line platform edges, one room can be located in the middle of the lower level platform between the existing columns. The proposed room dimension is 12'-0" x 16'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

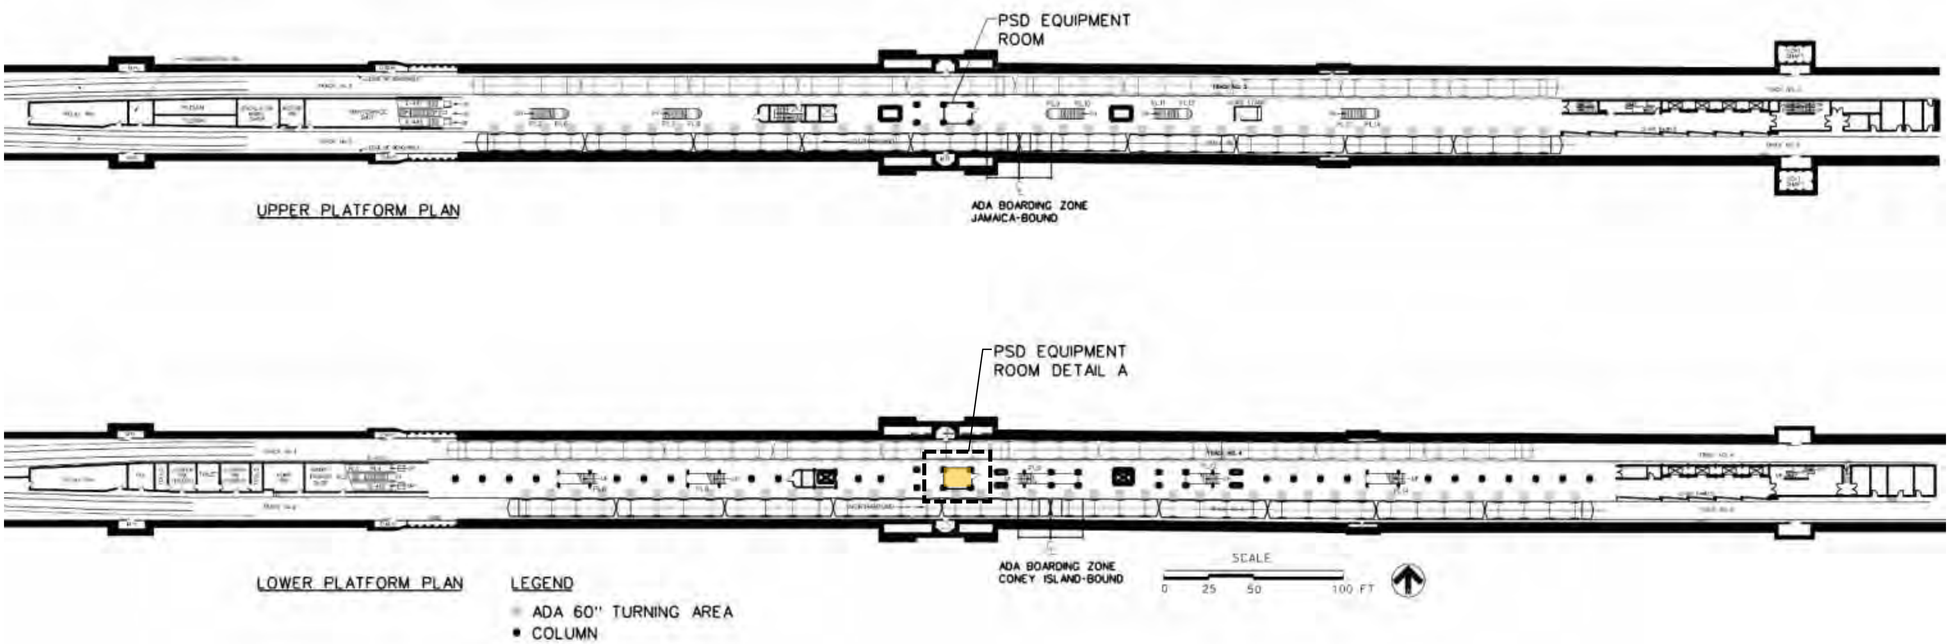

Figure 1 – Station Plan- Lexington Ave.-63rd St. Station

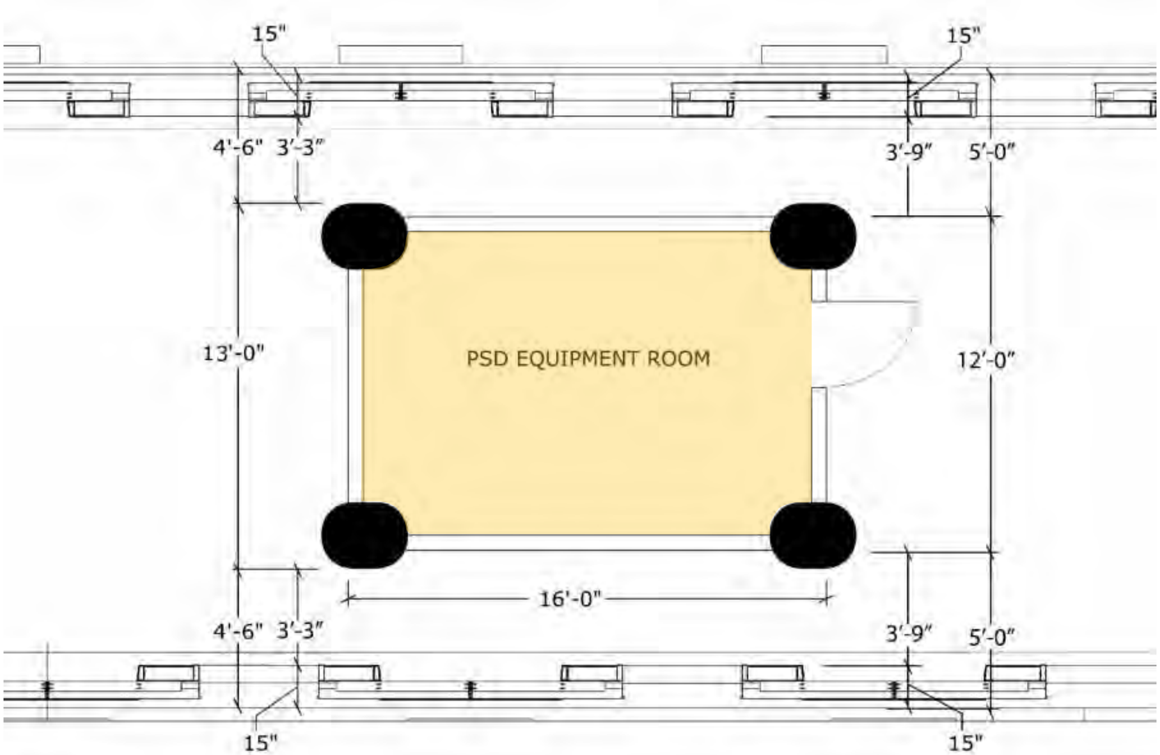

Figure 2 – PSD Equipment Room Detail – Lexington Ave.-63rd St. Station

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

As this station was recently renovated, the platform edge score from the 2012 NYCT conditions survey is not a reflection of current conditions.

Platform obstructions within 5' of edge:

Coney Island-bound: There are three columns that are 4'-7" away from the platform edge.

Jamaica-bound: There are three columns that are 4'-7" away from the platform edge.

Lighting:

Existing lighting: Lighting comprises of 1'-6" fluorescent tubes recessed above removable ceiling panels, and encased fluorescent tubes installed approximately 60" away from the platform edge

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.6M to install APGs and $39.3M to install PSDs (See Appendix E)

Figure 3 – Platform edge condition on the lower level (Coney Island-bound)- Lexington Ave.-63rd St. Station

Figure 4 –Platform edge condition on the lower level (Jamaica-bound)- Lexington Ave.-63rd St. Station

1.11 MR-224 | 57th Street Station

Summary: *57th Street Station (MR-224) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform. At some stairs, the 32" minimum requirement for wheel chair circulation would not be met on one side of the platform. See figure 1 for the typical non-compliant condition occurring on one side of the platform.*

Description

57th Street Station is a below-grade station consisting of one straight center/island platform. The cast-in-place concrete platforms are accessed via a mezzanine. There are six stairs on the platform. Four of these stairs are shifted towards one side of the platform adjacent to columns. The platform is approximately 23'-0" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). Four of the six stairs are off center as shown in figure 1. Although there is adequate clear space on one side of the platform, the implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement at the other side. Both platform edges need to comply in order for the station to be deemed feasible for the implementation of a platform edge barrier.

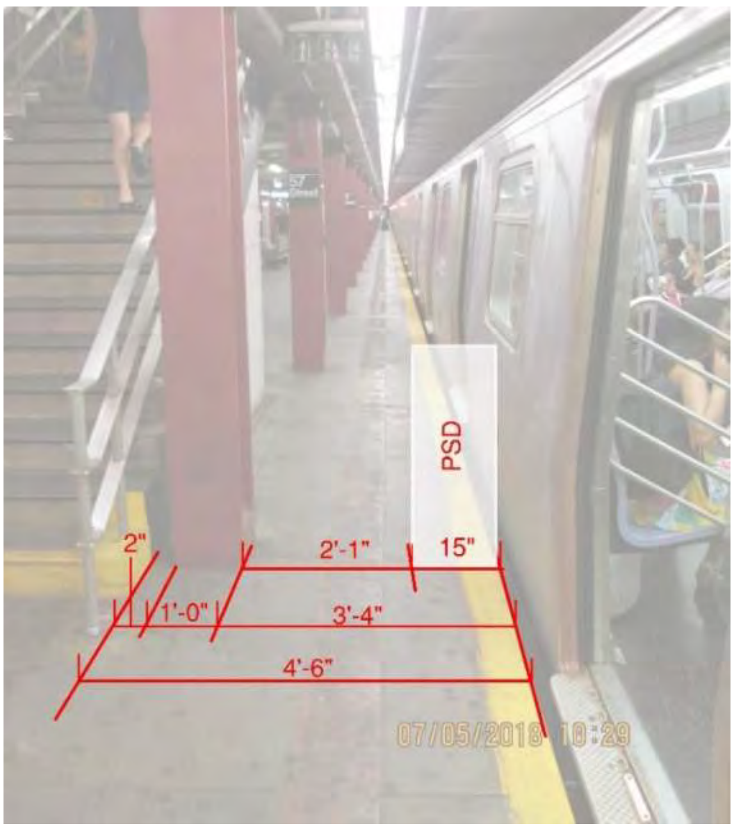

Figure 1 – Non-compliant ADA condition on one side of the center/island platform- 57th Street

1.12 MR-232 | 2nd Avenue Station

Summary: *2nd Avenue (MR-232) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. There a flue vents located at the center of both platforms, flanked by columns on both sides of the platform. The ADA constraints occur due to columns surrounding the vent flues on both center/island platforms. Currently, the distance between the column and the edge of the platform is 36" and the spacing between the column and the wall of the vent flue is 18" on one side and 30" on the other. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at vent flues as the remaining width would be 21" (see figure 1).*

Description

2nd Avenue Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 19'-4". A vent is centered on both the Jamaica-bound and Coney Island-bound platforms. Currently, there is an ADA compliant path of travel between the column face and the platform edge (3'-0"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 21" would not allow for ADA compliant wheelchair movement.

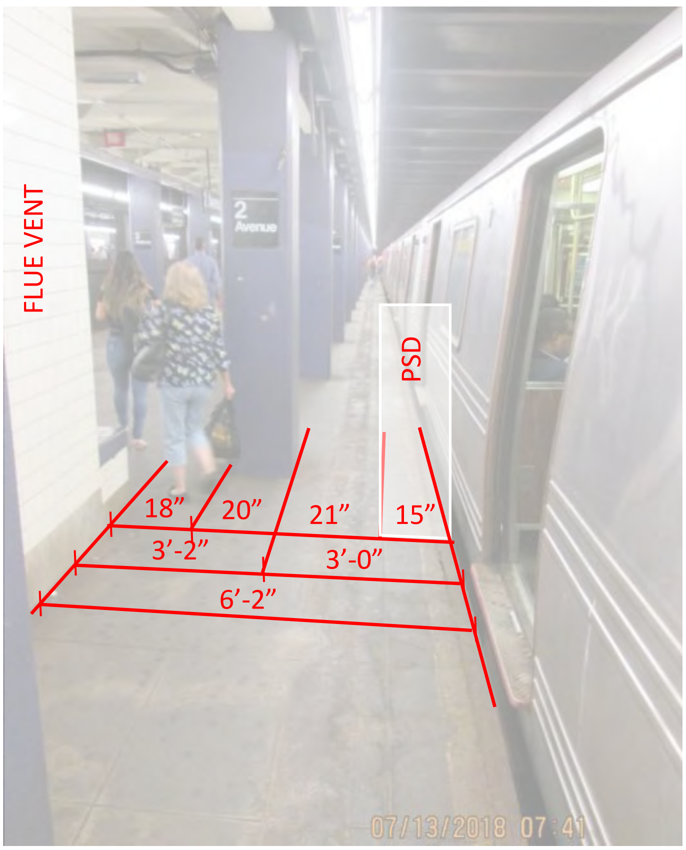

Figure 1 – Non-compliant ADA condition at flue vent- 2nd Avenue Statio

1.13 MR-233 | Delancey Street Station

Summary: *Delancey Street Station (MR-233) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, there are two locations along the Jamaica-bound platform that would result in non-compliant conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met due to the location of an existing escalator and an escalator pit room. In the implementation of a platform edge barrier, the widest remaining widths in either situation would be 30" and 26" respectively (see figures 1 and 2).*

Description

Delancey Street Station is a below-grade station with straight side platforms. The platform structure is cast-in-place concrete. The width of both side platforms is approximately 12'-8". Columns are spaced 15'-0" on center with faces 3'-0" from the platform edge. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-0"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32" at two specific locations on the Jamaica-bound platform (see figures 1 and 2). Remaining widths would not allow for ADA compliant wheelchair movement.

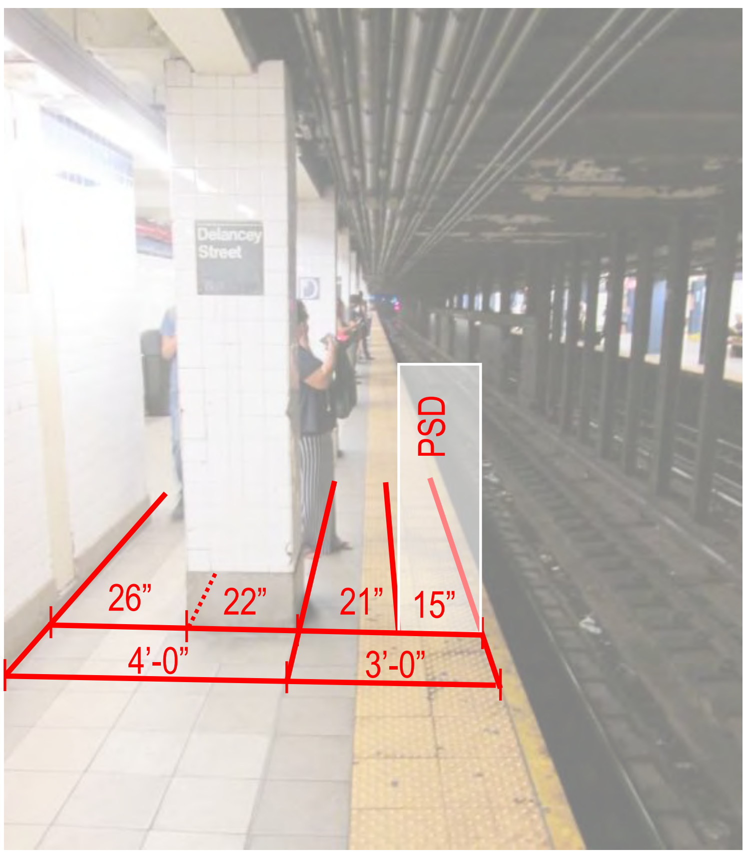

Figure 1 – Non-compliant ADA condition at escalator 328- Delancey Street Station

1.14 MR-234 | East Broadway Station

Summary: *East Broadway Station (MR-234) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at five of the seven stairs/escalators. The remaining width would be 25" (see figure 1). The stairs/escalators at this station are typically off-center, located closer to the local track platform edge. Currently, columns divide the 6'-0" width between the platform edge and the stairs/escalators.*

Description

East Broadway Station is a below grade station with a straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 17'-6". Columns are spaced 15'-0" on center with column faces 3'-4" from the platform edge. Passengers requiring an ADA compliant path can currently move in the 3'-4" space between the stairs and platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

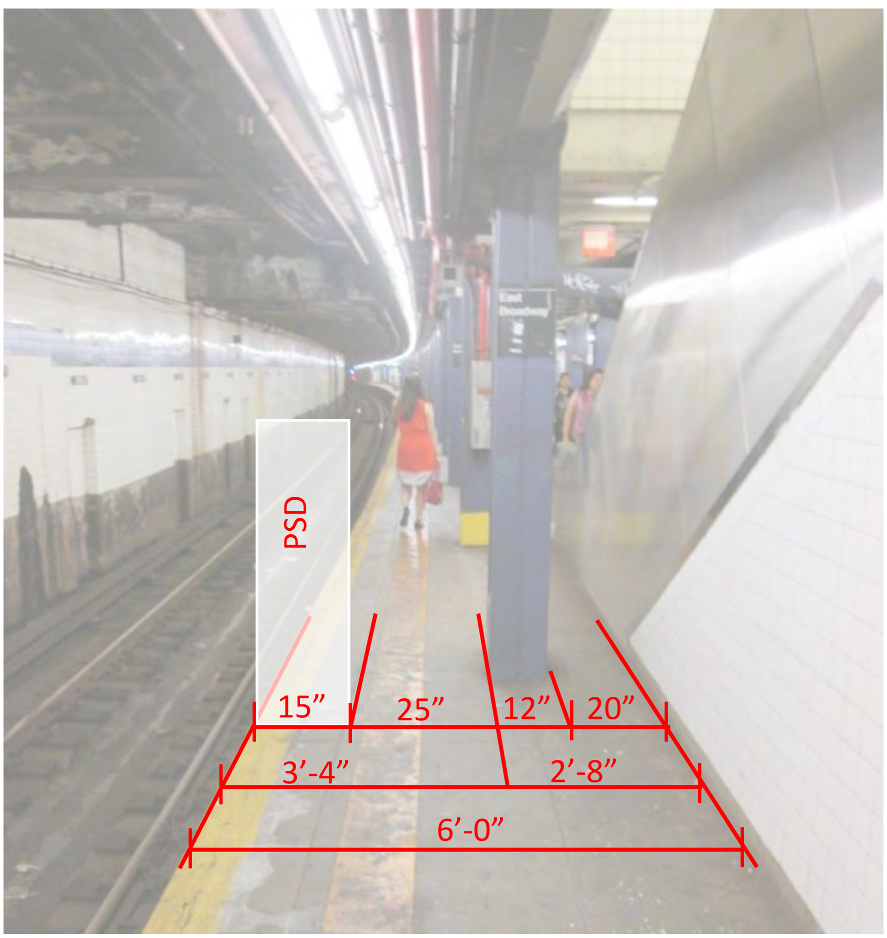

Figure 1 – Non-compliant ADA condition at stairs/escalator (typical)- East Broadway Station

1.15 MR-235 | York Street Station

Summary: *York Street Station (MR-235) is feasible for both APGs and PSDs. There is area at the south-end of the platform where a PSD equipment room can be located. Platform structural work will be required to support the requirements of an APG or PSD system (see structural report; Appendix B). It is assumed that existing power is adequate.*

Description

York Street Station is a below-grade station with a straight center/island platform (see figure 1). The platform has one stair at the north-end of the platform. The platform structure is cast-in-place concrete. Back-of-house elements are situated in the mezzanine, which is connected to the station platform through a ramp passageway. The platform width is approximately 18'-8" wide. There are two rows of columns that are spaced 15'-0" on center, with column faces 2'-8" from the platform edge. The distance between the two rows of columns is typically 11'-0". For an overall station plan, see figure 1. See figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted and hung conduits below the platform edge would need to be relocated to accommodate the requirements of the APG system.

Equipment Room

One room can be accommodated at the south-end of the platform. The proposed room dimension is 12'-0" x 16'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Structural work should be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair

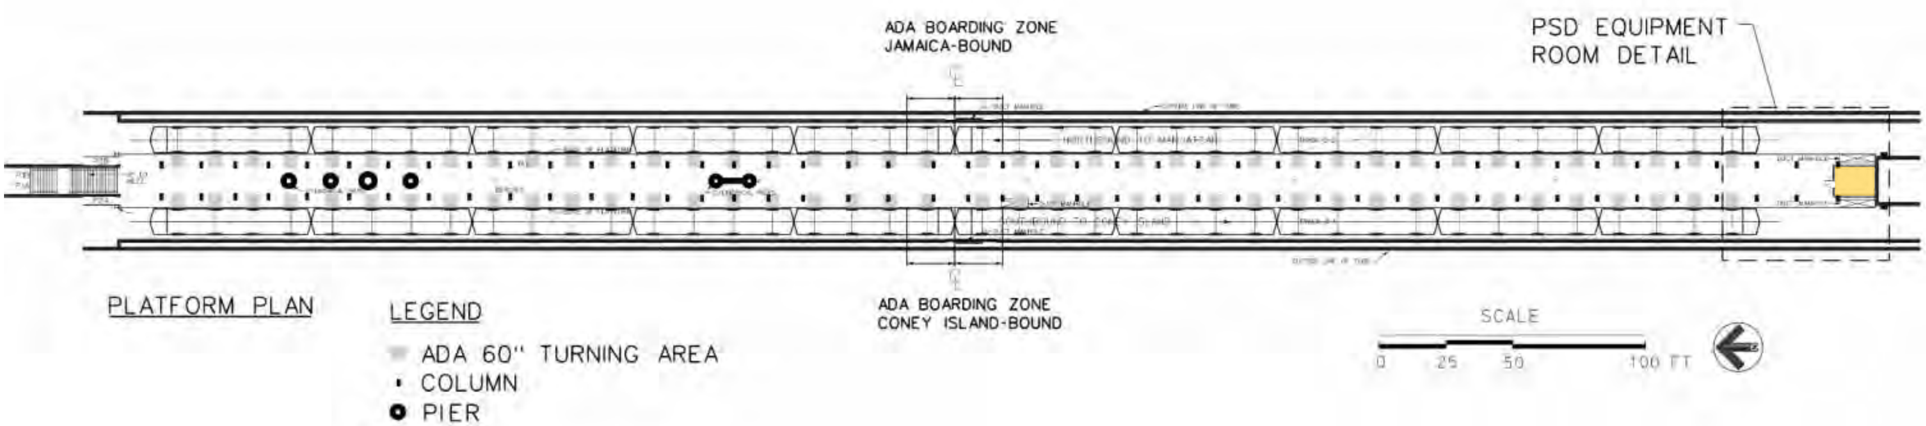

Figure 1 – Station Plan-York Street Station

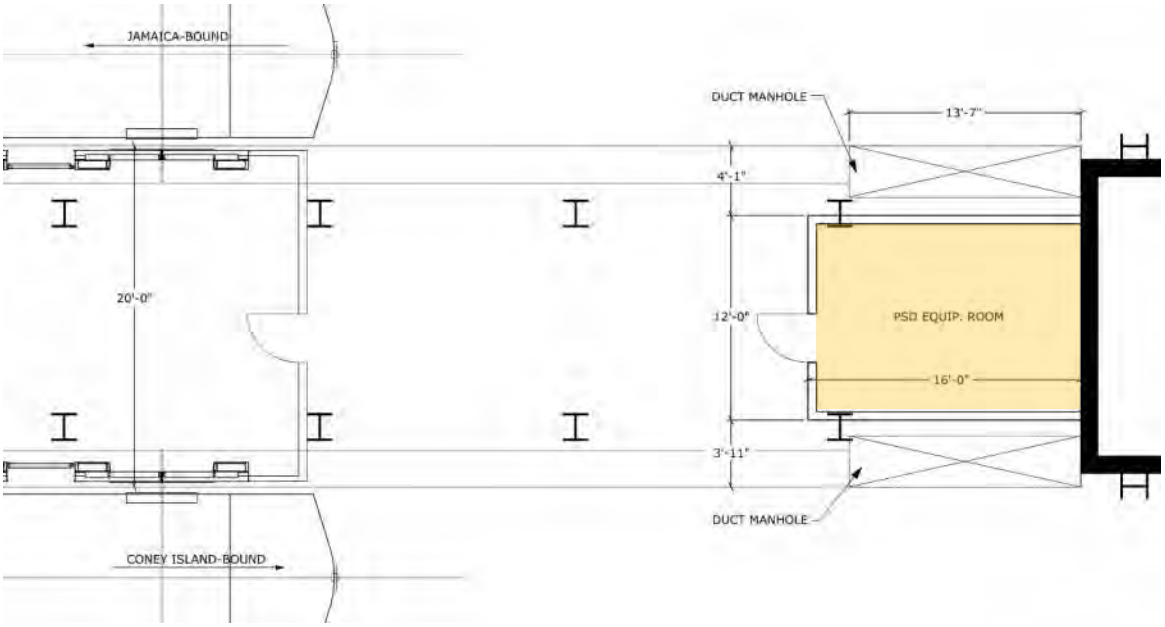

Figure 2 – PSD Equipment Room Detail – York Street Station

Platform obstructions within 5' of edge:

All columns are 32" from the platform edge. Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A.

Lighting:

Existing lighting: Linear fluorescent; approximately 1' from the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.5M to install APGs and $41.2M to install PSDs (See Appendix E).

Figure 3– Typical platform view- York Street Stati

1.16 MR-174 | Jay Street-MetroTech Station

Summary: *Jay Street-MetroTech Station (MR-174) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. The platforms serving the 'F' line also serve the 'A' and 'C' lines. In the implementation of a platform edge barrier, the 32" minimum pinch width requirement for ADA compliant wheelchair movement would not be met at several stairs on both platforms. These stairs are not centered on the width of the platform, but are closer to the 'A' and 'C' track side of the platform. In these conditions, the remaining width would be 27" (see figure 1). Although the minimum required circulation width is met on one side of the platform, compliance is required on both sides of the platform in order to be feasible.*

Description

Jay Street-MetroTech Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete and serves the 'F', 'A', and 'C' lines. The width of the platform is approximately 24'-8". Columns are spaced 15'-0" on center with column faces 3'-6" away from the platform edge. The columns on the northbound (Jamaica-179th Street) platform are exposed, while on the southbound (Coney Island-Stillwell Avenue) platform have a tile surround. On both platforms, column faces are 3'-6" from the platform edge. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-6"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 27" would not allow for ADA compliant wheelchair movement.

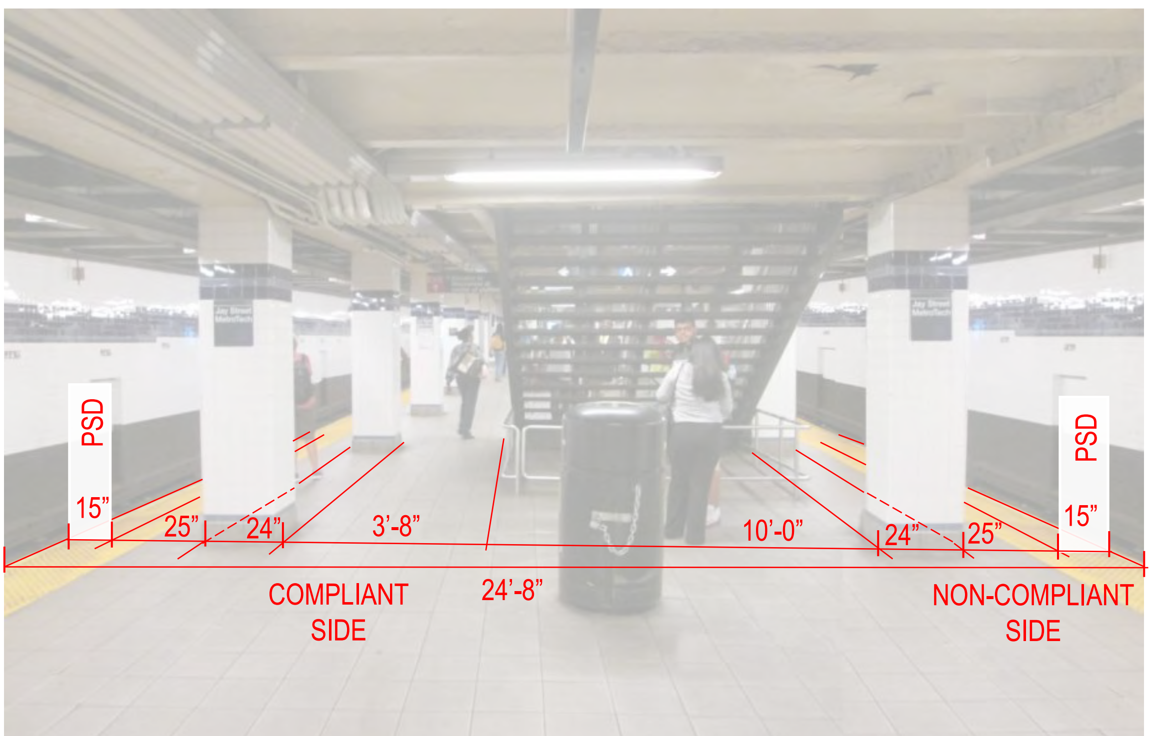

Figure 1 – Non-compliant ADA condition on one side of platform (southbound)- Jay Street- MetroTech Station

1.17 MR-244 | Ditmas Avenue Station

Summary: *Ditmas Avenue Station (MR-244) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

Ditmas Avenue Station is an elevated station consisting of two side platforms. Both platforms are 11'-4" wide. The platform is straight with a row of a columns against the back wall of the platform. The canopy covers the entirety of the platform length. See figure 1 for a general platform view of Ditmas Avenue Station. The stair at the north-end of the platform is 3'-6" away from the platform edge. In the implementation of a platform edge barrier, the remaining width at the stair would be insufficient for wheelchair movement.

Figure 1– Non-compliant ADA Condition – Ditmas Avenue Station

Figure 2– Precast T-Beam platform – Ditmas Avenue Station

1.18 MR-245 | 18th Avenue Station

Summary: *18th Avenue Station (MR-245) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

18th Avenue Station is an elevated station consisting of two center/island platforms, one of which is currently not in service. The accessible platform is 16'-4" wide. The platform is straight with a row of columns centered on the width of the platform. The canopy covers the entirety of the platform length. The stair at the north-end of the platform is 3'-6" away from the platform edge. In the implementation of a platform edge barrier, the remaining width at the stair would be insufficient for wheelchair movement.

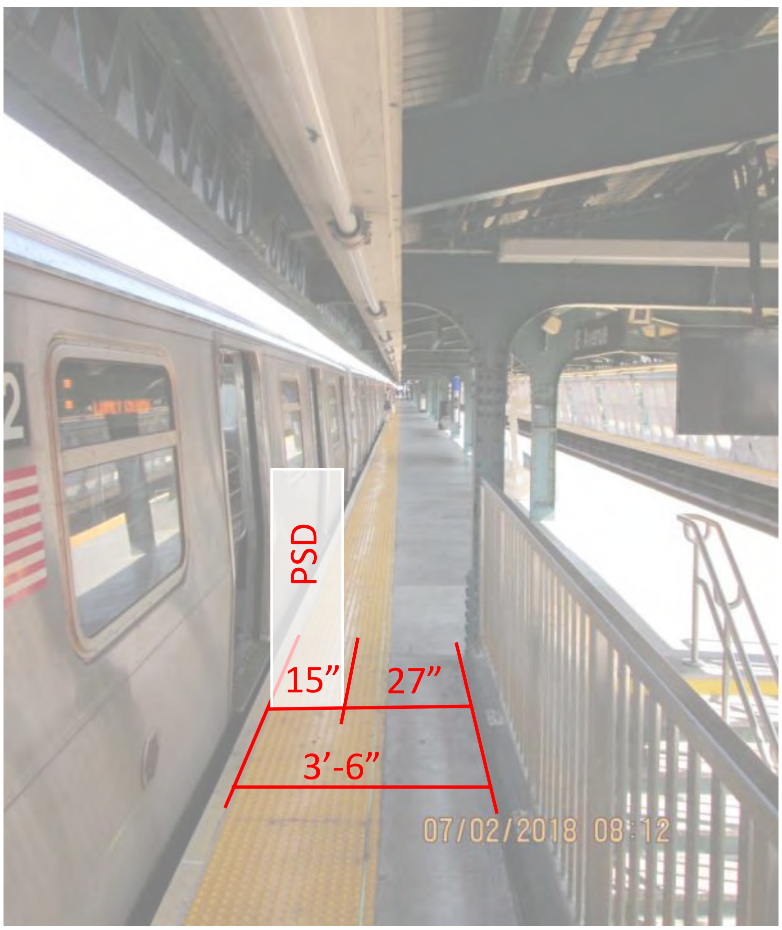

Figure 1– Non-compliant ADA condition – 18th Avenue Station

Figure 2– Precast T-Beam platform – 18th Avenue Station

1.19 MR-246 | Avenue I Station

Summary: *Avenue I Station (MR-246) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the south-end of both platforms, the 32" required width would not be met as the remaining width would be 17" (see figure 1).*

Description:

Avenue I Station is an elevated station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns against the back wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The stair at the south-end of the platform is 32" away from the platform edge. In the implementation of a platform edge barrier, the remaining width adjacent to the stair would be insufficient for wheelchair movement.

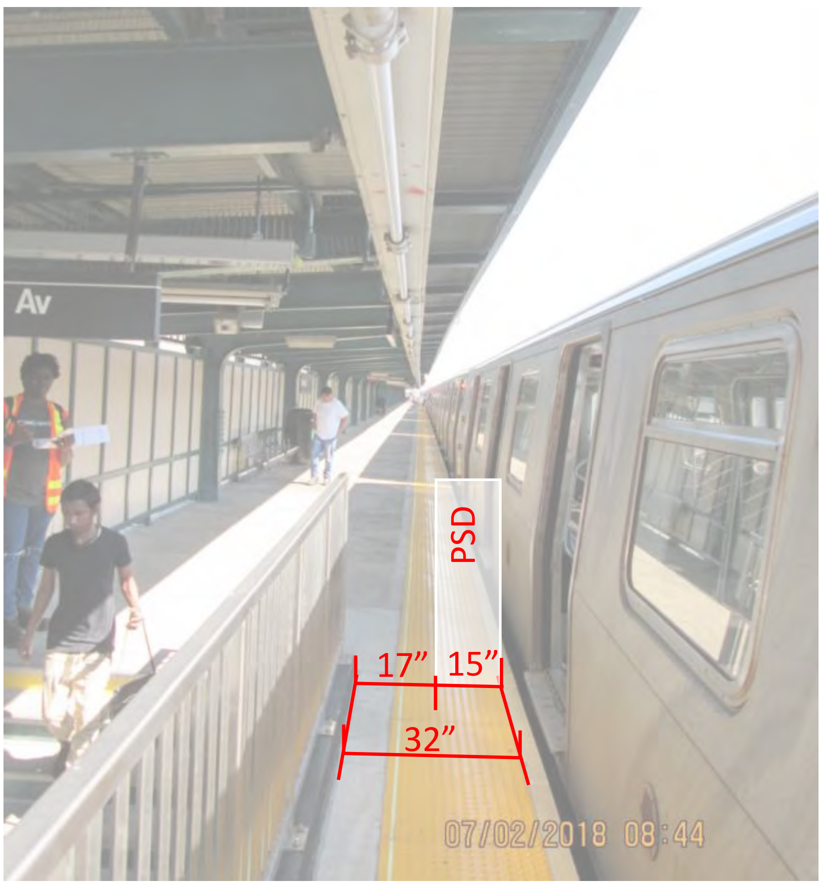

Figure 1– General Platform Condition – Avenue I Station

Figure 2– Precast T-Beam platform – Avenue I Station

1.20 MR-247 | Bay Parkway Station

Summary: *Bay Parkway Station (MR-247) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description:

Bay Parkway Station is an elevated station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns flush with the wall of the platform, which supports the station canopy. The canopy covers approximately half of the platform, which is found to be inadequate cover for a full height PSD system. See figure 1 for a general platform view of Bay Parkway Station.

Figure 1– General Platform Condition – Bay Parkway Station

Figure 2– Precast T-Beam platform – Bay Parkway Station

1.21 MR-248 | Avenue N Station

Summary: *Avenue N Station (MR-248) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

Avenue N Station is an at-grade station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns flush with the wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The stair at the south-end of the platform is 28" away from the platform edge. This width is currently not ADA compliant and the implementation of a platform edge barrier would further exacerbate this condition.

Figure 1– General Platform Condition – Avenue N Station

Figure 2– Precast T-Beam platform – Avenue N Station

1.22 MR-249 | Avenue P Station

Summary: *Avenue P Station (MR-249) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. The stairs are located at the center of the platform and are 3'-8" (44") away from the platform edge. In the implementation of a platform edge barrier, the 32" required width would not be met as the remaining width would be approximately 29" (see figure 1).*

Description:

Avenue P Station is an at-grade station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns against the wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The centrally located stairs are 3'-8" (44") away from the platform edge. The implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement.

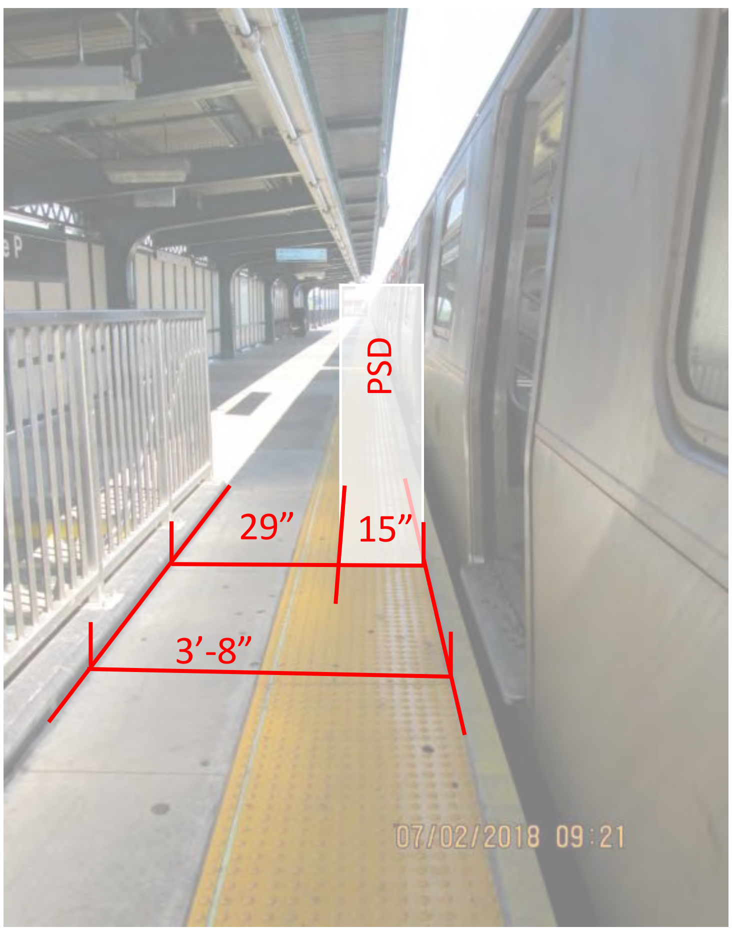

Figure 1– Non-compliant ADA condition at stairs – Avenue P Station

Figure 2– Precast T-Beam platform – Avenue P Station

1.23 Mr-250 | Kings Highway Station

Summary: *Kings Highway Station (MR-250) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description:

Kings Highway Station is an at-grade station consisting of two center/island platforms, one of which is currently not in service. Each center platform is 16'-4" wide. The platform has a singular row of columns supporting a canopy with a spacing of 7'-8" from the column to the edge of the platform. The canopy covers the entirety of the platform length. See figure 1 for a general platform view of Kings Highway Station.

Figure 1– General Platform Condition – Kings Highway Station

Figure 2– Precast T-Beam platform – Kings Highway Station

1.24 MR-251 | Avenue U Station

Summary: *Avenue U Station (MR-251) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, the stair on the south-end of both platforms is located 2'-8" (32") from the platform edge. In the implementation of a platform edge barrier, the remaining width would not allow for ADA-compliant wheelchair movement (see figure 1).*

Description:

Avenue U Station is an elevated station consisting of two center platforms, one of which is currently not in service. Each center platform is 11'-4" wide. The platform is straight with a row of a columns against the wall of the platform. The canopy covers the entirety of the platform length. The stairs at the south-end of both platforms is close to the platform edge and would not allow for ADA-compliant wheelchair movement with a platform edge barrier installed.

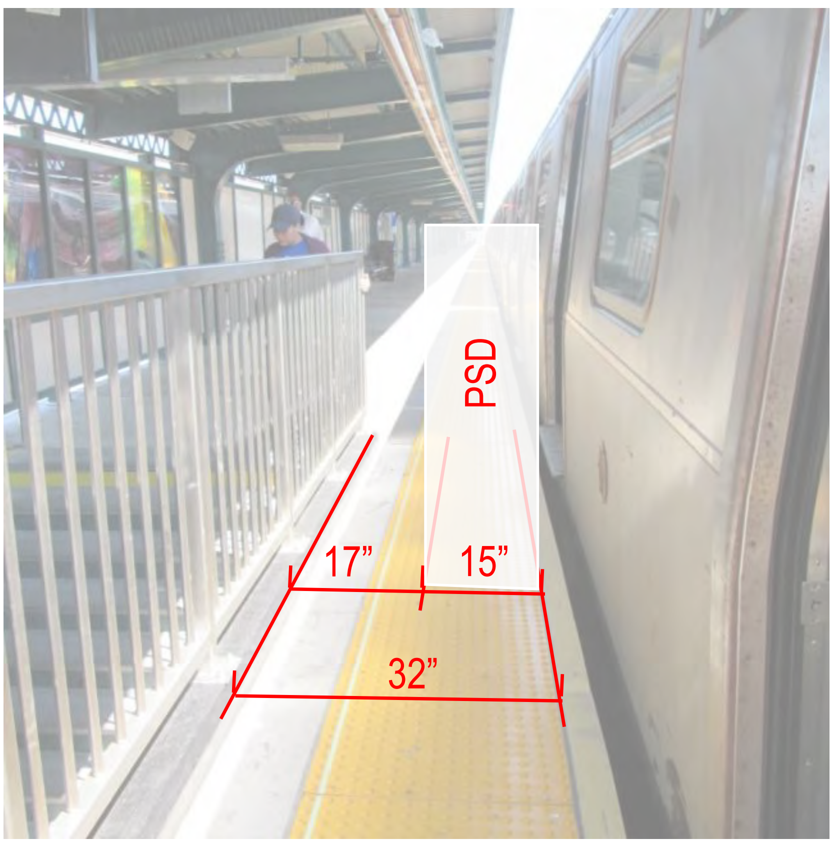

Figure 1– Non-compliant ADA condition at stairs– Avenue U Station

Figure 2– Precast T-Beam platform – Avenue U Station

Table of Contents

1.25 MR-252 | Avenue X Station

Summary: *Avenue X Station (MR-252) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, the stair on the north-end of the Jamaica-bound platform is located 3'-8" (44") from the platform edge. In the implementation of a platform edge barrier, the required 32" width for wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description:

Avenue X Station is an elevated station consisting of two side platforms. Each side platform is approximately 10'-0" wide. The platform is slightly curved with a row of a columns against the back wall of the platform. The canopy covers the entirety of the platform length. The stair at the north-end of the Jamaica-bound platform is close to the platform edge. In this location, the required 32" width for ADA compliant wheelchair movement would not be met with a platform edge barrier installed.

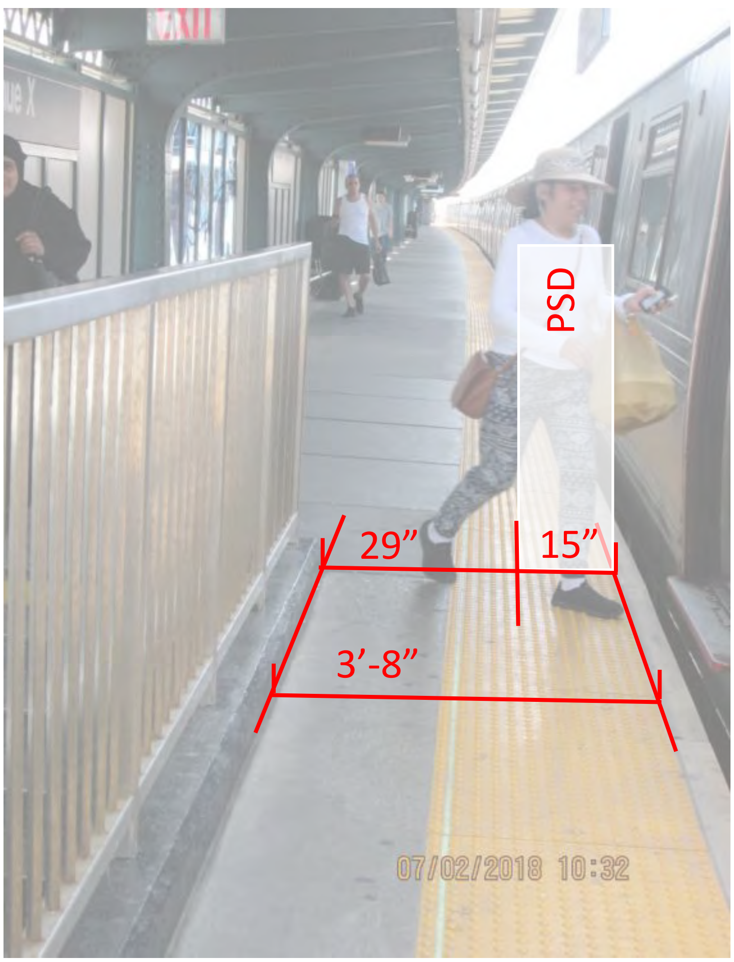

Figure 1– Non-compliant ADA condition – Avenue X Station

Figure 2– Precast T-Beam platform – Avenue X Station

Table of Contents

1.26 MR-253 | Neptune Avenue Station

Summary: *Neptune Avenue Station (MR-253) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, at the centrally located stairs are 3'-10" (46") away from the platform edge. In the implementation of a platform edge barrier, the required 32" width for wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description:

Neptune Avenue Station is an elevated station consisting of a straight center/island platform. The platform is approximately 15'-2" wide. Columns are centered on the width of the platform. Full height PSDs would not be feasible as there is limited canopy cover. The centrally located stairs are close to the platform edge. Adjacent to the stairs, the required 32" width for ADA compliant wheelchair movement would not be met with a platform edge barrier installed.

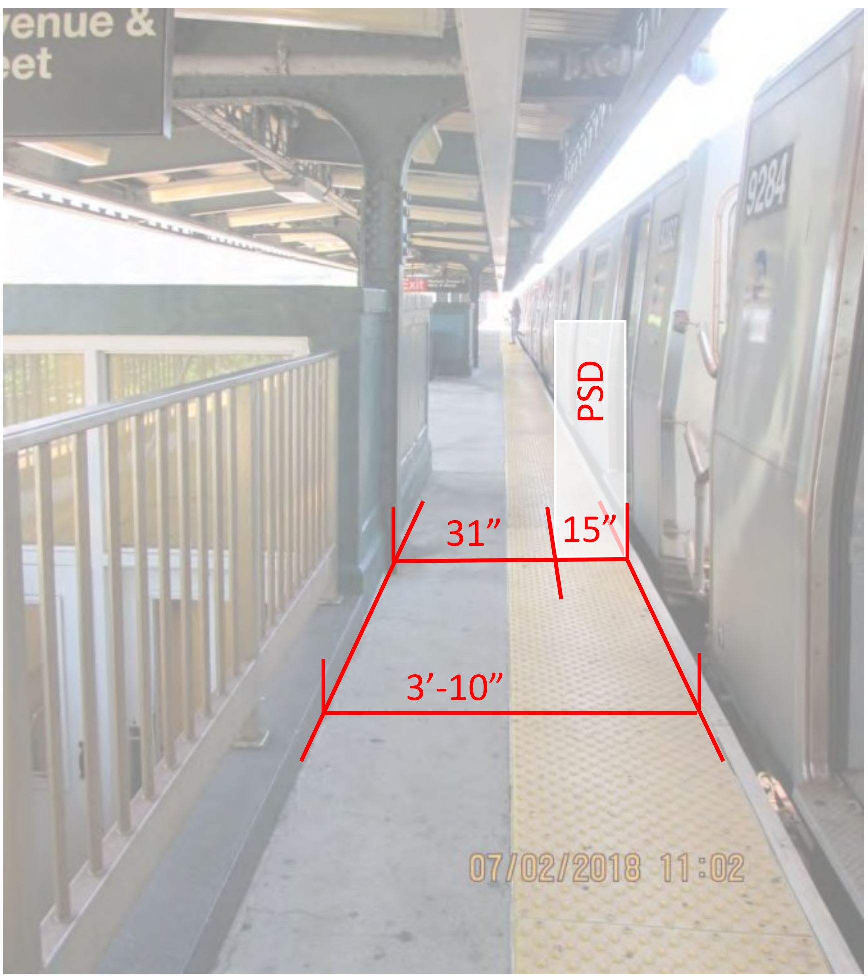

Figure 1– General Platform Condition – Neptune Avenue Station

Figure 2– Precast T-beam Platform – Neptune Avenue Station

1.27 MR-57 | West 8th Street- NY Aquarium Station

Summary: *West 8th Street- NY Aquarium Station (MR-57) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. This issue would occur due to the elevator/escalator room located on the Jamaica-bound platform. A column divides the width between the existing room and the platform edge. This column currently does not allow for wheelchair movement on the Jamaica-bound platform. The 32" minimum requirement for ADA compliant wheelchair movement is currently not met and would be exacerbated in the implementation of a platform edge barrier (see figure 1).*

Description

West 8th Street- NY Aquarium Station is an elevated station with slightly curved side platforms that serve the 'F' and 'Q' trains. The lower platform level serves the 'F' line and the upper platform serves the 'Q' line. The platform structure is cast-in-place concrete. The width of the platform varies from 12'-10" to 5'-2". Columns are typically 2'-3" from the platform edge. Currently, the station does not have an ADA compliant path of travel along the Jamaica-bound platform. The elevator/escalator room is 5'-2" from the platform edge a column segments this width into a 1'-4" and a 2'-4" path of travel. The implementation of a platform edge barrier would further constrain this non-compliant condition.

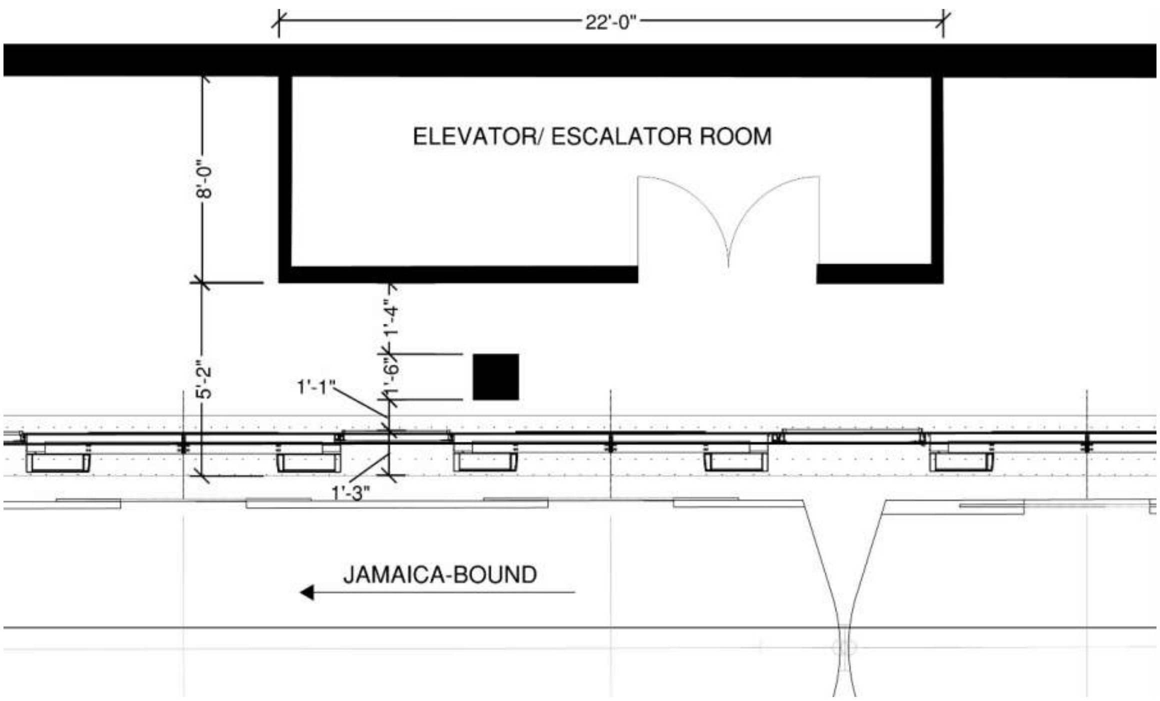

Figure 1 – Non-compliant ADA condition on the Jamaica-bound platform- West 8th St-NY Aquarium

1.28 MR-58 | Coney Island-Stillwell Avenue Station

Summary: *Coney Island-Stillwell Avenue Station (MR-58) is feasible for both APGs and PSDs. This station is the terminus station for the 'N', 'Q', 'D', and 'F' trains. Tracks 5 and 6 serve the F line from a shared center/island platform. The canopy at this station is very tall, and there are no structural members directly above the platform edge. For the installation of a full height PSD system, structural members would have to be attached to existing beams that are approximately 12'-0" high and 5'-0" from the platform edge. One and a half train cars are not covered by a canopy, supplemental overhead structure would be needed in this small along the platform. Platform structural work will be required to support the requirements of an APG and PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Coney Island-Stillwell Avenue Station is an elevated station with four center/island platforms (see figure 1). Each train that is served at this station has a center/island platform for its use only. The 'F' line platform is mostly straight, but tapers at the north-end of the platform. The platform structure is made of cast-in-place concrete. There are two stairs and a centrally located ramp that provide access to the mezzanine level below. Back-of-house elements are situated on the platform ends and in the mezzanine. There are two rows of columns along the length of the platform. These columns are spaced approximately 20'-0" on center with column faces 6'-10" from the platform edge. The platform varies from 20'-0" to 26'-0" wide. One and a half train cars are not covered by the canopy, a supplementary overhead structure would be required in these locations to accommodate a platform edge barrier. See figure 1 for an overall station plan.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As indicated in the summary, there is not structure to mount to directly above the platform edge, some additional framing would be needed in this station (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated on the platform between columns at the center of the platform. The proposed room would measure approximately 16'-0" x 7'-6" (see figure 2). The other lines that are served at this station could use a similar room location on their respective platform (see figure 1)

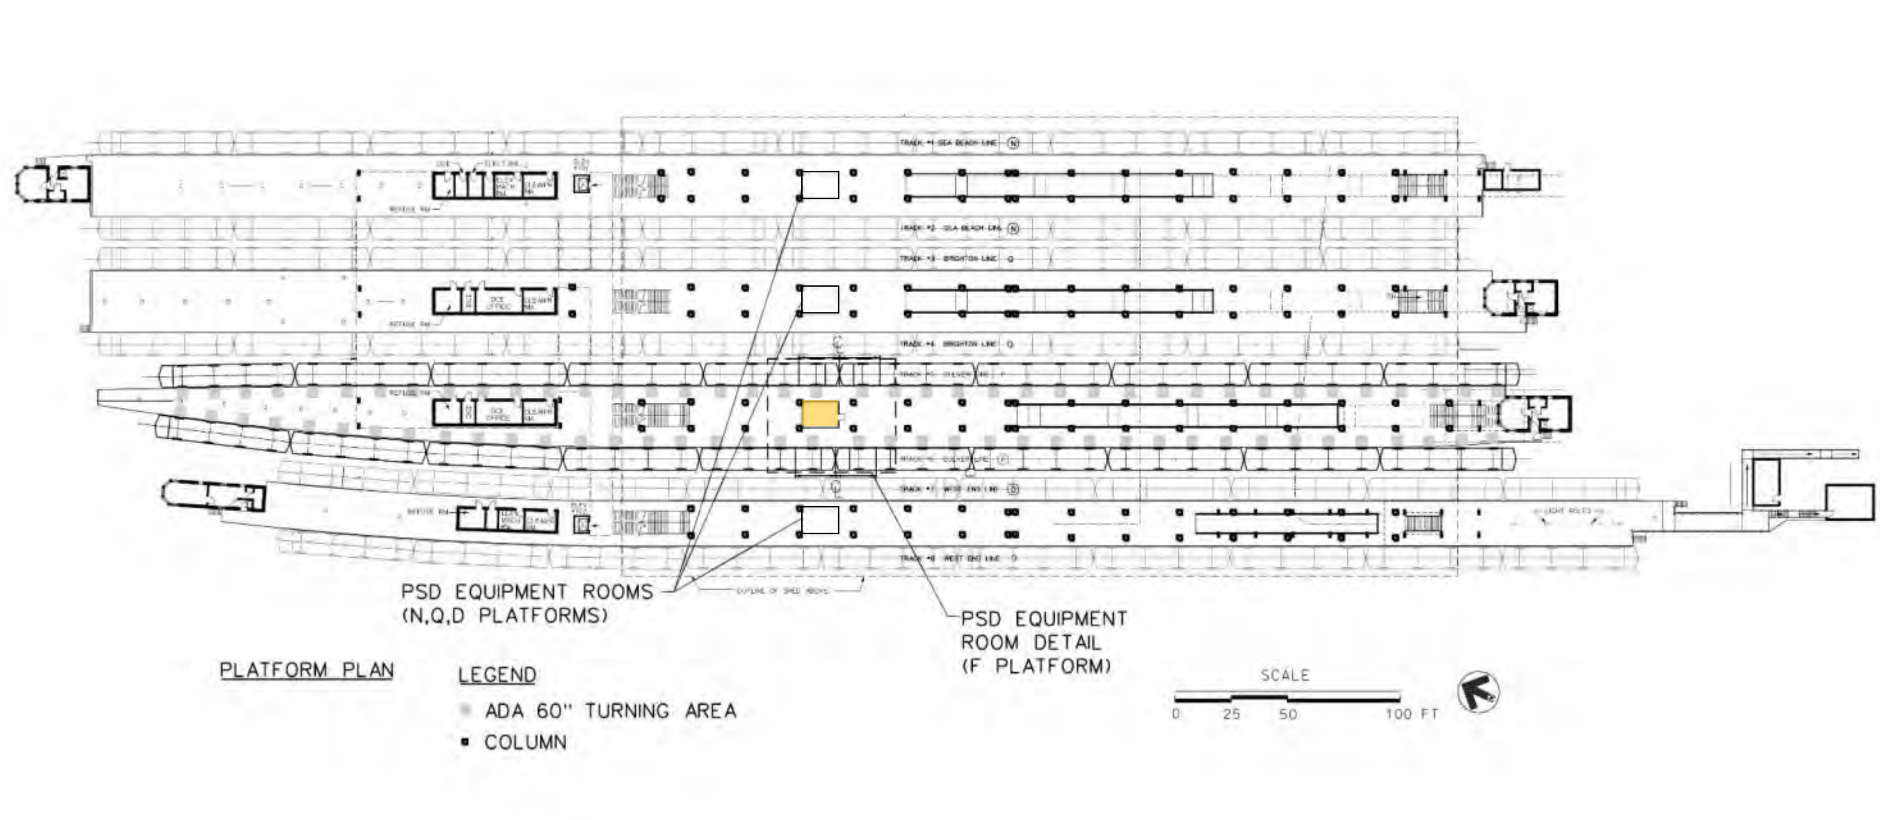

Figure 1 – Station Plan- Coney Island-Stillwell Avenue Station

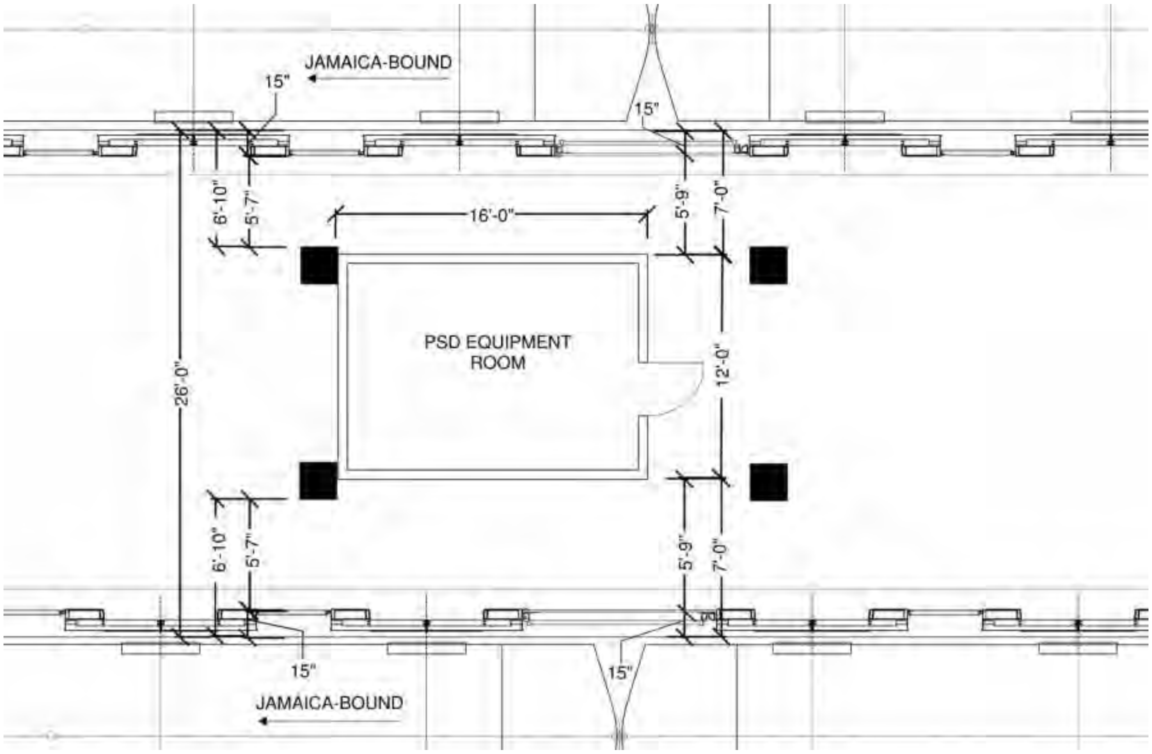

Figure 2 – PSD Equipment Room Detail – Coney Island-Stillwell Avenue Station

Track Layout

Tracks are mostly tangent with the exception of the tapered north-end of the platform. Thus, we are expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions. The 2012 NYCT conditions survey for this station could not be obtained at the time of drafting this report. However it should be noted this station underwent a major rehabilitation in 2005. It can be safely assumed that major reconstruction would be required to implement either a PSD or APG system at this station. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would be required for the installation of an APG system and PSD system. The APG due to its cantilevered configuration and the PSD due to there being no components above it to mount to provide support and stability.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: This station has a lot of natural daylight, however there are also linear fluorescent lights below the beams that run parallel to the platform. These beams are approximately 12'-0" high and 5'-0" from the edge of the platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 and Table 2 please see the Power Capacity Analysis for this station. MRN 058 has adequate capacity to support the implementation of a APG/PSD system only through the reserve system. The Normal EDR possesses inadequate capacity

Station (Reserve)
Power Capacity Analysis

NYCT Station MR Number	58
Station Name	Coney Island Stillwell / Surf Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	112.0
Apparent Power (kVA)	140.0
Station Peak Demand Load, Max Current, (A)	388.9
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	1022
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	179
Is Electrical Service Adequate?	Yes
Notes	This is for Reserve service only. This is based on assumption that each Service is separate.Reserve service has spare capacity. (Normal service has **NO** spare capacity). See Analysis (N) tab.

Table 1. MRN 058 Reserve Capacity Analysis

Station (Normal)
Power Capacity Analysis

NYCT Station MR Number	58
Station Name	Coney Island Stillwell / Surf Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	552.0
Apparent Power (kVA)	690.0
Station Peak Demand Load, Max Current, (A)	1916.7
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	2549
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	This is for Normal service only. Station has (2) separate meter readings (not combined). Normal service has exceeded its service rating. **NO** additional load be connected to this normal service. See Analysis (R) tab.

Table 1. MRN 058 Normal Capacity Analysis

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached

ROM estimate. The total cost for this station (only the F-line platform edges and equipment room) is estimated to be $32.2M to install APGs and $41.0M to install PSDs (See Appendix E).

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

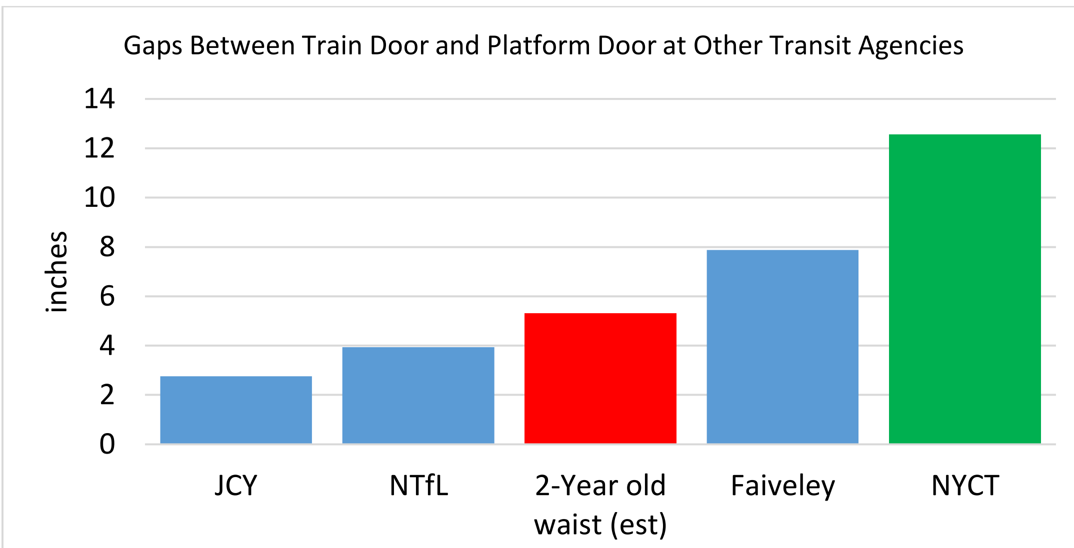

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

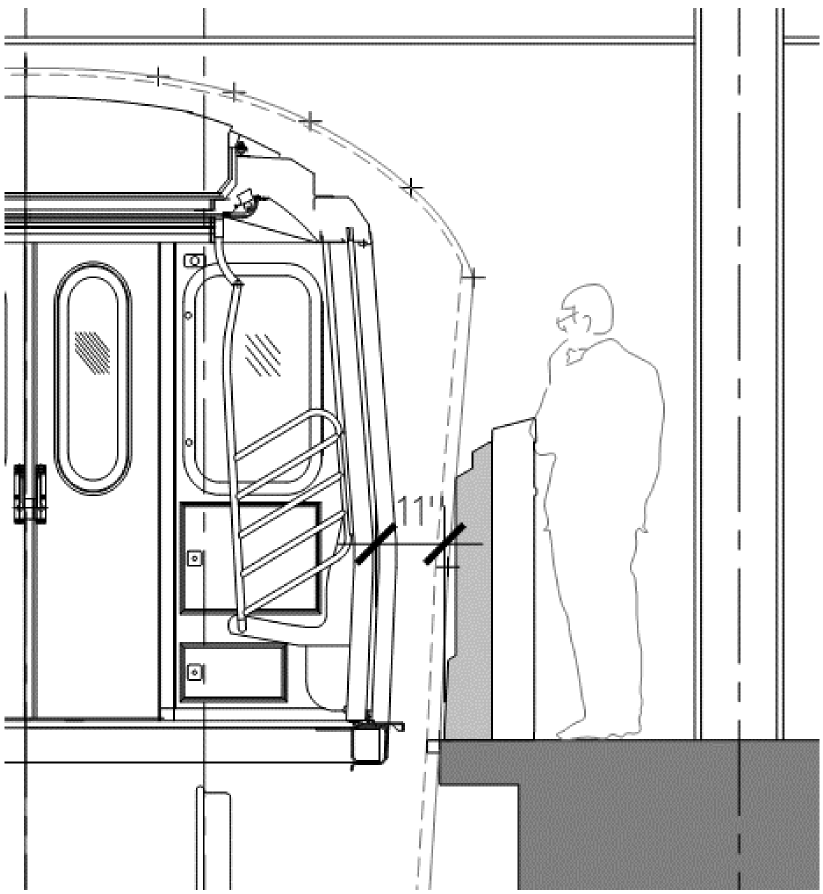

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

304 Turning Space

304.1 General. Turning space shall comply with 304.

304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.

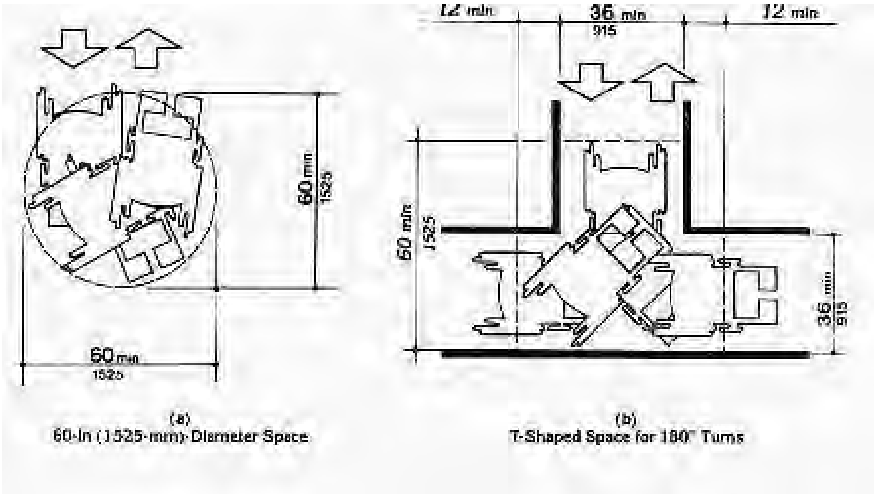
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

> *Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.*

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36” which may be constricted to 32” at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

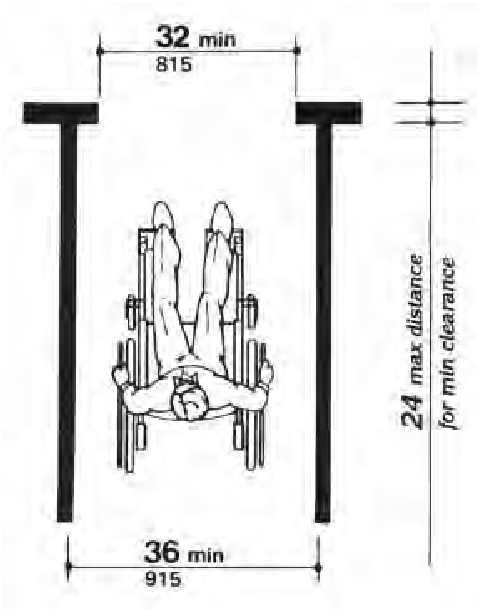


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

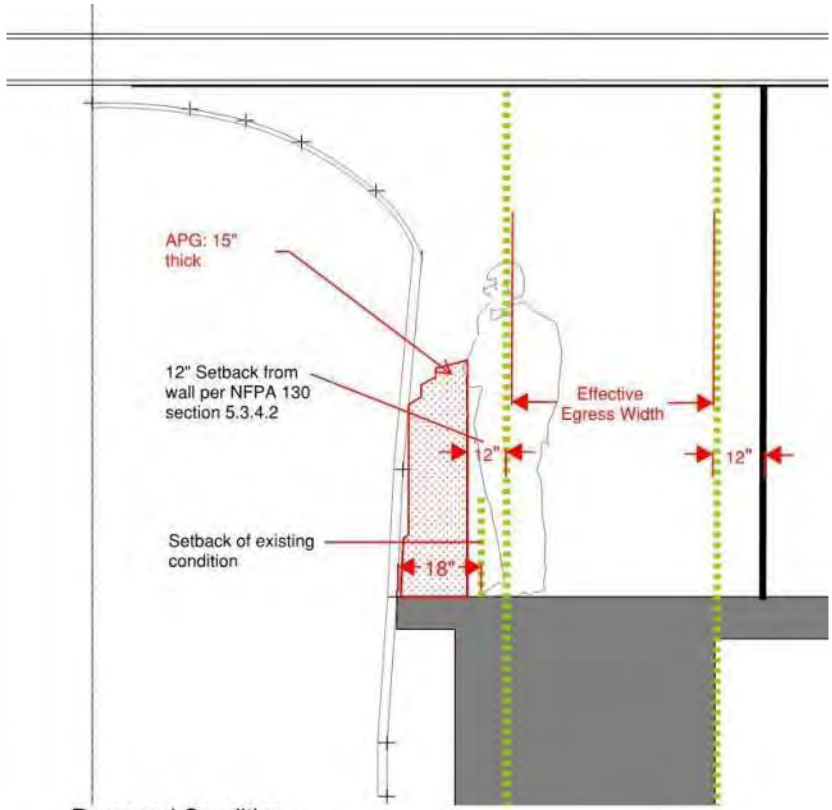
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			$2,961,912		$3,335,028		$732,000
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		$2,961,912		$4,335,028		$12,332,000

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

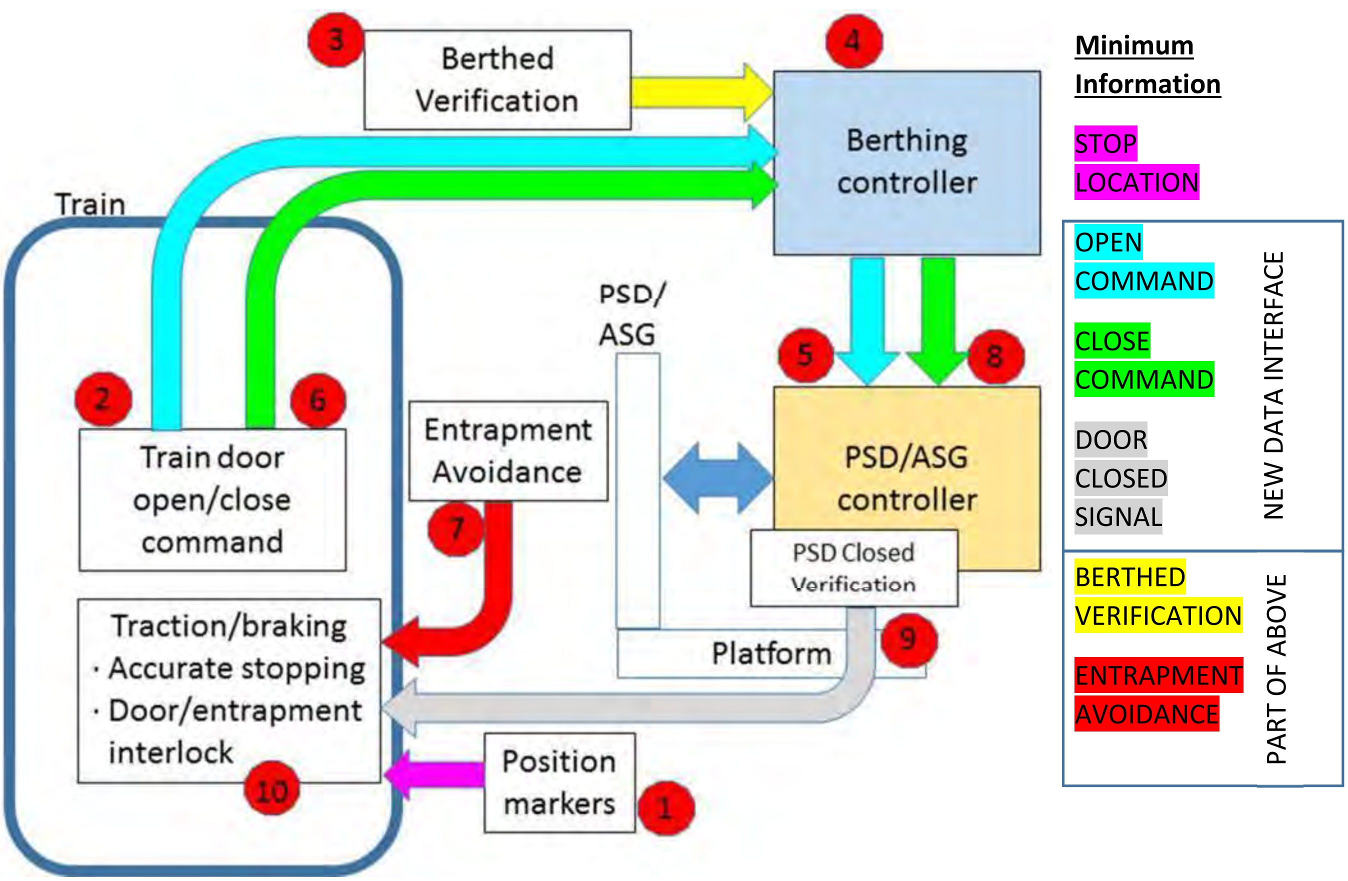
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

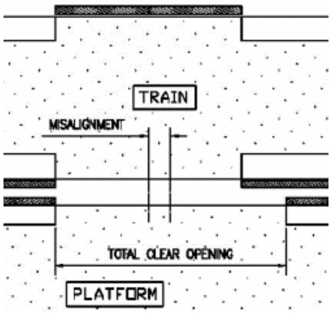
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

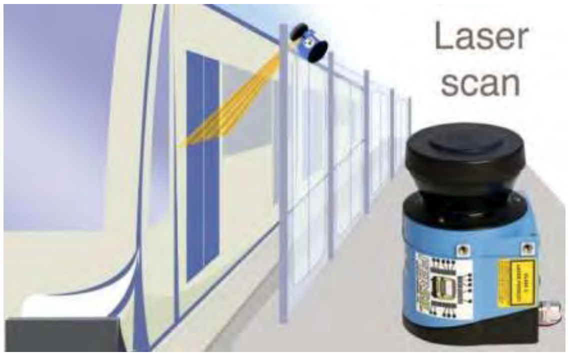
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

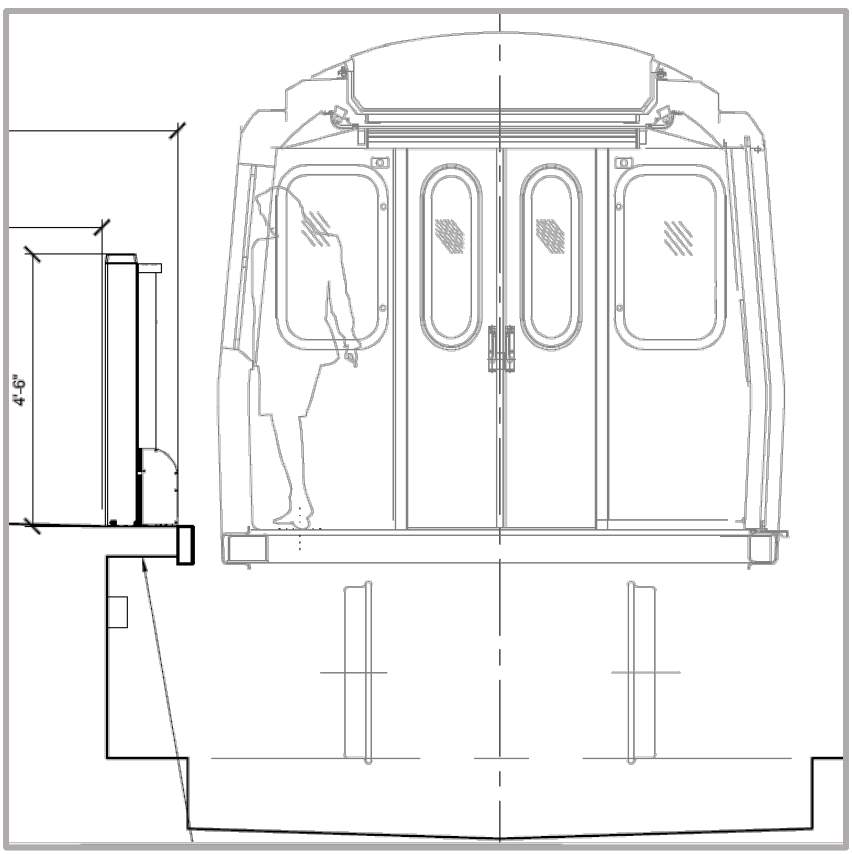


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the “wind” load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1” thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

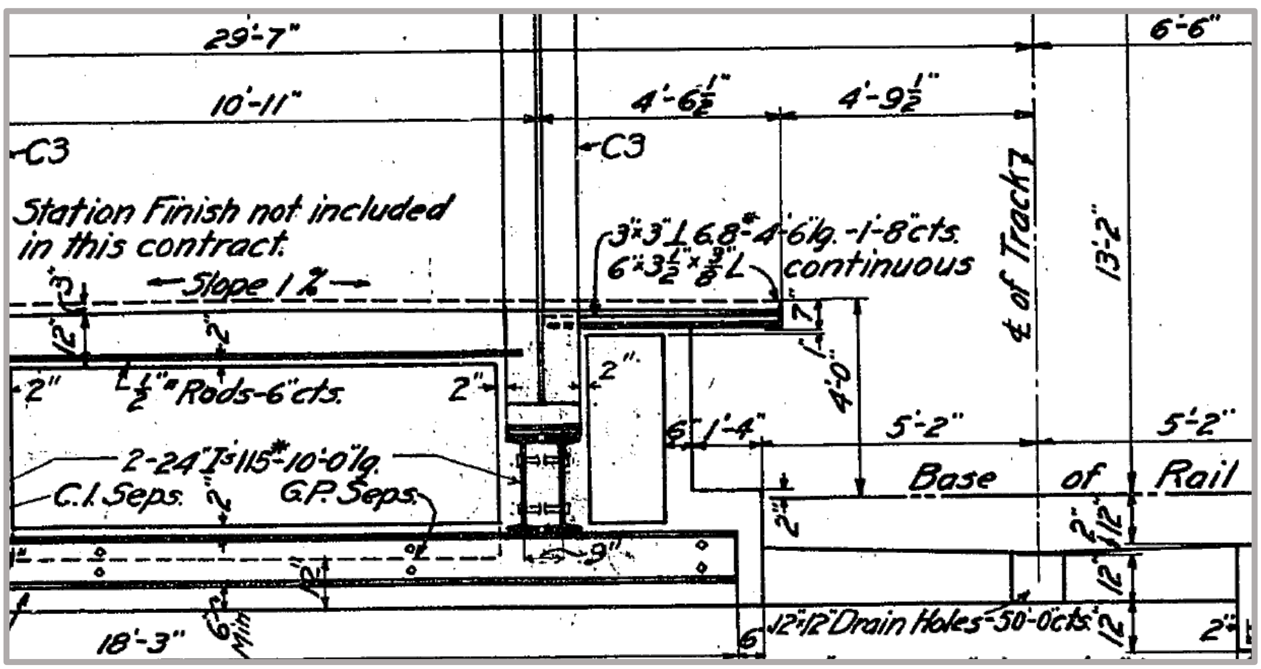

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6” thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1’-2” long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

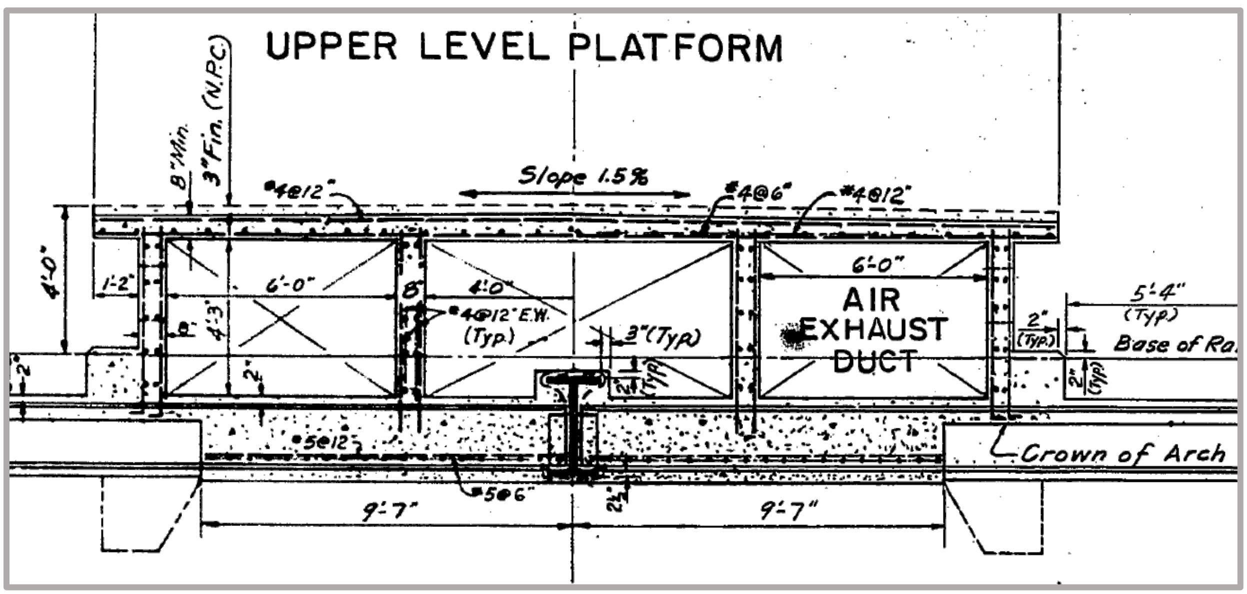

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; “E”, “J”, and “Z” trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

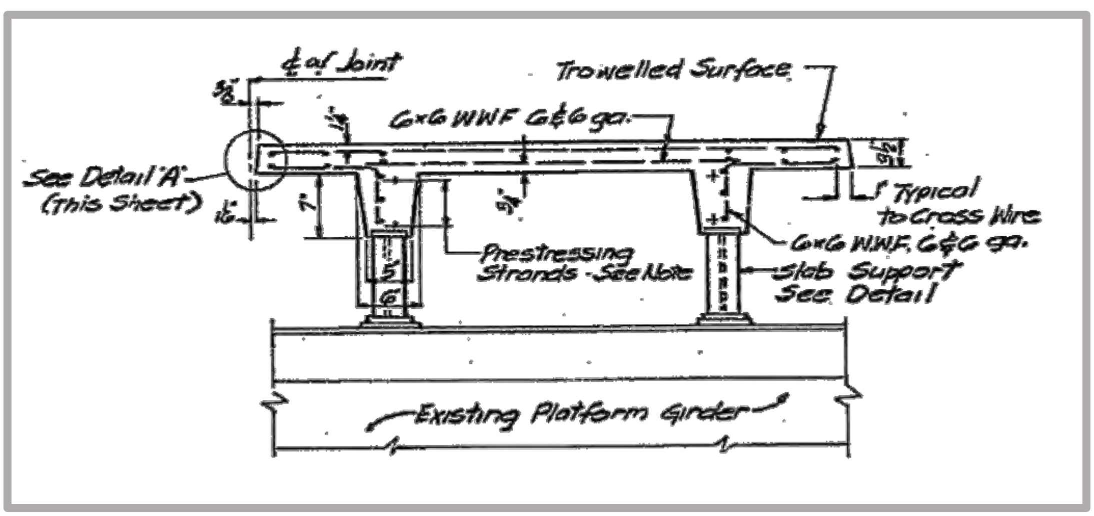

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

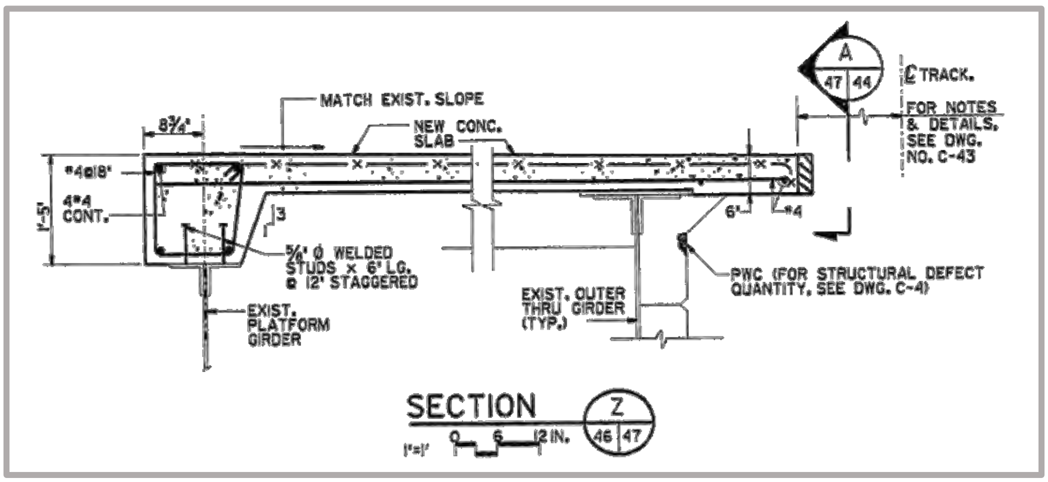

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

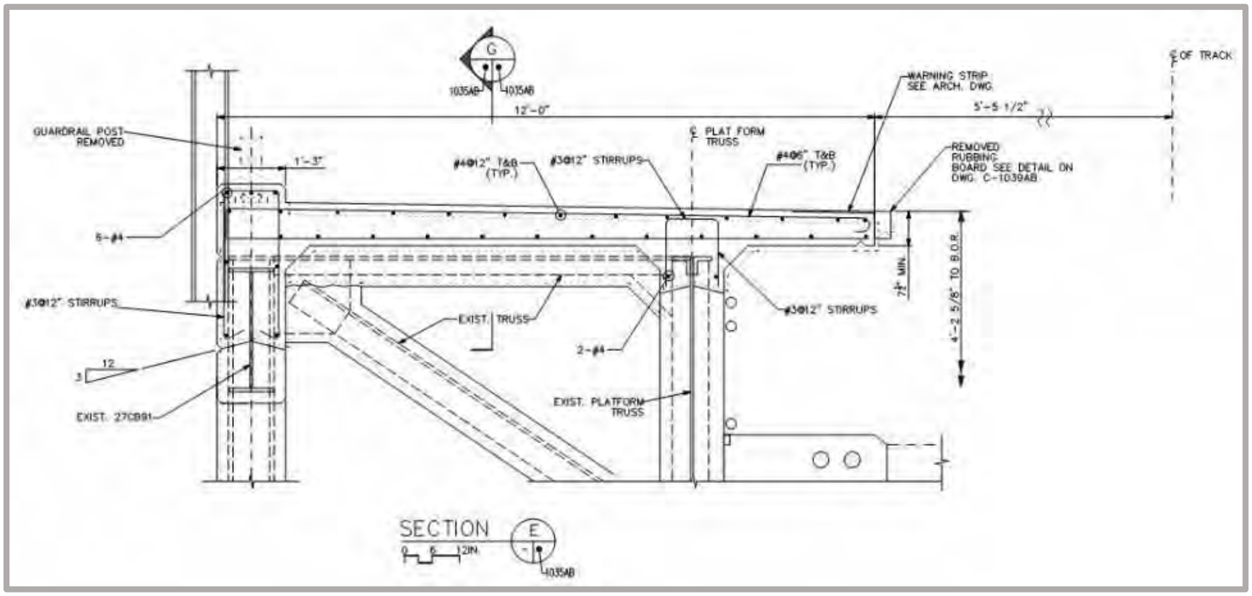

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

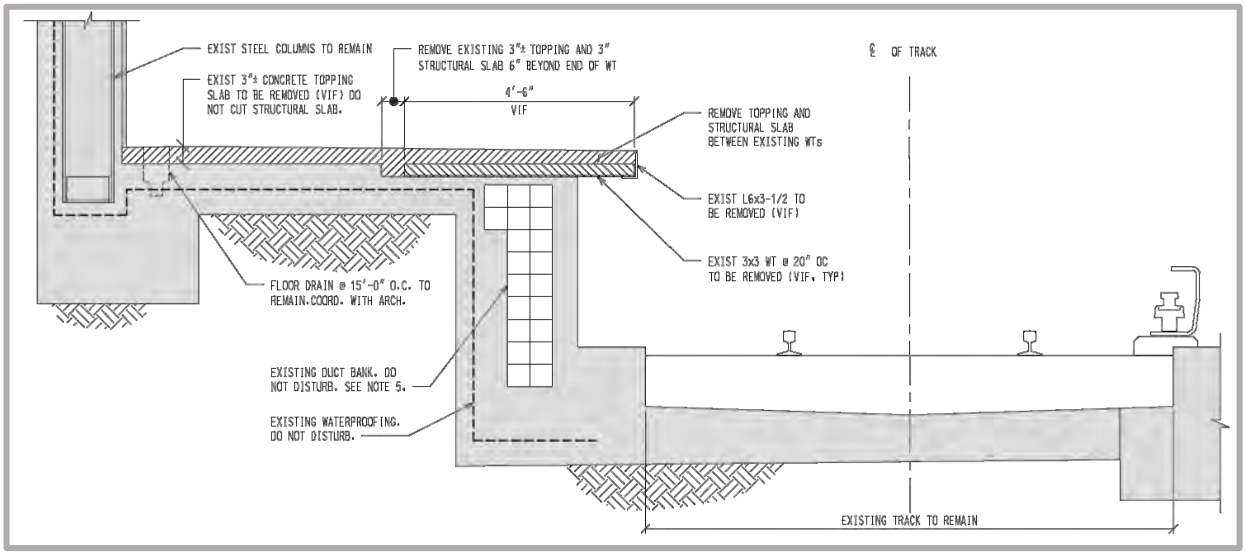

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

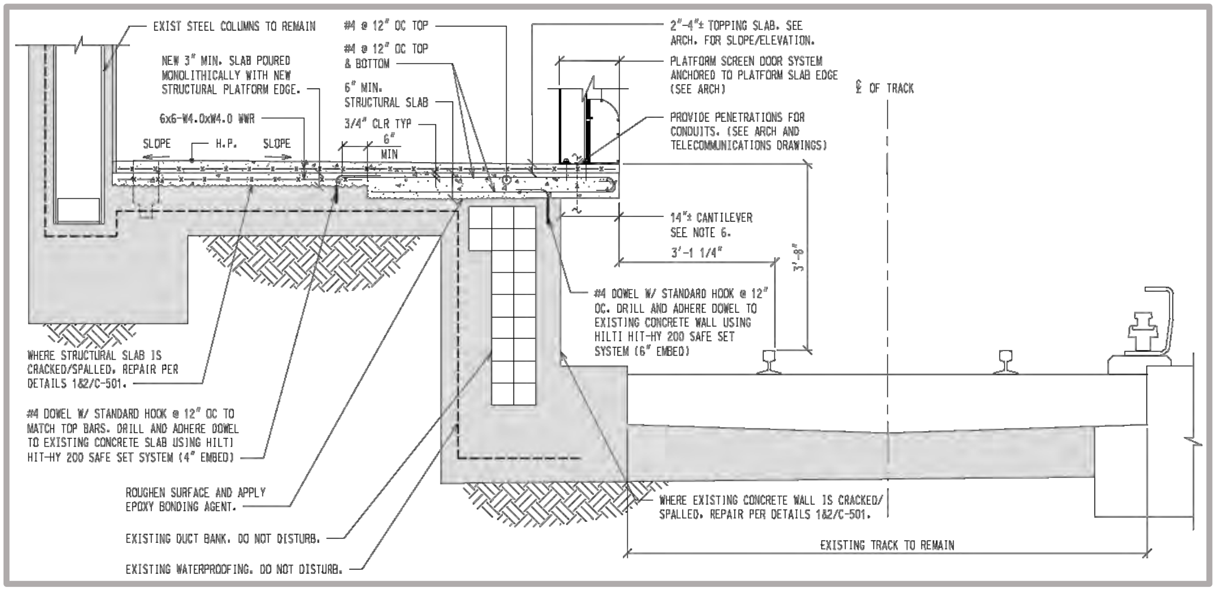

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

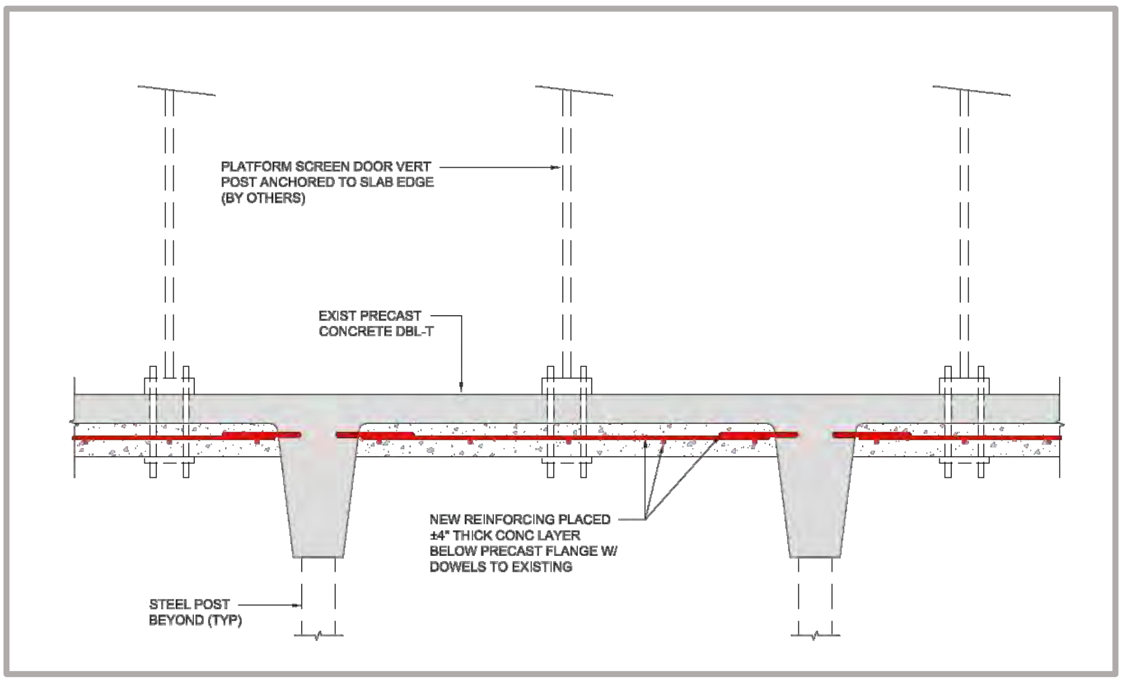

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

MTA/NYCT

October 4, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10” x 10” H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.2 In respect of the PSD option, only platforms that have not been upgraded in the recent past (assuming over the past two decades) will require platform edge replacement.
2.3 There are no special security requirements made necessary by installation of the APG system
2.4 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.5 This estimate does not provide for the replacement of Platform Edge Lighting
2.6 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

MTA/NYCT

October 4, 2018

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 *Given the limited time available, no drawings were developed to support this estimate.*

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: 21ST STREET - QUEENSBRIDGE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	607	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,222**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,222	LF	7	8,554
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,110	SF	12	73,320
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	123	CY	2,500	307,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,224	EA	25	30,600
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,224	EA	25	30,600
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,222	LF	95	116,090
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,222	LF	15	18,330
26	Remove existing platform tiles	1,222	LF	12	14,664
27	Sawcut existing topping concrete at perimeter of removal area	1,222	LF	5	6,110
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,332	SF	8	58,656
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 12'-6" wide strip	572	SF	8	4,576
30	New Work				
31	New concrete topping to match existing	1,222	SF	15	18,330
32	New concrete topping at ADA boarding area to match existing	572	SF	15	8,580

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: LEXINGTON AVE - 63RD ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	615	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,230	LF	7	8,610
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,230	LF	95	116,850
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
26	Remove existing platform tiles	1,230	LF	12	14,760
27	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 21'-6" wide strip at ADA boarding area	418	SF	8	3,344
30	New Work				
31	New concrete topping to match existing	1,230	SF	15	18,450
32	New concrete topping at ADA boarding area to match existing	418	SF	15	6,270

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: STILLWELL AVE - CONEY ISLAND

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [TRACK 5] =	640	LF		
5	LENGTH OF THE PLATFORM EDGE [TRACK 6] =	640	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,280**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,280	LF	7	8,960
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,400	SF	12	76,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	129	CY	2,500	322,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,282	EA	25	32,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,282	EA	25	32,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,280	LF	95	121,600
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,280	LF	15	19,200
26	Remove existing platform tiles	1,280	LF	12	15,360
27	Sawcut existing topping concrete at perimeter of removal area	1,280	LF	5	6,400
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,680	SF	8	61,440
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 27'-0" wide strip at ADA boarding area	660	SF	8	5,280
30	New Work				
31	New concrete topping to match existing	1,280	SF	15	19,200
32	New concrete topping at ADA boarding area to match existing	660	SF	15	9,900

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘B’ SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: June 3, 2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 37 newly evaluated stations, 31 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the B-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 16% of the 'B' Line Stations. Total implementation cost would be \$189.4M for APGs and \$242.7M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of \$931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 6 feasible stations, the aggregate annual maintenance cost would be \$5.6M.

Summary Table

(16% Feasible 6/37)

1.0 Station Assessments

1.01 – MR 026 | Dekalb Avenue Station

Summary: *Dekalb Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

Dekalb Ave Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. The platform columns are spaced 10'-10" on center, and column faces typically measure 3'-8" from the platform edge. The platform width is 15'-8" throughout. At the platform staircases, the columns flanking the stairs measure 3'-8" from the platform edge and are touching the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 44" to 29" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

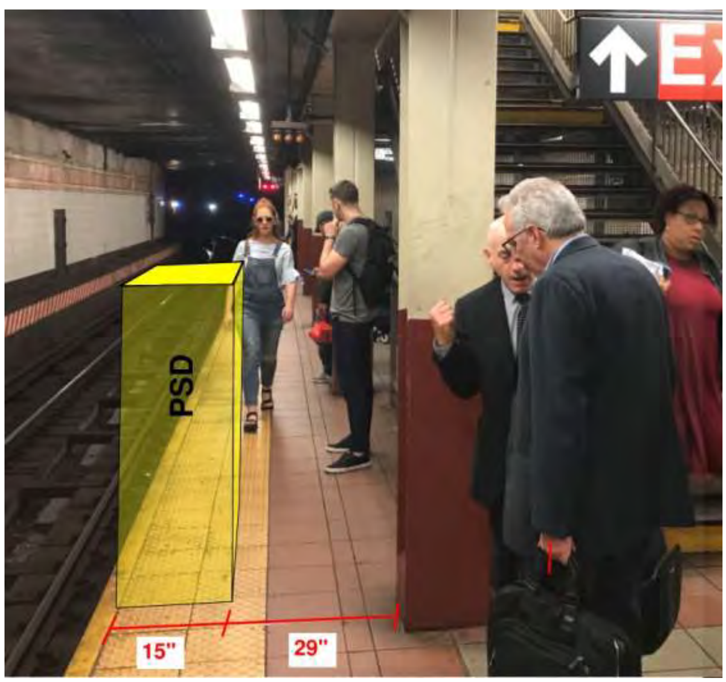

Figure 1 *– Non-Compliant ADA condition Dekalb Avenue Station*

1.02 –MR 040 | Atlantic Avenue Barclay Center Station

Summary: *Atlantic Avenue Barclay Center Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 8" (see figure 1).*

Description

The Atlantic Avenue Barclay Center Station is a below-grade station with one center / island platform. The platform structure is cast-in-place concrete. There are two rows of columns which lie 23" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum pinch point width of 32". The remaining 8" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

Figure 1 *– Non-compliant ADA condition*
Atlantic Avenue Barclay Center Station

1.03 – MR 041 | 7th Avenue Flatbush Station

Summary: *7th Avenue Flatbush Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would prohibit the installation of a 15"-wide PSD system.*

Description:

7th Avenue Flatbush Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1 –** Column 12" from the edge*
7th Avenue Flatbush Avenue Station

1.04 – MR 042 | Prospect Park

Summary: *Prospect Park Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Prospect Park Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms at the north end is 3'-10". The implementation of a platform edge barrier would reduce this width below the required minimum corridor width of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

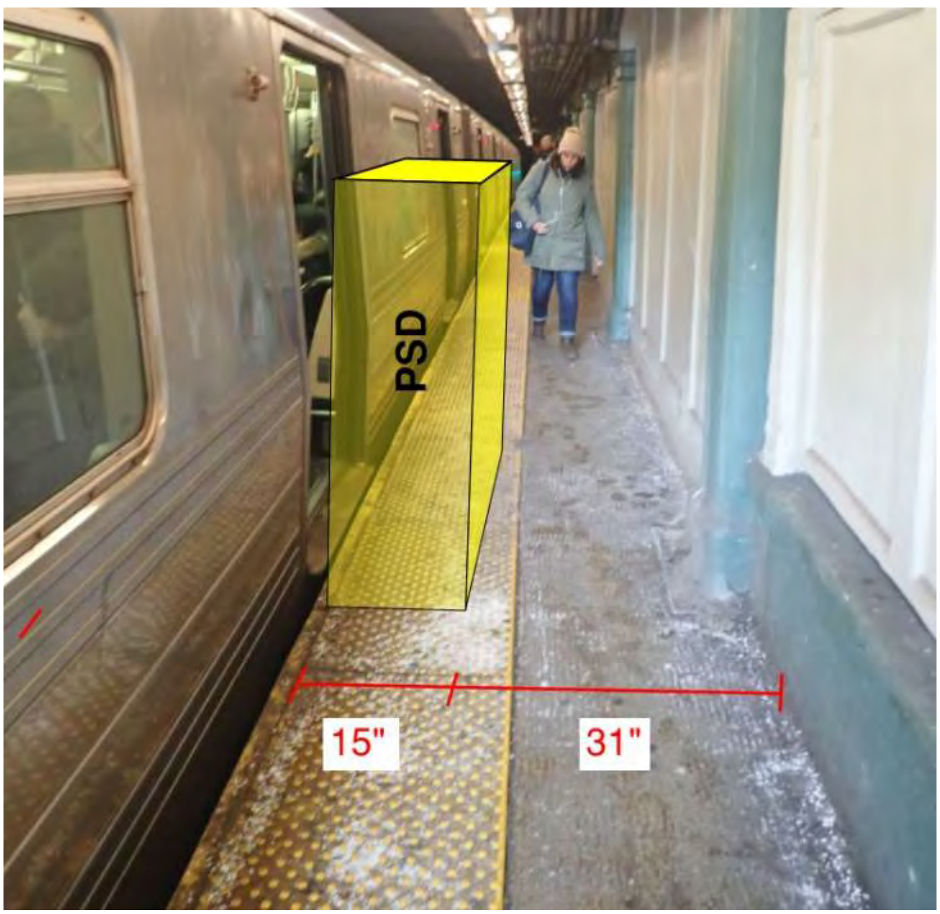

Figure 1 *– Non-compliant ADA condition*
Prospect Park Station

1.05 – MR 044 | Church Avenue Station

Summary: *Church Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 15" (see figure 1).*

Description

The Church Avenue Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The corridor width adjacent to the station department room is 30". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Church Avenue

1.06 – MR 047 | Newkirk Plaza Station

Summary: *Newkirk Plaza Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

The Newkirk Plaza Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The pinch point width at platform columns at staircases is 28". The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 13" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

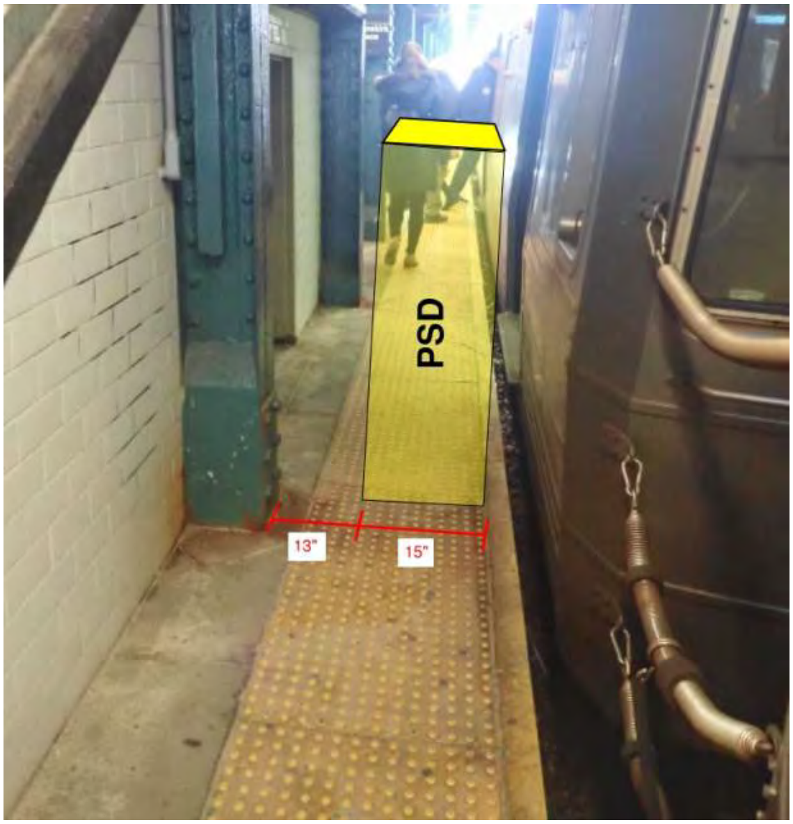

Figure 1 – *Area of ADA non-compliance*
Newkirk Plaza Station

1.07 – MR 051 | Kings Highway Station

Summary: *Kings Highway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

The Kings Highway Station is an embankment station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 15'-0". At the elevator, the clearance is 3'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

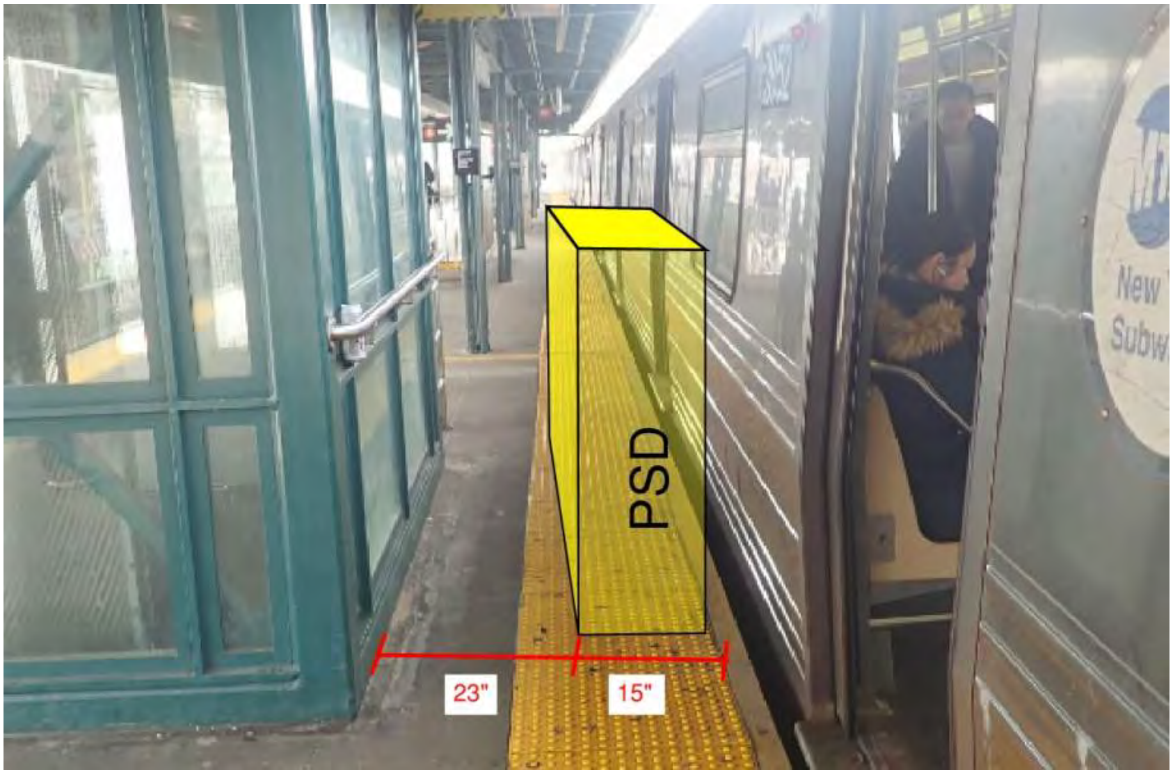

Figure 1 – *Area of ADA non-compliance*
Kings Highway Station

1.08 – MR 054 | Sheepshead Bay Station

Summary: *Sheepshead Bay Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Sheepshead Bay Station is an elevated station with two curved center / island platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-6". At the stairs, the clearance is 3'-8". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Sheepshead Bay Station

1.09 – MR 055 | Brighton Beach Station

Summary: *Brighton Beach Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Brighton Beach Station is an elevated station with two curved center / island platforms. The platform structures are cast-in-place concrete. The platforms are approximately 15'-6" in width. At the four stairways, the clearance is 3'-8" from edge of platform. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

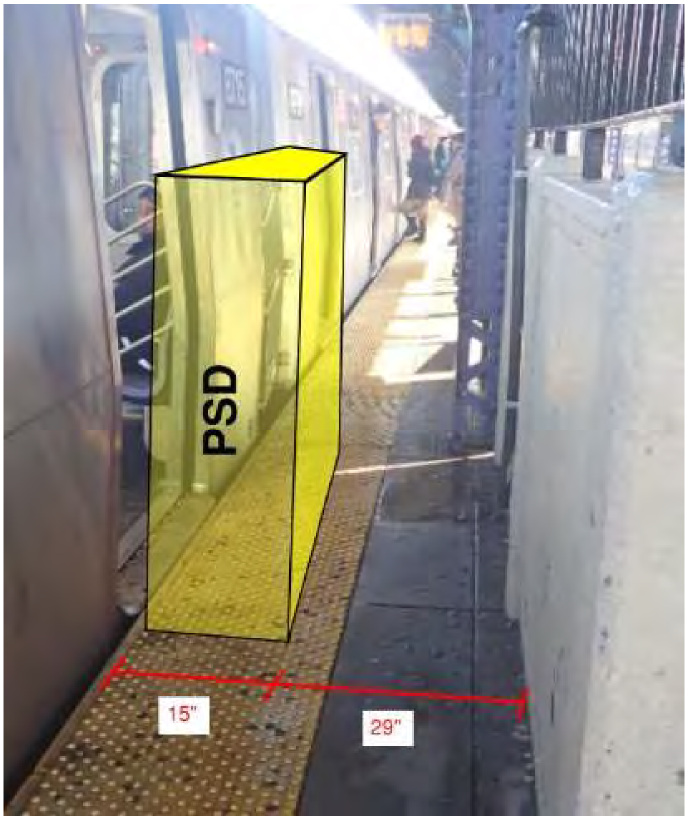

Figure 1 – *Area of ADA non-compliance*
Brighton Beach Station

1.10 – MR 151 | 145th Street St. Nicholas Avenue Station

Summary: *145th Street St. Nicholas Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

The 145th Street St. Nicholas Avenue Station is a below grade station with two straight center / island platforms at each level of this two-level station. The B-train service utilizes the lower level. The platform structures are cast-in-place concrete. The width of the platforms at the platform staircases is 4'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA dimension*
145th Street Station

1.11– MR 152 | 135th Street Station

Summary: *135th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 135th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the edges of the platform and measure 3'-4" from the platform edge. The platform width varies from approximately 7'-0" to 14'-8". On the southbound and northbound platforms there is a ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the southern control area at the end of the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would at a minimum be required for the installation of an APG system.

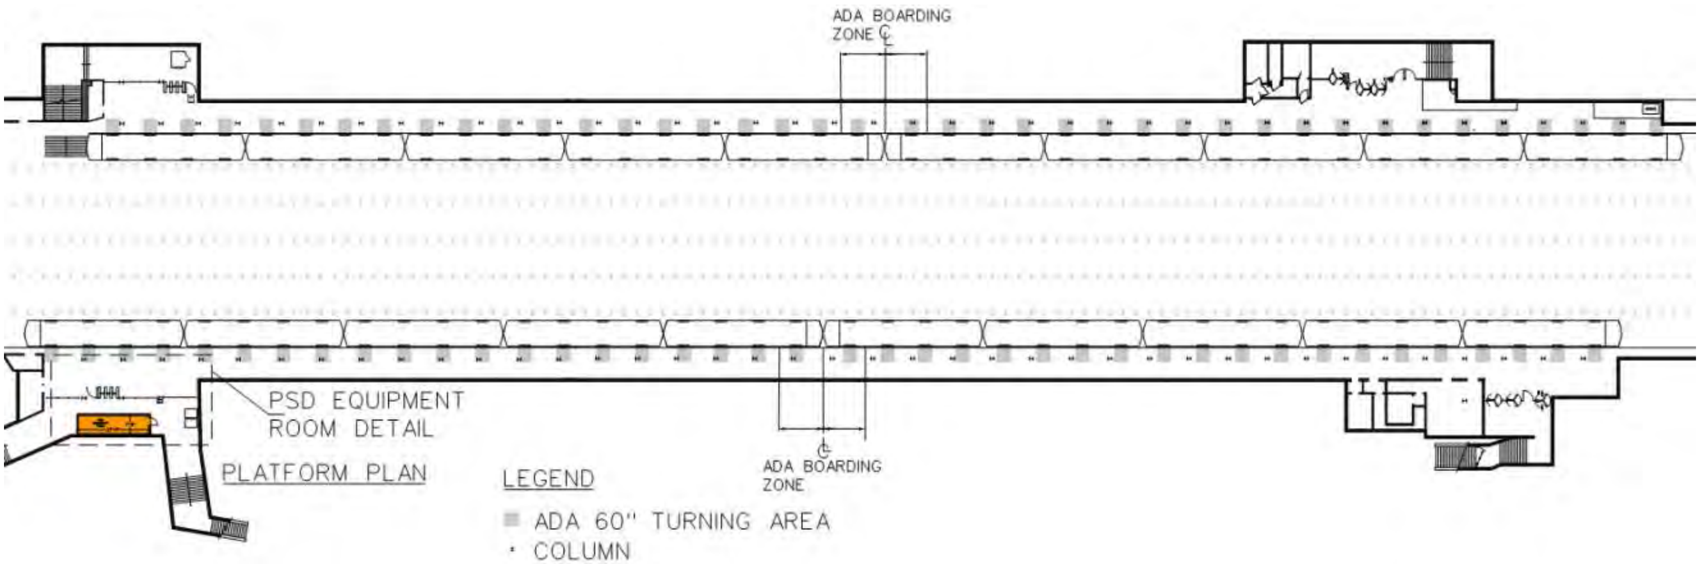

Figure 1 *– Overall Station Plan*
135th Street Station

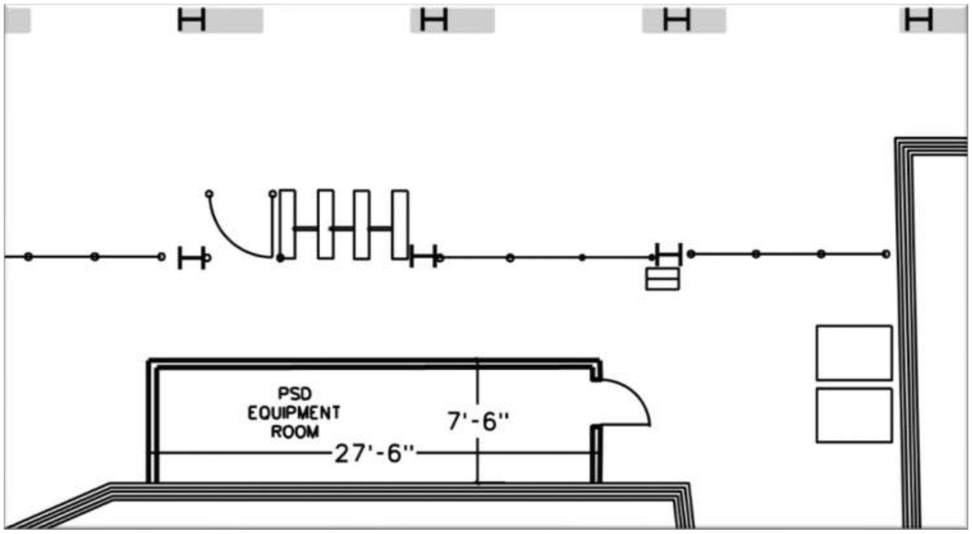

Figure 2 *– PSD Equipment Room 1 Detail*
135th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	135th Street

None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $30.6M to install APGs and $39.4M to install PSDs (See Appendix E).

Figure 3 – Typical platform view with signal light
135th Street Station

1.12 – MR 153 | 125th Street St. Nicholas Ave. Station

Summary: *125th Street St. Nicholas Ave. Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

125th Street St. Nicholas Ave. Station is a below-grade station with two center / island platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the center of each platform and measure 8'-4" from the platform edge. The platform widths vary from approximately 17'-4" to 17'-10". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the center of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $41.5M to install PSDs (See Appendix E)

1.13 – MR 154 | 116th Street / 8th Ave Station

Summary: *116th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 19" (see figure 1).*

Description

116th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 11'-8" throughout. The width at the south end of the northbound platform is 34". The implementation of a platform edge barrier would reduce this already noncompliant width below the required minimum corridor requirement of 36". The remaining 19" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
116th Street Station

1.14– MR 155 | 110th St. Cathedral Pkwy Station

Summary: *110th St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

110th St. Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-0' to 11'-8". The implementation of a platform edge barrier would reduce this lesser (already noncompliant) width below the required minimum corridor requirement of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

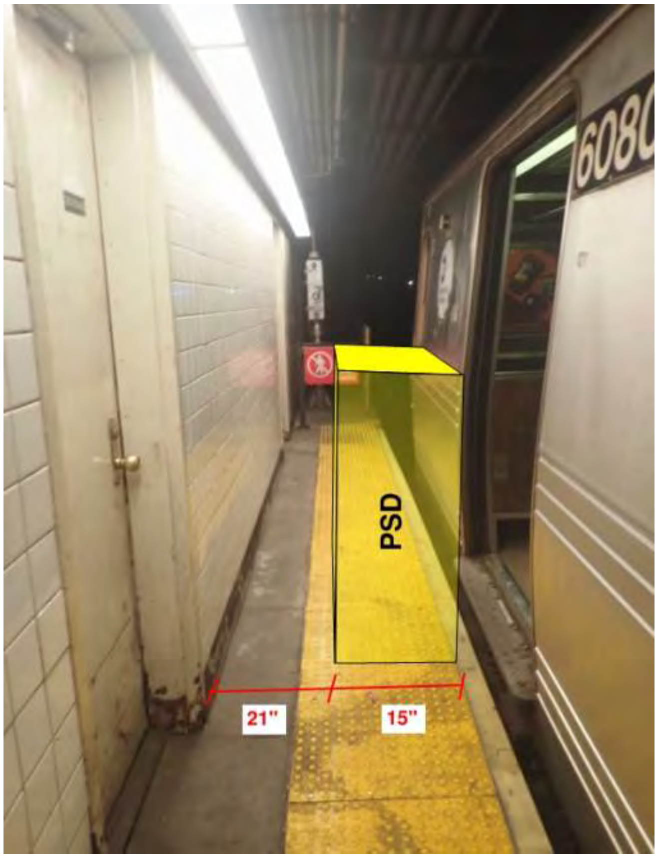

Figure 1 – Non-Compliant ADA condition
110th Street

1.15– MR 156 | 103rd Street Station

Summary: *103rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

103rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 2'-4' to 10'-0". The implementation of a platform edge barrier would reduce this lesser (already noncompliant) width, below the required minimum corridor requirement of 36". The remaining 13" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
103rd Street

1.16 – MR 157 | 96th Street Station

Summary: *96th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 96th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the center of each platform and measure 3'-4" from the platform edge. The platform widths vary from approximately 11'-8" to 12'-0". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the northern control area at the end of the northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would at a minimum be required for the installation of an APG system.

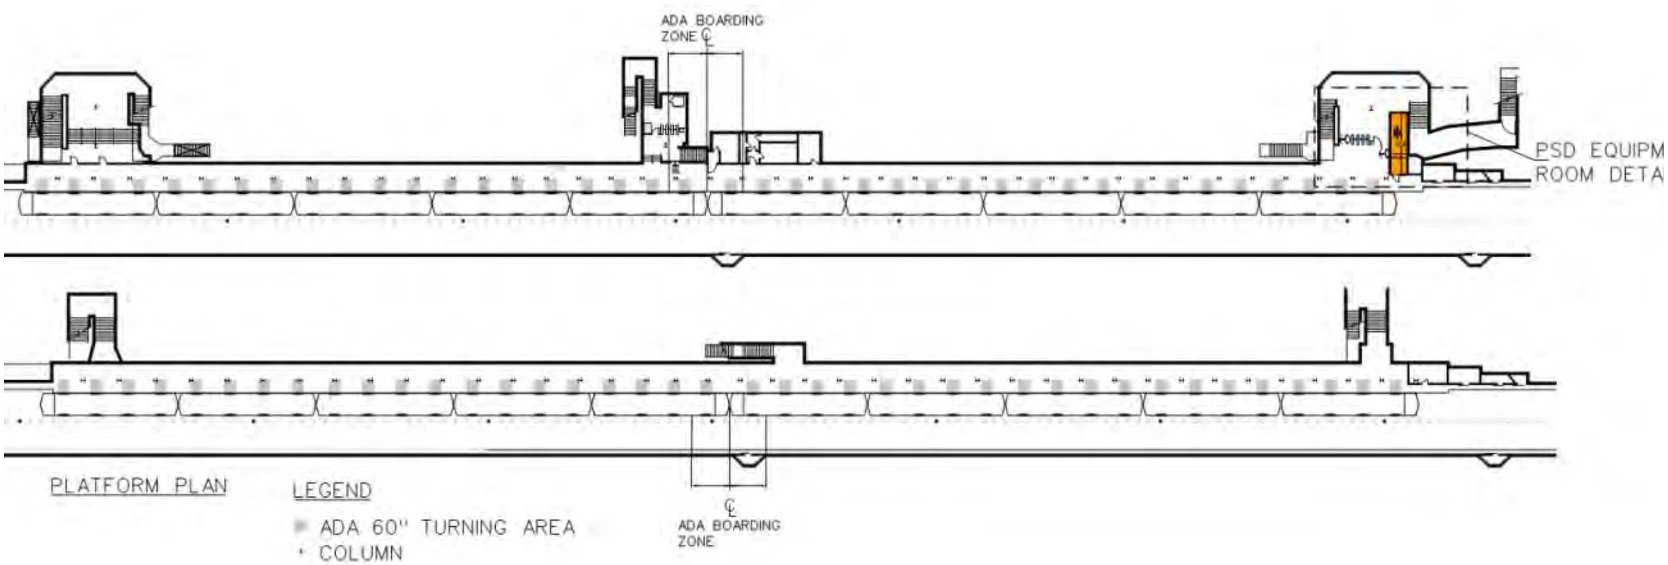

Figure 1 *– Overall plan*
96th Street Station

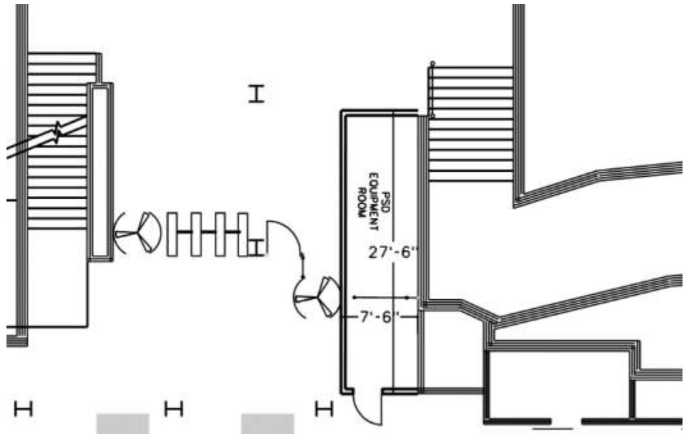

***Figure 2** – PSD Equipment Room Detail*
96th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	96th Street
Peak Demand Load from ConEd Report, (kW)	47.2 (combined)
Apparent Power (kVA)	59.0
Station Peak Demand Load, Max Current, (A)	163.9
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	358
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	442
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the field survey(photos) having 800A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve. 1 line diagram provided does not have service rating and is incomplete.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.8M to install APGs and $38.7M to install PSDs (See Appendix E)

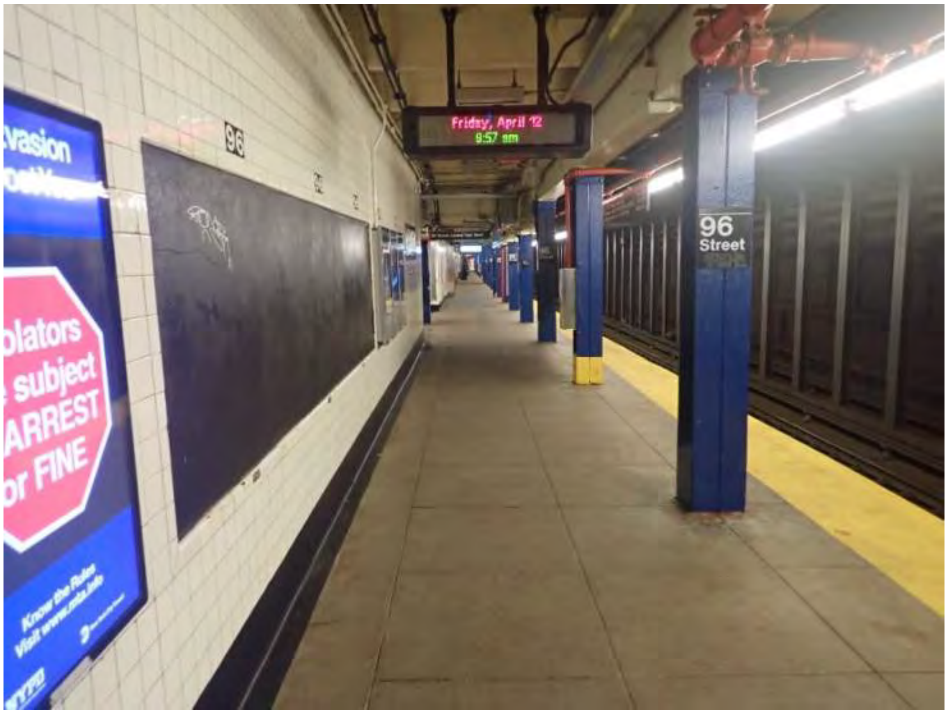

***Figure 3** – General platform view*
96th Street Station

1.17 – MR 158 | 86th Street Station

Summary: *86th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

86th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-0' to 11'-8". The implementation of a platform edge barrier would reduce this lesser width below the required minimum corridor requirement of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
86th St Station

1.18 – MR 159 | 81st St. Museum of Natural History

***Summary:** 81st St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

81st St. Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-10". The implementation of a platform edge barrier would reduce this lesser width below the required minimum corridor requirement of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
81st St. Station

1.19 – MR 160 | 72nd Street Station

Summary *72nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 4'-8" (see figure 1).*

Description

72nd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-8' to 11'-10". The north end of the southbound platform in the photo below, is 4'-8" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

Figure 1 – Non-Compliant ADA condition
72nd Street Station

1.20 – MR 161 | 59th Street Columbus Circle Station

Summary: *59th Street Columbus Circle Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

59th Street Columbus Circle Station is a below-grade station consisting of two center / island platforms (there is a third island platform which is closed to the public). The platform widths vary from approximately 10'-8" – 29'-0". The platforms are mildly curved with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-0" from the platform edge and 2'-2" from the staircase (see figure 1 for reference).The implementation of a platform edge barrier would reduce the currently compliant width of 36" to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

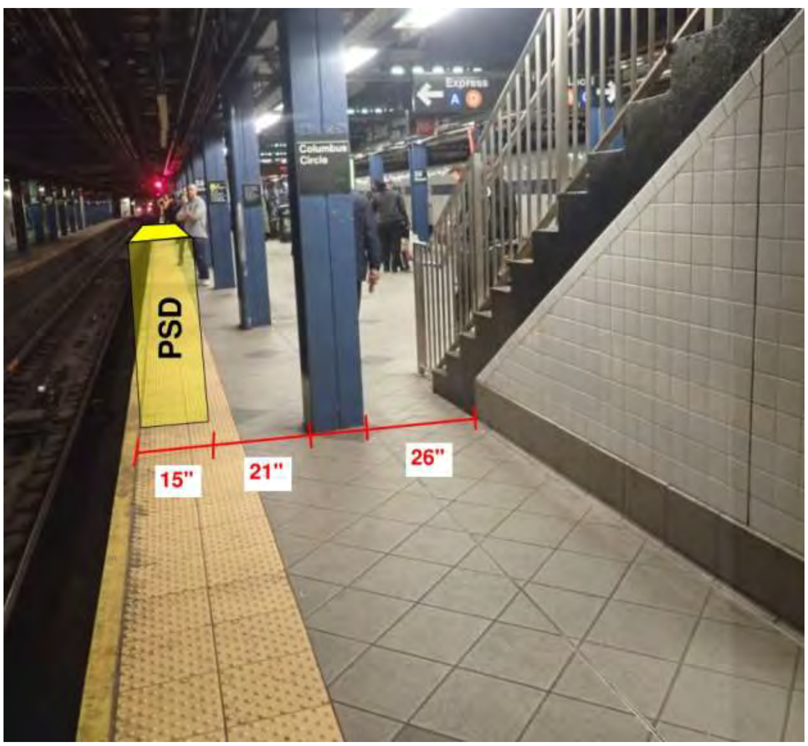

Figure 1 *–platform*
59th Street Columbus Circle Station

1.21 – MR 211 | Bedford Park Blvd Station

Summary: *Bedford Park Blvd Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Bedford Park Blvd. Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 19'-0" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 26" from the staircase (see figure 1 for reference).The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
Bedford Park Blvd Station

1.22 – MR 212 | Kingsbridge Road Station

Summary: *Kingsbridge Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Kingsbridge Road Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 19'-6" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-8" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
Kingsbridge Road Station

1.23 – MR 213 | Fordham Road Station

Summary: *Fordham Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Fordham Road Station is a below-grade station consisting of one center / island platform. The platform width varies from approximately 10'-8" to 54'-8" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-10" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
Fordham Road Station

1.24 – MR 214 | 182nd-183rd St Station.

***Summary:** 182nd-183rd St Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

182nd-183rd St Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-8" throughout. The platforms are straight with one row of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 2'-0" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

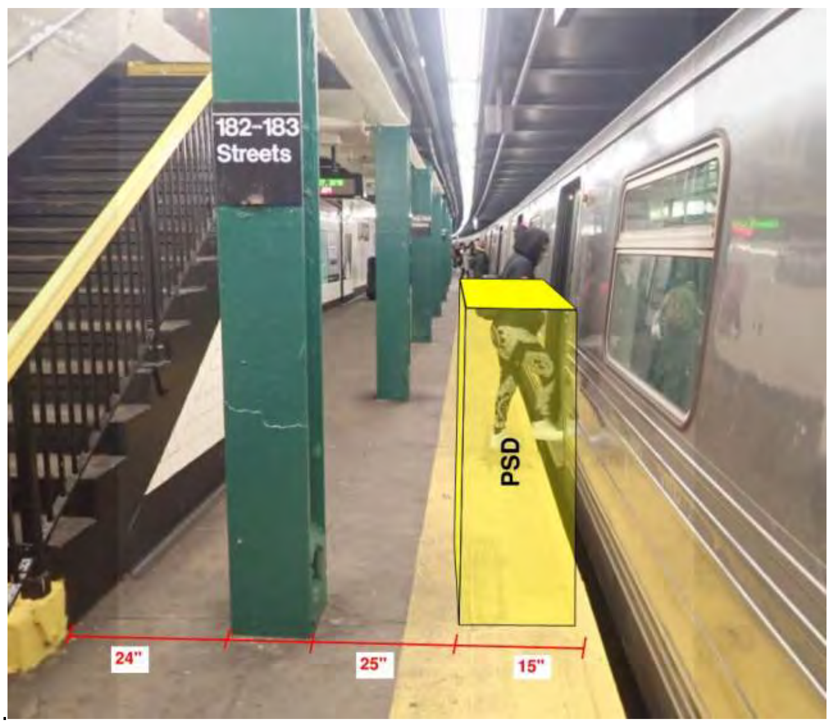

***Figure 1** – Non-Compliant ADA condition*
182nd-183rd Sts Station

1.25 – MR 215 | Tremont Avenue Station

Summary: *Tremont Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

Tremont Avenue Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 22'-0" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-4" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Tremont Avenue

1.26 – MR 216 | 174th-175th St Station

Summary: *174th-175th St Station is feasible for both APGs and PSDs. There are two ceiling mounted monitors located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 174th-175th St Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are columns evenly distributed along the platform edge measuring 3'-6" from the platform edge. The platform widths vary from approximately 10'-8" to 21'-0". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 6'-8". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the edge of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.9M to install APGs and $40.1M to install PSDs (See Appendix E)

1.29 – MR 219 | 161st Street Yankee Stadium Station

***Summary:** 161st Street Yankee Stadium Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met on the northbound platform as the remaining width would be 27" (see figure 1).*

Description

161st Street Yankee Stadium Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-4" throughout. The platforms are straight with one rows of columns approximately 3'-6" from edge of platform. At the northern end of the northbound platform, the columns measure 3'-6" from the platform edge and 1'-8" from a vent wall (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 38" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

161st Street Yankee Stadium Street

1.30 – MR 220 | 155th Street 8th Avenue Station

__Summary:__ 155th Street 8th Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 23" (see figure 1).

Description

The 155th Street 8th Avenue Station is a below grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-4" throughout. The platforms are straight with one rows of columns approximately 3'-2" from edge of platform. At the platform staircases, the columns measure 3'-2" from the platform edge and 1'-4" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 38" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

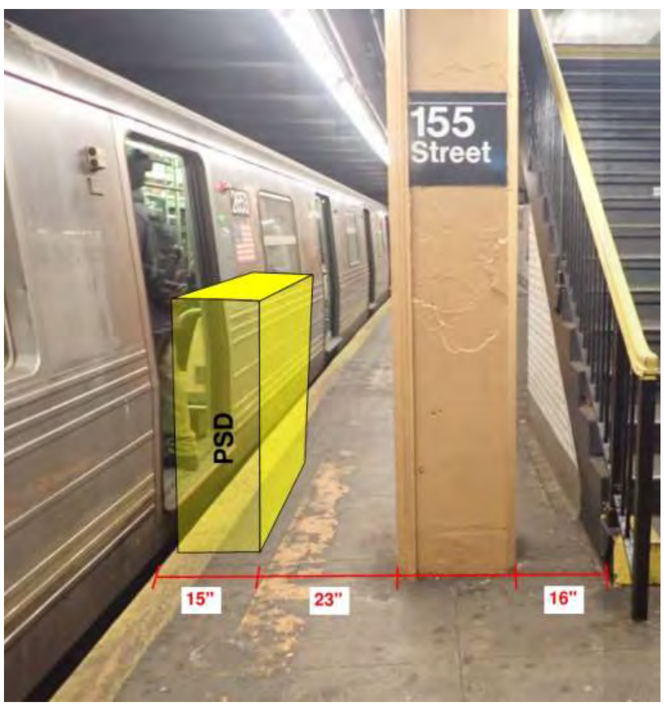

***Figure 1** – Area of ADA non-compliance*
155th Street 8th Ave Station

1.31 – MR 231 | Grand Street Station

Summary: *Grand Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1).*

Description

The Grand Street Station is a below grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 8'-8" throughout. The platforms are straight with one rows of columns approximately 3'-6" from edge of platform. At the platform staircases, the columns measure 3'-6" from the platform edge and 1'-8" from the staircase (see figure 1 for reference). The implementation of a platform edge barrier would reduce the currently compliant width of 42" to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

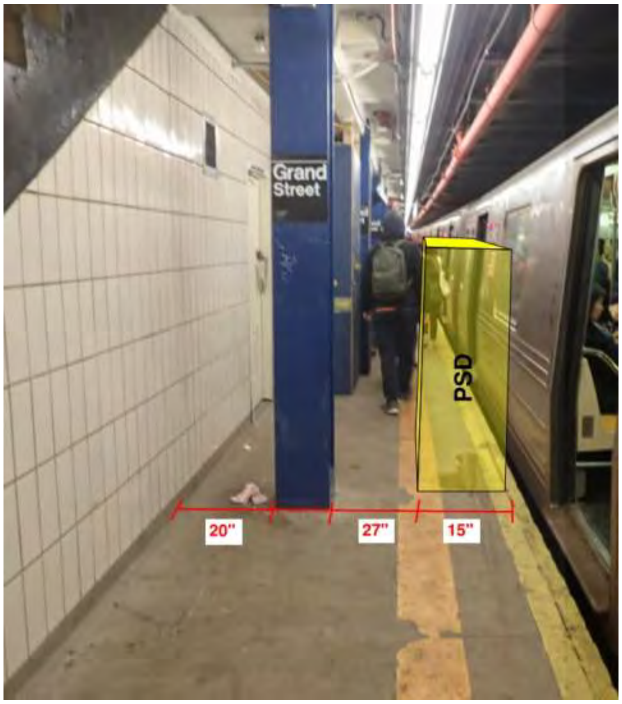

Figure 1 – *Area of ADA non-compliance*
Grand Street Station

1.32 – MR 277 | 7th Avenue Station

Summary: *7th Avenue Station is feasible for both APGs and PSDs. There are four ceiling mounted signals located at the lower platform edges which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

7th Avenue Station is a below-grade station with two levels of center / island platforms **(see Figure 1)**. The B train utilizes the south side of both the upper and lower platform. The platform structures are cast-in-place concrete. At the upper level platform, column faces are typically 5'-4" from the platform edge and the platform measures 29'-4" wide throughout. At the lower level platform column faces typically measure 2'-8" from the Queens-bound platform edge and 3'10" from the Uptown-bound platform edge. The platform width varies from 13'-0" to 24'-8". On the lower platform there are four ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the western end of the upper level platform adjacent to staircase P9 and at the center of the lower platform (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would at a minimum be required for the installation of an APG system.

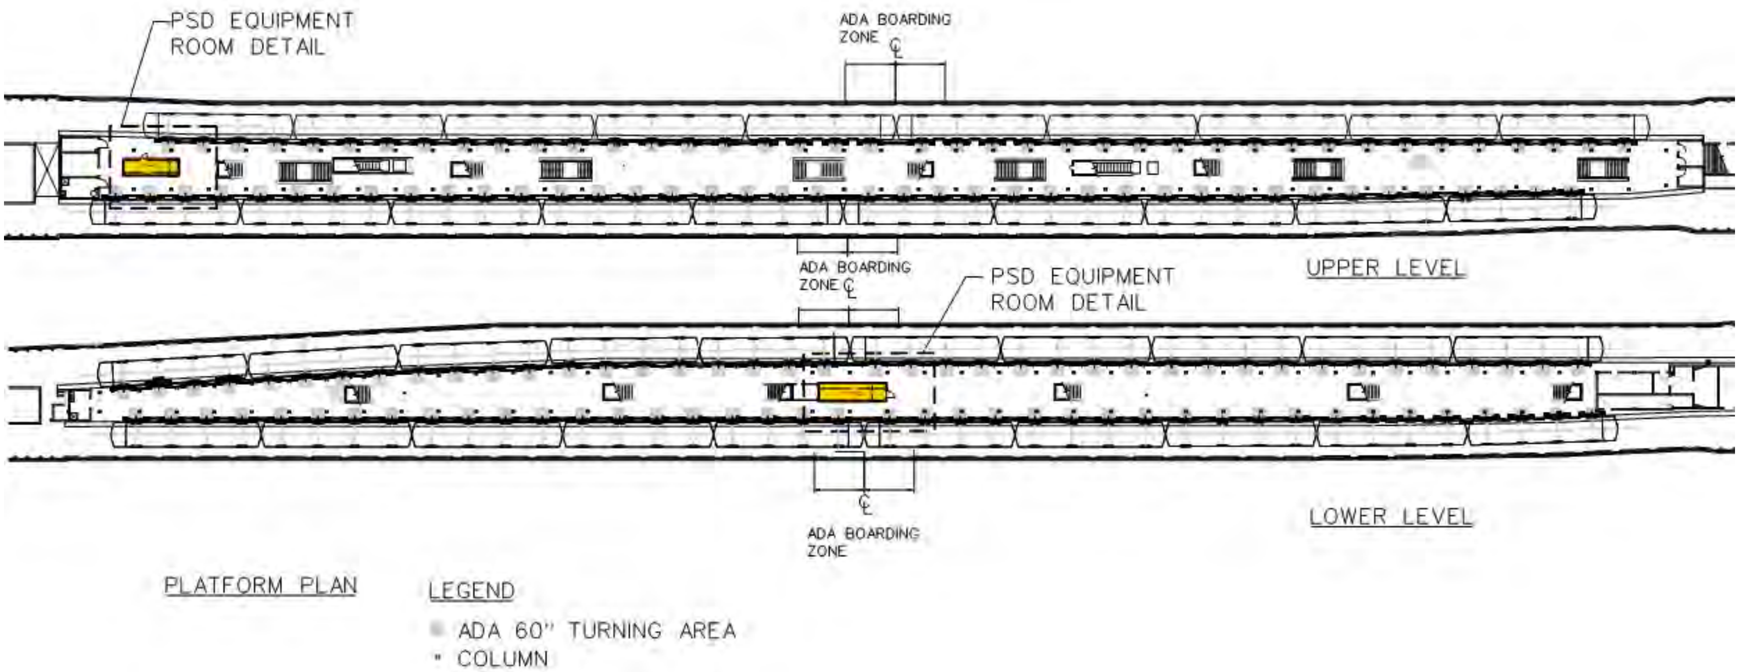

***Figure 1** – Overall Station Plan*
7th Avenue Station

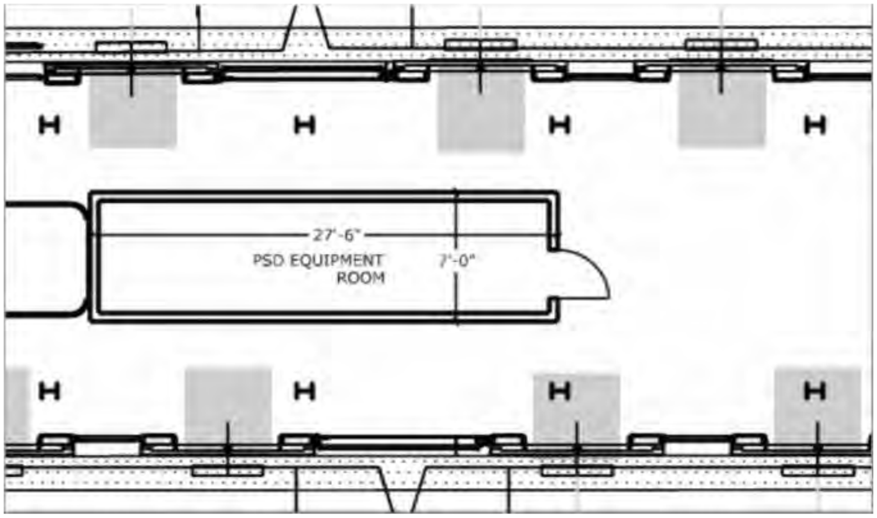

Figure 2 *– PSD Equipment Room 1 Detail*
7th Avenue Station

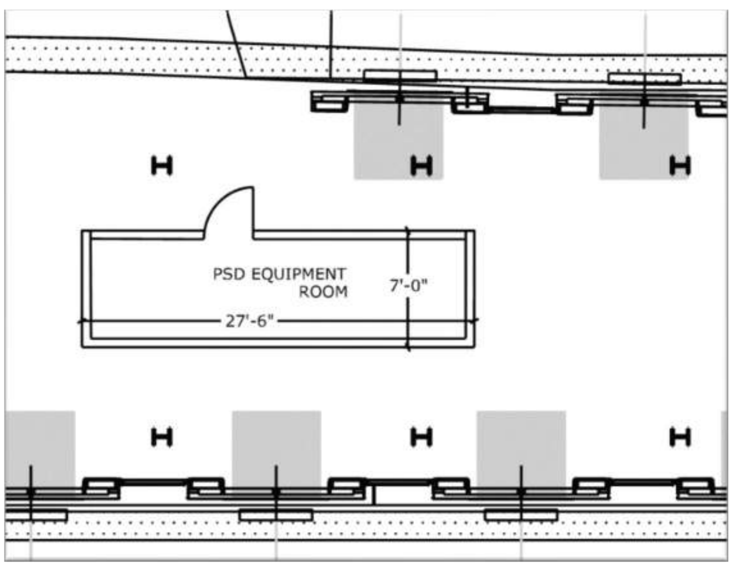

Figure 3 *– PSD Equipment Room 2 Detail*
7th Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	7th Avenue
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	76.8
Apparent Power (kVA)	96.0
Station Peak Demand Load, Max Current, (A)	266.7
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.8
Total Load (Station Peak + PSD), (A)	607
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	193
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter reading, for each Normal & Reserve service.

Table 1- *Power Capacity Analysis (Normal)*

Station Power Capacity Analysis (Reserve service)

Station Name	7th Avenue
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	78.0
Apparent Power (kVA)	97.5
Station Peak Demand Load, Max Current, (A)	270.8
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.8
Total Load (Station Peak + PSD), (A)	612
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	188
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter reading, for each Normal & Reserve service.

Table 2- *Power Capacity Analysis (Reserve)*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.5M to install APGs and $42.4M to install PSDs (See Appendix E)

7th Avenue Station

Appendices: Table of Contents

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for <u>Tier 2 Stations'</u> screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for <u>Tier 3 Stations</u> will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

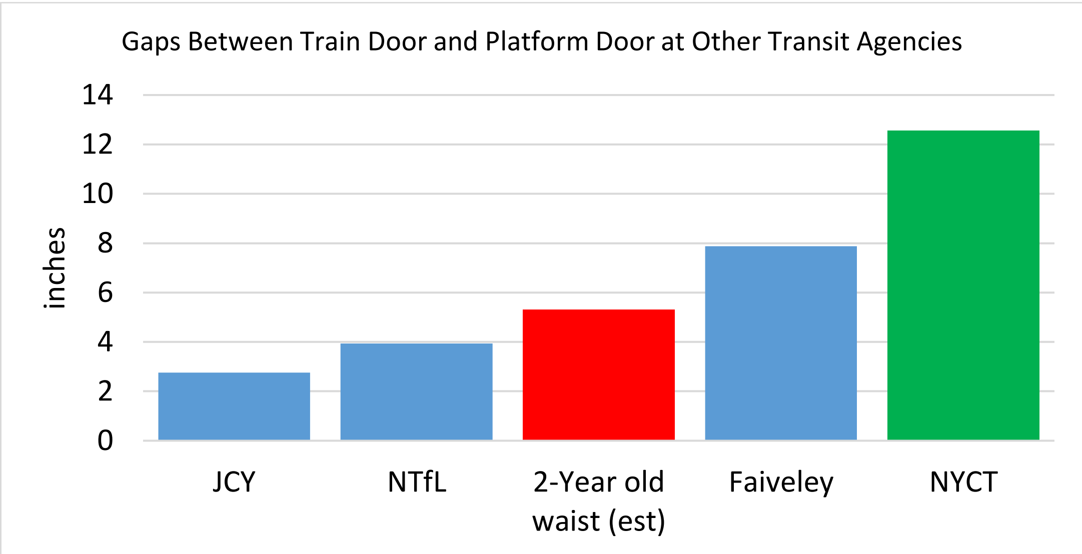

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

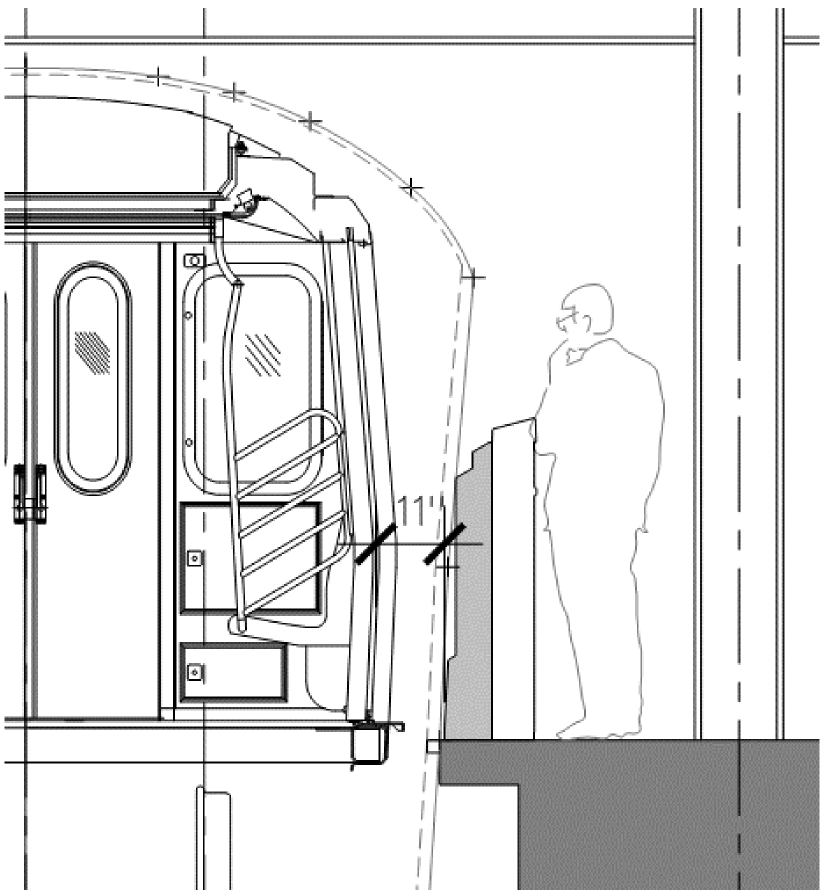

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

304 Turning Space

304.1 General. Turning space shall comply with 304.

304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.

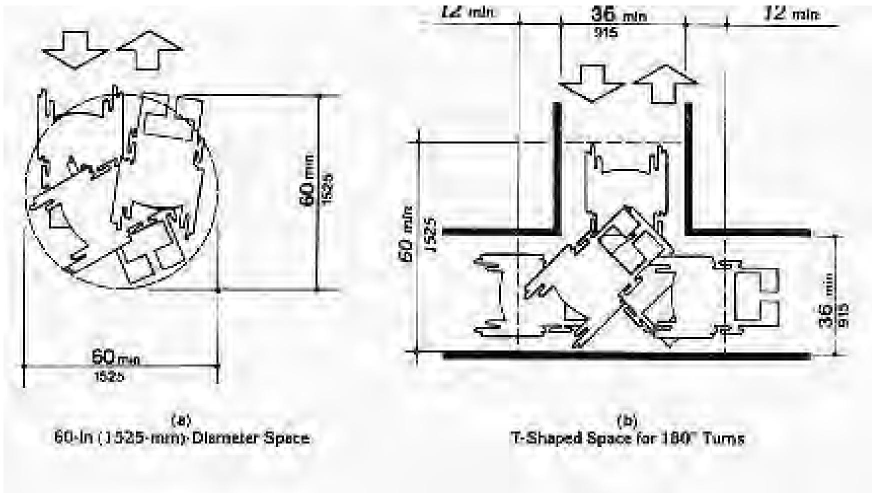
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

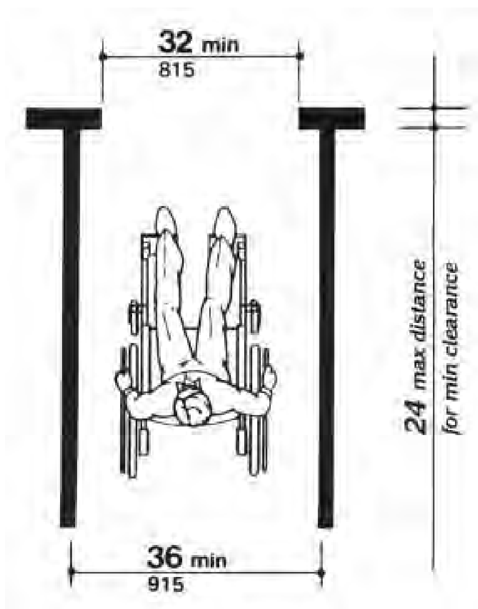


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

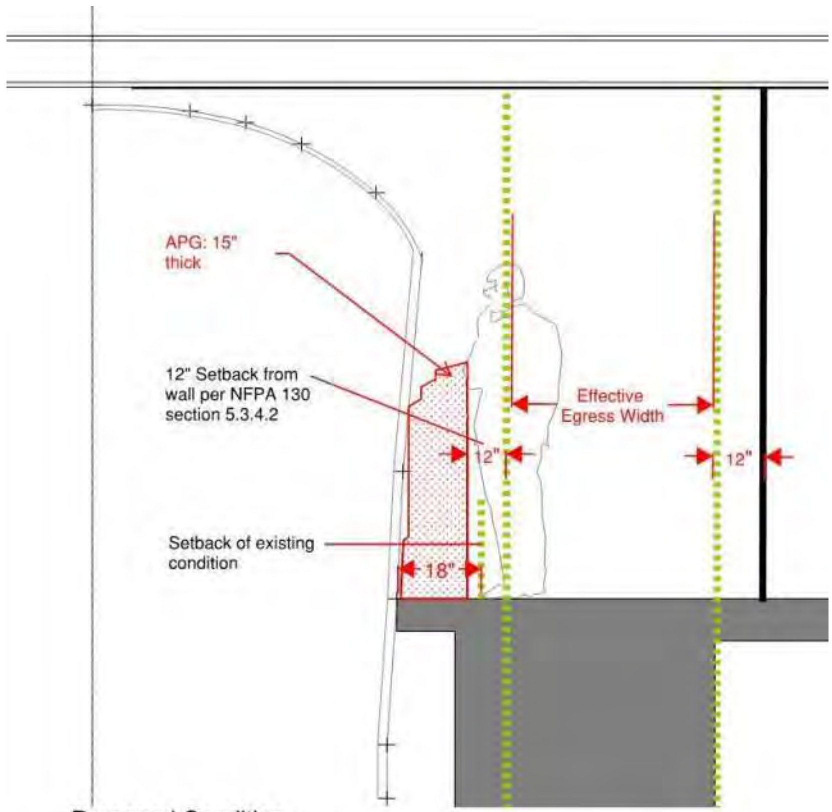
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Table of Contents   Appendix Table of Contents

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

Table of Contents Appendix Table of Contents

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

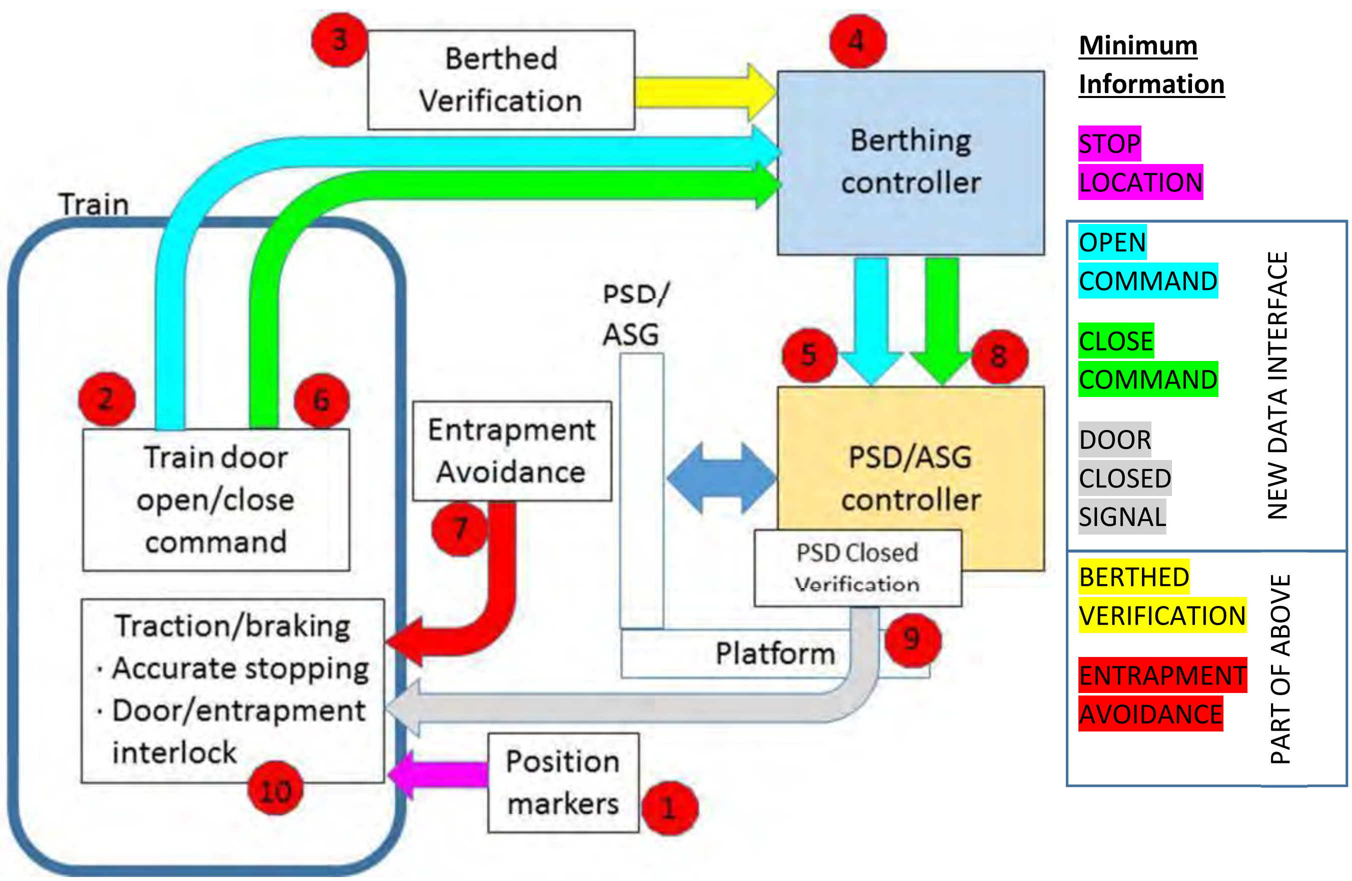
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

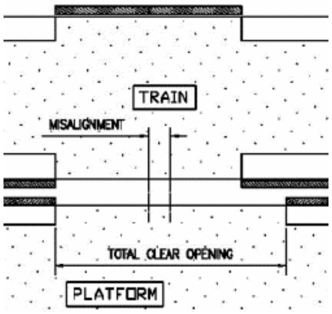
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

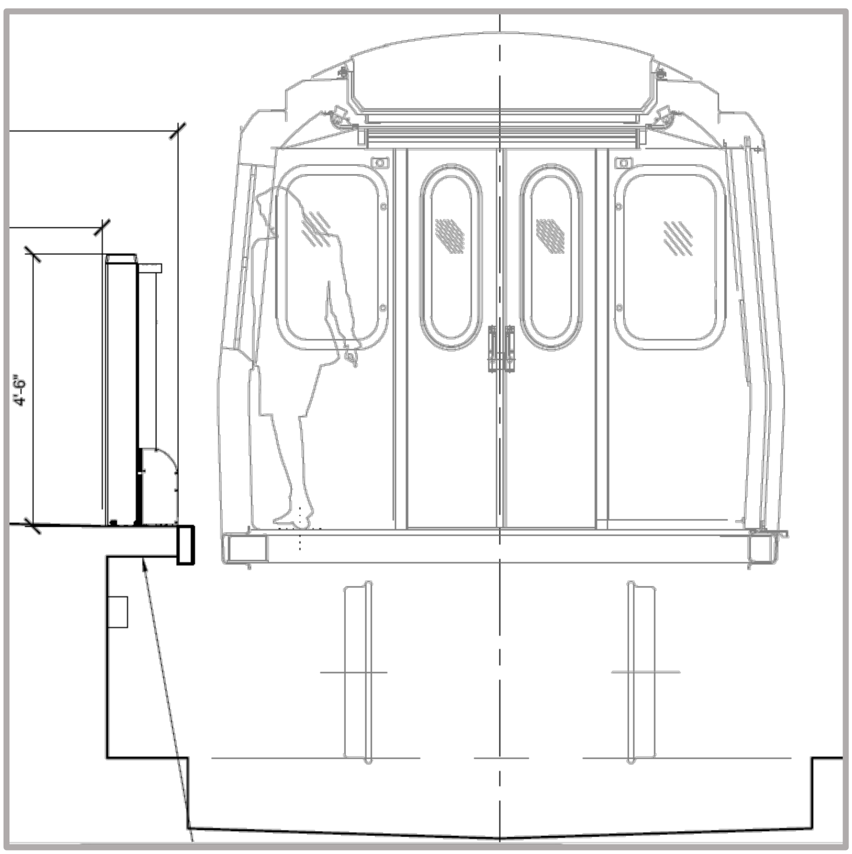


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

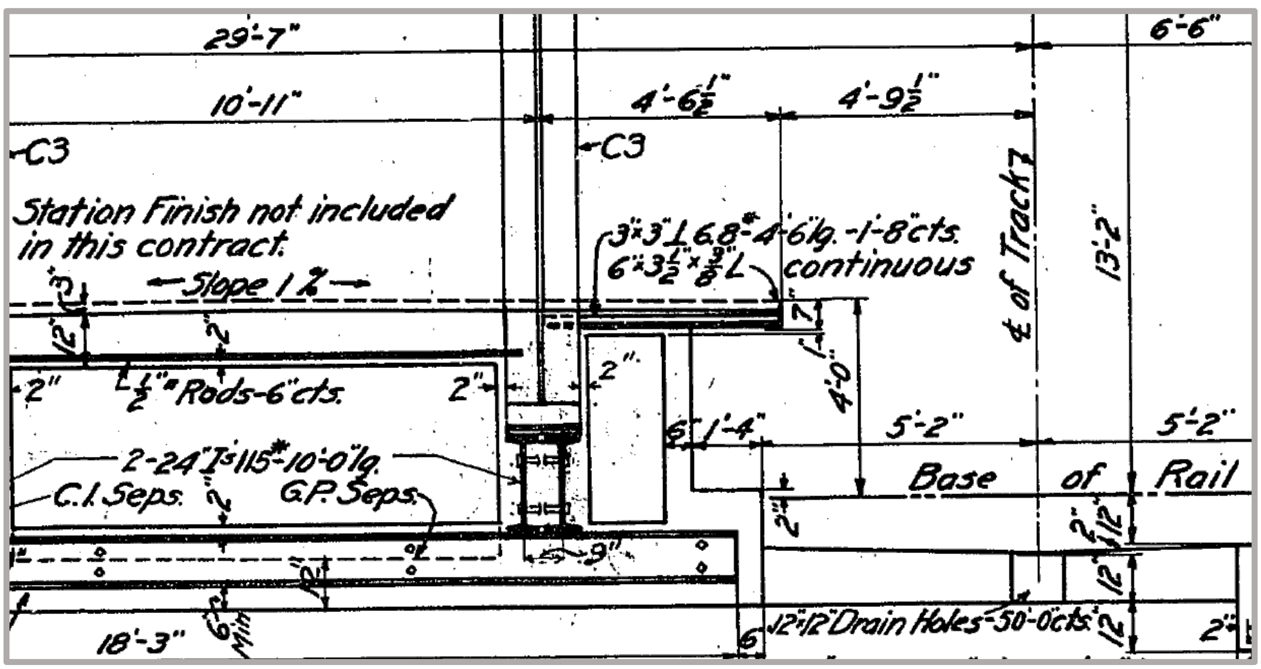

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

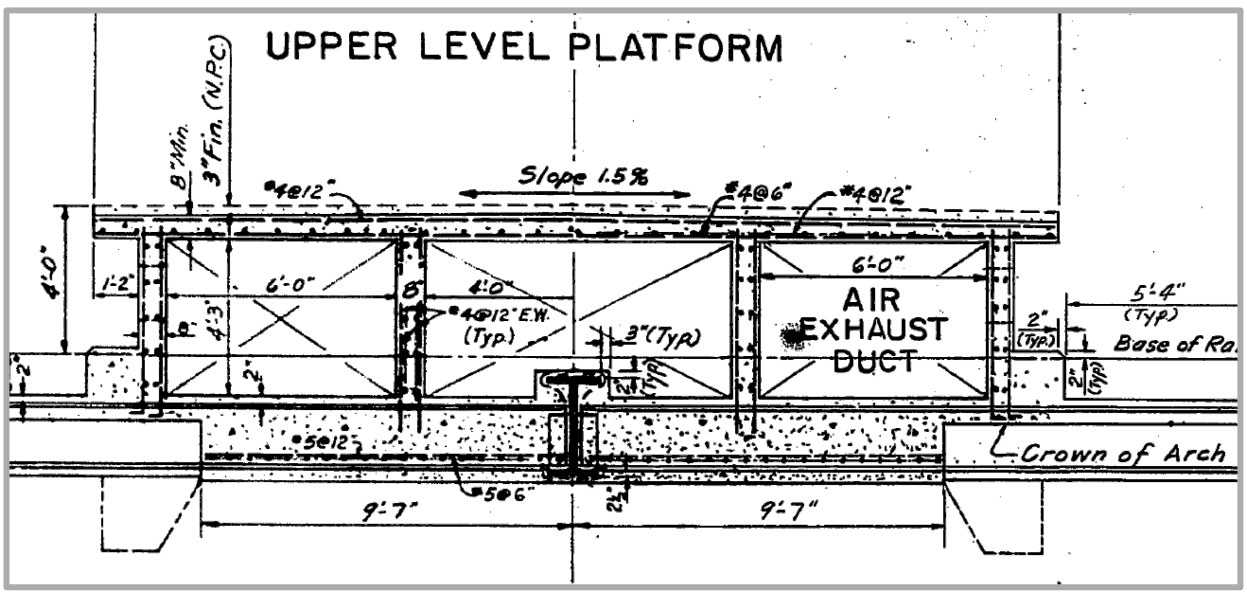

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

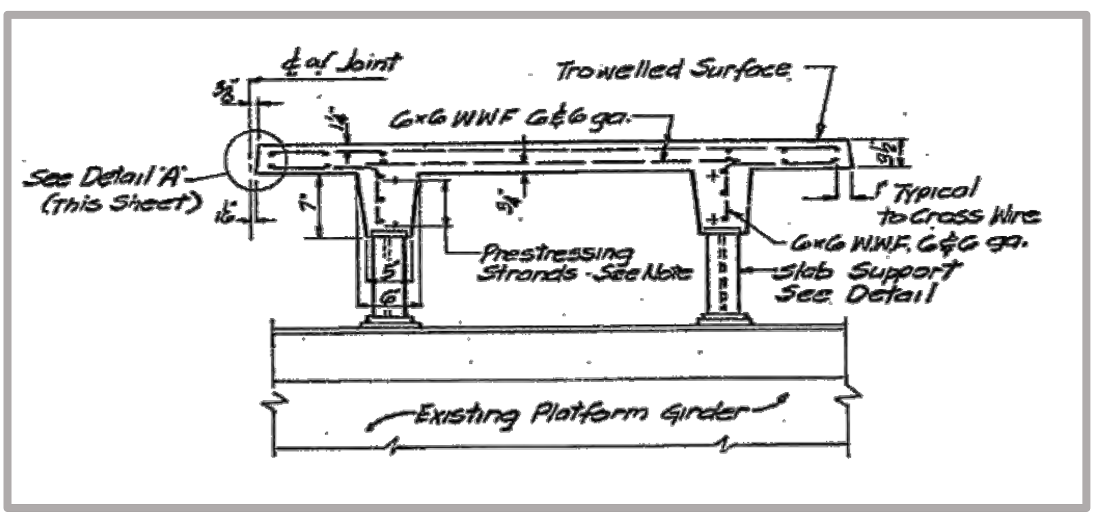

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

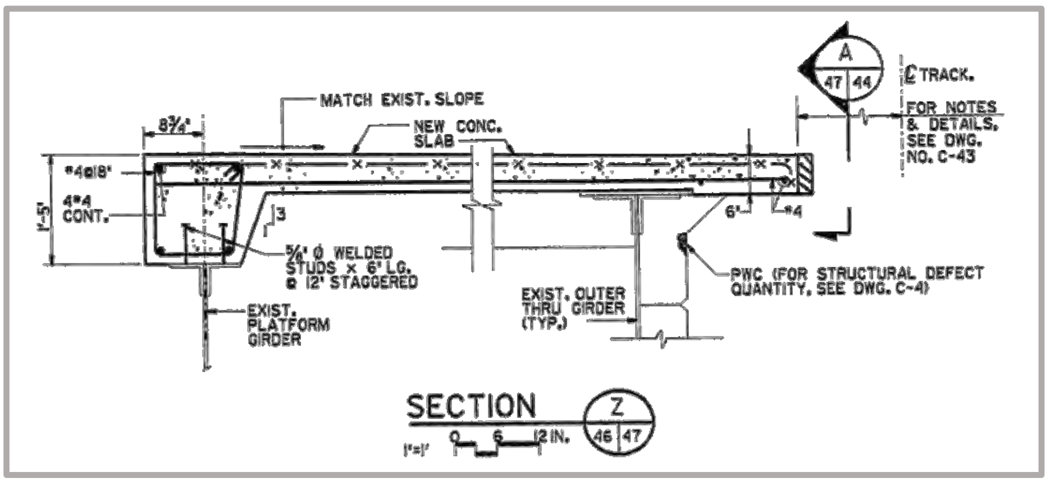

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

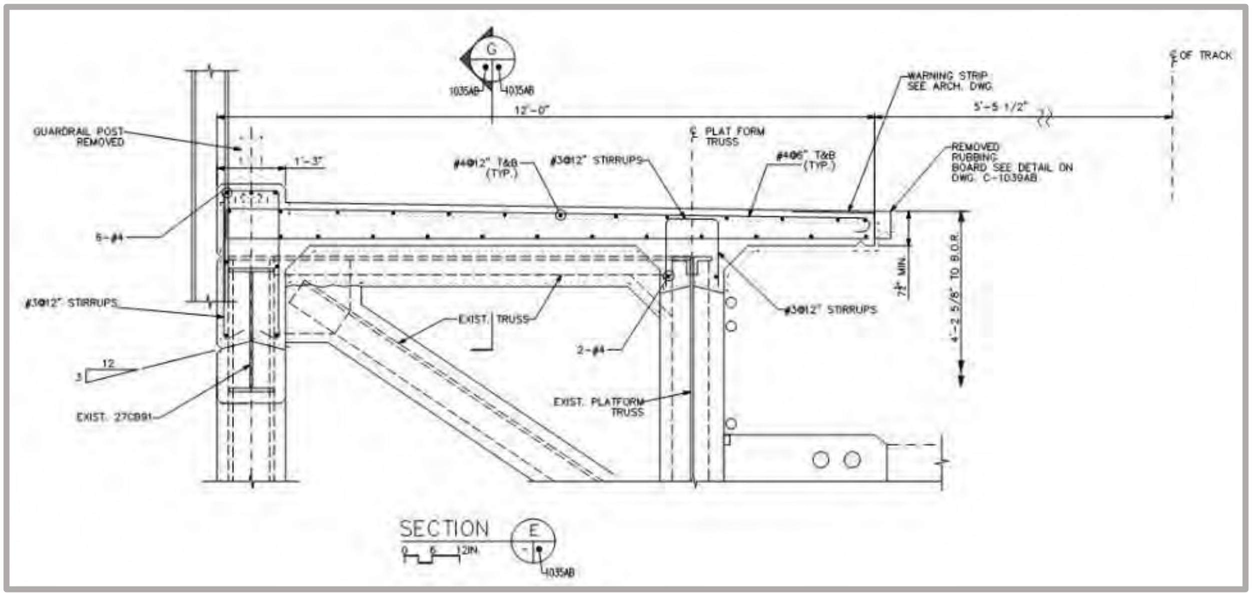

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

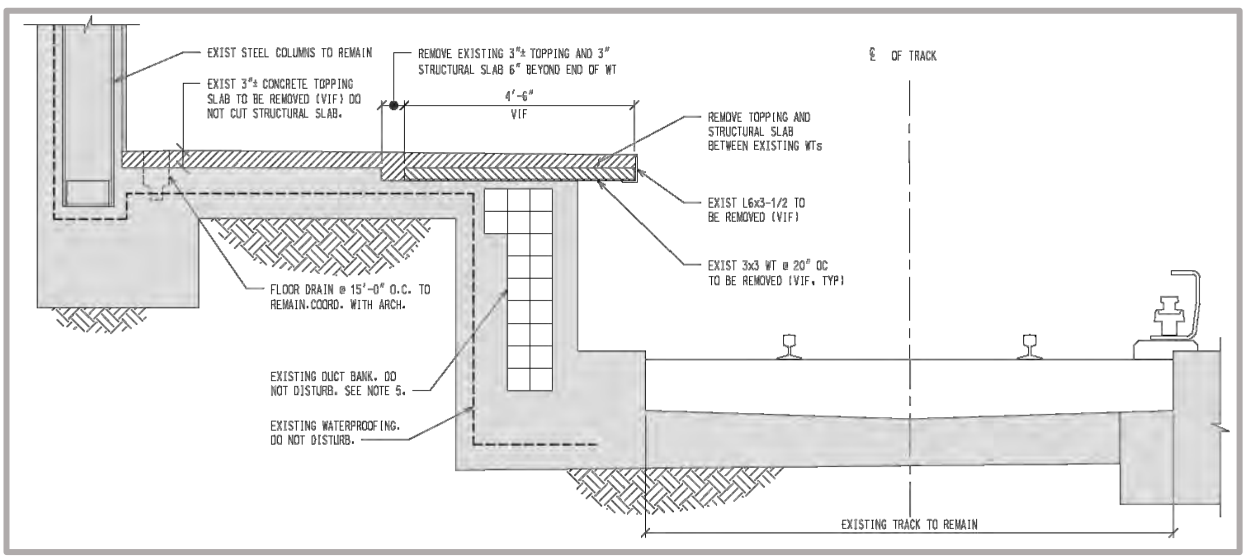

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

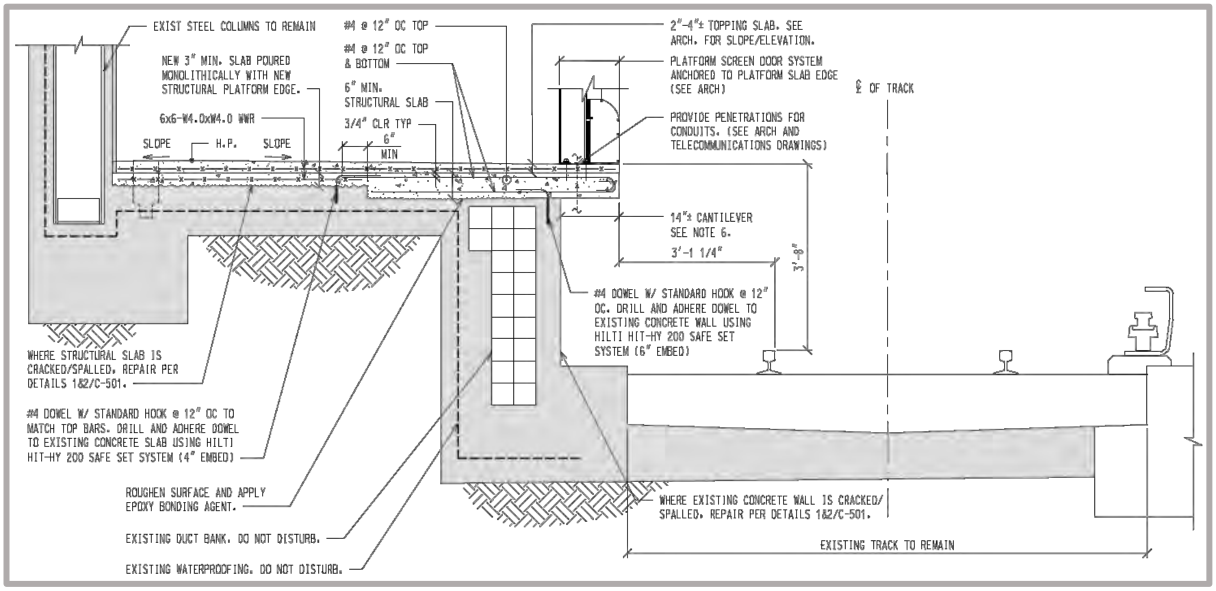

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

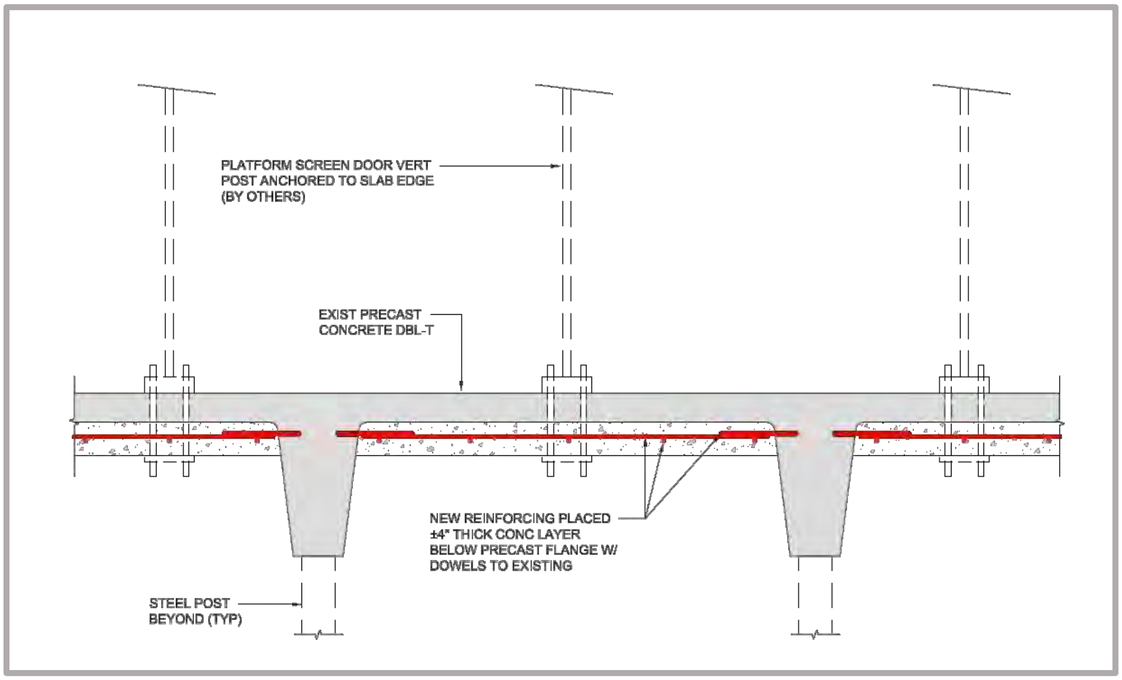

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Emergency Egress Width Analysis

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

MTA/NYCT

June 3, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

MTA/NYCT

June 3, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

3-Jun-19

STATION : 125TH ST. NICHOLAS AVE.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	634	LF		
5	LENGTH OF THE PLATFORM EDGE =	634	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,268**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,268	LF	7	8,876
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,340	SF	12	76,080
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	128	CY	2,500	320,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,270	EA	25	31,750
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,270	EA	25	31,750
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,268	LF	95	120,460
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,268	LF	15	19,020
26	Remove existing platform tiles	1,268	LF	12	15,216
27	Sawcut existing topping concrete at perimeter of removal area	1,268	LF	5	6,340
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,608	SF	8	60,864
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 7'-0" wide	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,268	SF	15	19,020

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

3-Jun-19

STATION : 174TH 175TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	671	LF		
5	LENGTH OF THE PLATFORM EDGE =	671	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,342**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,342	LF	7	9,394
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,710	SF	12	80,520
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,344	EA	25	33,600
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,344	EA	25	33,600
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,342	LF	95	127,490
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,342	LF	15	20,130
26	Remove existing platform tiles	1,342	LF	12	16,104
27	Sawcut existing topping concrete at perimeter of removal area	1,342	LF	5	6,710
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,052	SF	8	64,416
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 8'-7" wide	687	SF	8	5,493
30	New Work				
31	New concrete topping to match existing	1,342	SF	15	20,130

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

3-Jun-19

STATION : 167TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	659	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	659	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,318**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,318	LF	7	9,226
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,590	SF	12	79,080
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,320	EA	25	33,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,320	EA	25	33,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,318	LF	95	125,210
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,318	LF	15	19,770
26	Remove existing platform tiles	1,318	LF	12	15,816
27	Sawcut existing topping concrete at perimeter of removal area	1,318	LF	5	6,590
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,908	SF	8	63,264
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 5'-9" wide	460	SF	8	3,680
30	New Work				
31	New concrete topping to match existing	1,318	SF	15	19,770
32	New concrete topping at ADA boarding area to match existing	460	SF	15	6,900

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

3-Jun-19

STATION : 167TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [12'-0" x 16'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,646	SF	750	1,984,500
61	Spare Parts - Approx. 10% of Material Cost	1	LS	245,730	245,730
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
71	Allow for conduit / cable runs for power and communications under platform edge	1,318	LF	60	79,080

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for B - Line Stations

3-Jun-19

STATION : 167TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
74	Power to PSD Room from EDR including track crossing if needed	100	LF	60	6,000
75	Reserve power to PSD Room from EDR including track crossing if needed	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
79	MISC				
80	Testing and commissioning	1	LS	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘’ SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: June 7, 2019

STV 100 Years

Table of Contents

Appendices

Appendix A: Tier 2-3 Technology Assessment
Appendix B: Structural Feasibility Report
Appendix C: Emergency Egress Width Analysis
Appendix D: Maintenance Cost Estimate
Appendix E: Rough Order of Magnitude Costs

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 41 newly evaluated stations, 36 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.
- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the D-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 12% of the 'D' Line Stations. Total implementation cost would be \$159.4M for APGs and \$204.5M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of \$931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be \$4.6M.

Summary Table

(12% Feasible 5/41)

1.0 Station Assessments

1.01 – MR 026 | Dekalb Avenue Station

Summary: *Dekalb Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

Dekalb Ave Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. The platform columns are spaced 10'-10" on center, and column faces typically measure 3'-8" from the platform edge. The platform width is 15'-8" throughout. At the platform staircases, the columns flanking the stairs measure 3'-8" from the platform edge and are touching the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 44" to 29" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

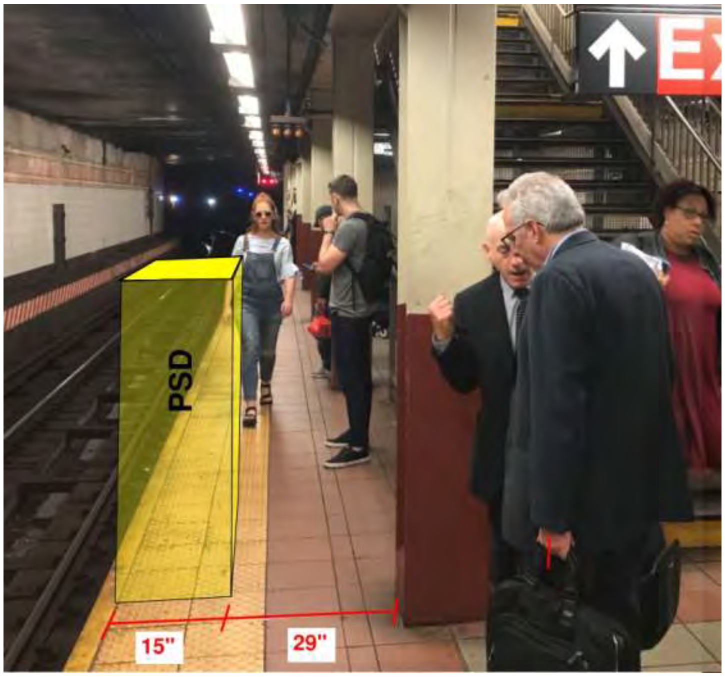

Figure 1 *– Non-Compliant ADA condition Dekalb Avenue Station*

1.02 – MR 027 | Atlantic Avenue/ Barclays Center Station

Summary: *Atlantic Ave Station is feasible for both APGs and PSDs. At the southbound platform, two columns adjacent to the platform edge would require removal and replacement at a more distant location. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Atlantic Ave Station is a below grade with two center / island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 15' on center, and column faces are at varying distances from the platform edge. The platform width is 18'-8" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. Both equipment rooms could be located at the south mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

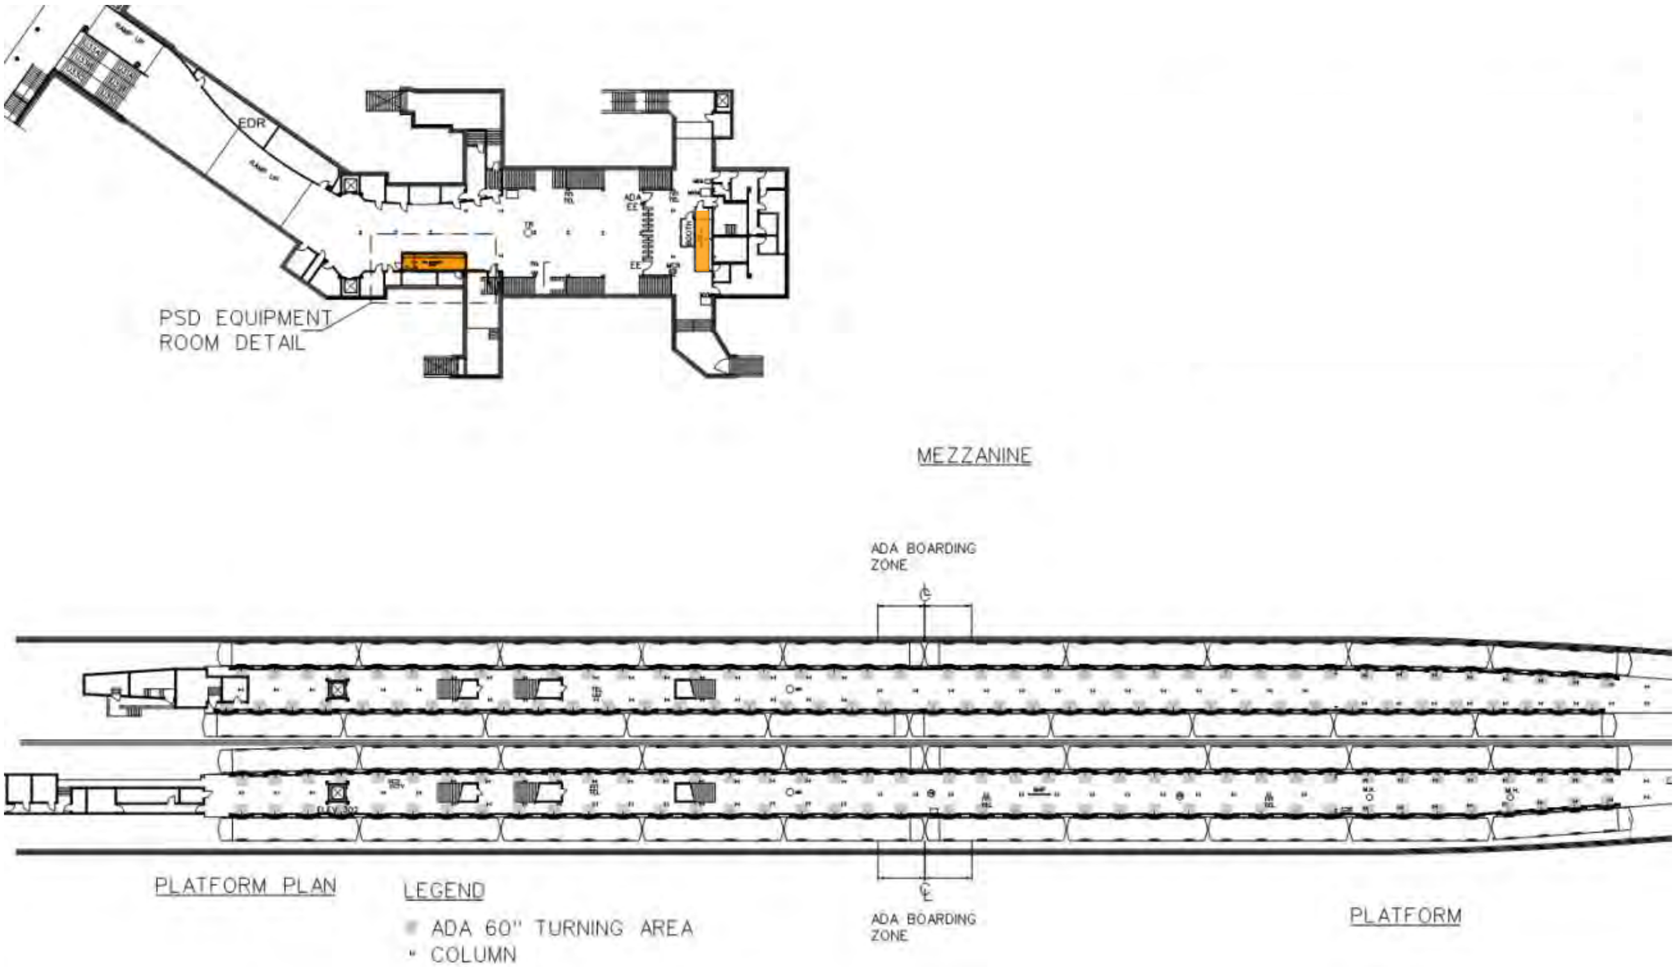

***Figure 1** – Overall Station Plan*
Atlantic Ave Station

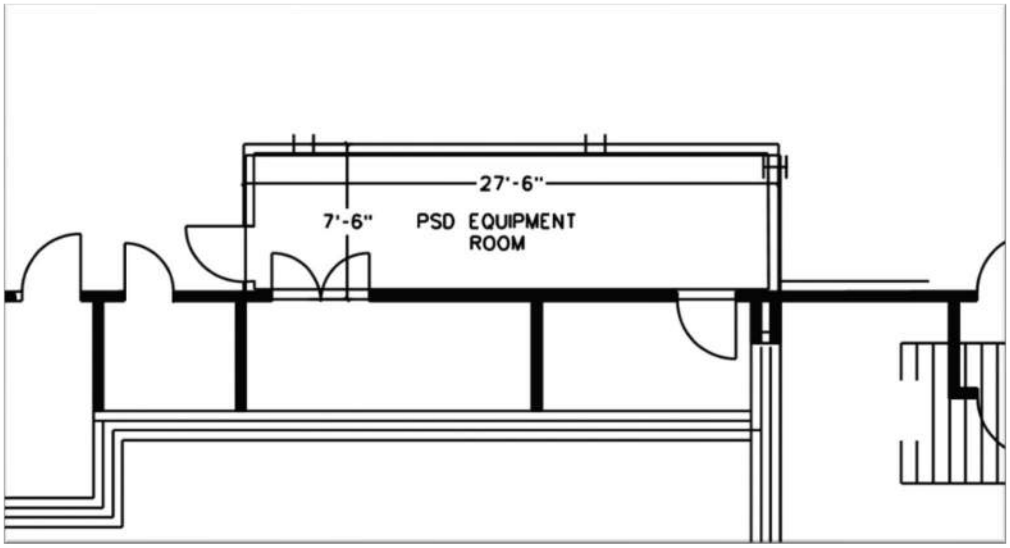

Figure 2 *– PSD Equipment Room 1 Detail*
Atlantic Ave Station

Platform obstructions within 5' of edge:

Southbound Track:

- One column is at 1'-0" from each platform edge. They will require removal and replacement as part of any PSD installation.

Northbound Track:

- None

These obstructions do not present an impediment to the installation of PSDs beyond the instances mentioned above.

Historic Restrictions:

The Atlantic Avenue station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Atlantic Ave. Barclays Ctr.
Peak Demand Load from ConEd Report, (kW)	88.8
Apparent Power (kVA)	111.0
Station Peak Demand Load, Max Current, (A)	308.3
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	649
Station Service Power Capacity, (Main SB or SG Rating), (A)	1600
Service Spare Capacity, (A)	951
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 1600A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service.

***Table 1**- Power Capacity Analysis (Normal Service)*

Station Power Capacity Analysis (Reserve Service)

NYCT Station MR Number	27
Station Name	Atlantic Ave. Barclays Ctr.
Peak Demand Load from ConEd Report, (kW)	55.2
Apparent Power (kVA)	69.0
Station Peak Demand Load, Max Current, (A)	191.7
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	532
Station Service Power Capacity, (Main SB or SG Rating), (A)	1600
Service Spare Capacity, (A)	1068
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 1600A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service.

***Table 1**- Power Capacity Analysis (Reserve Service)*

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $39.9M to install PSDs (See Appendix E).

***Figure 3** – View of column at platform edge requiring removal and replacement*
Atlantic Ave Station

1.03 – MR 028 | Union Street / 4th Avenue Station

Summary: *Union Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Union Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 2'-6" from the platform edge at each platform at the northern third of the station. The remainder of the platforms is column-free. The platform width is 8'-8" throughout. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2 below shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

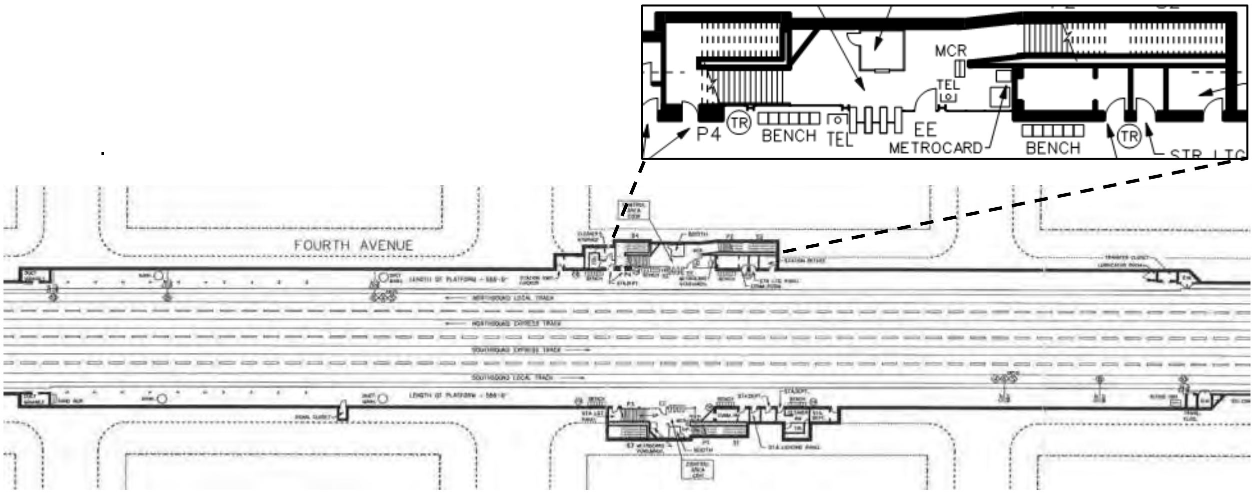

Figure 1 – *Congested/Narrow Station Plan*
Union Street Station

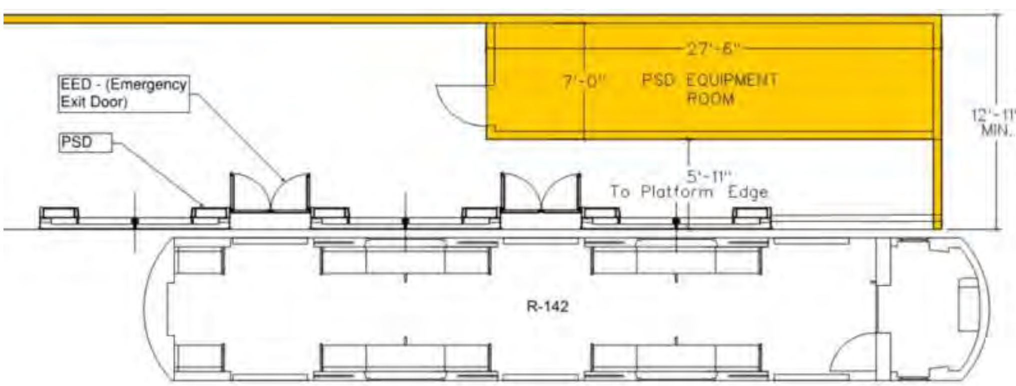

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions

1.04 – MR 029 | 4th Avenue/ 9th Street Station

Summary: *4th Ave / 9th St Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

4th Ave / 9th St Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 8'-4" to 8'-8"." Columns are spaced 11'-10" on center with column faces 3'-0" away from the edge. The columns are present only on the northern third of both the platforms; the remainder of the platforms are column-free. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

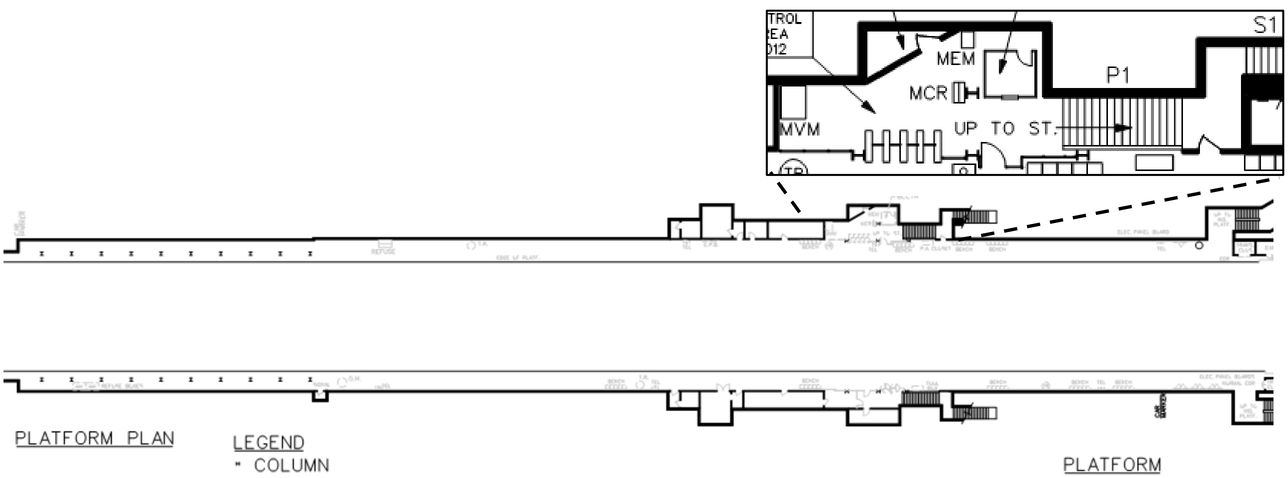

***Figure 1 –** Congested/Narrow Station Plan*
4th Ave / 9th Street Station

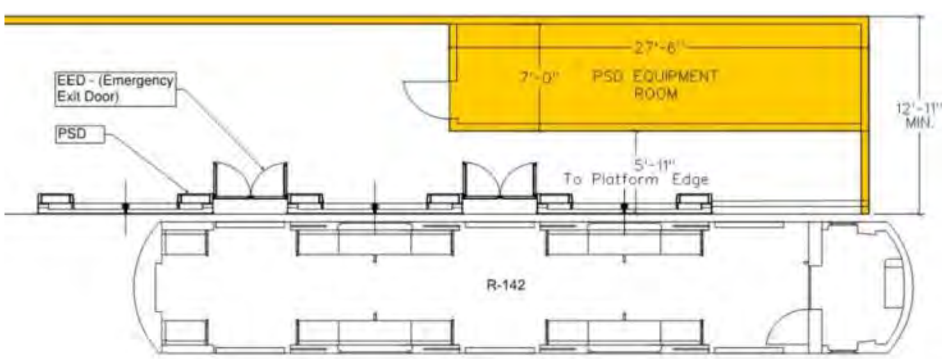

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.05 – MR 030 | Prospect Avenue Station

Summary: *Prospect Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

The Prospect Ave Station is a below-grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platforms is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms and control areas, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

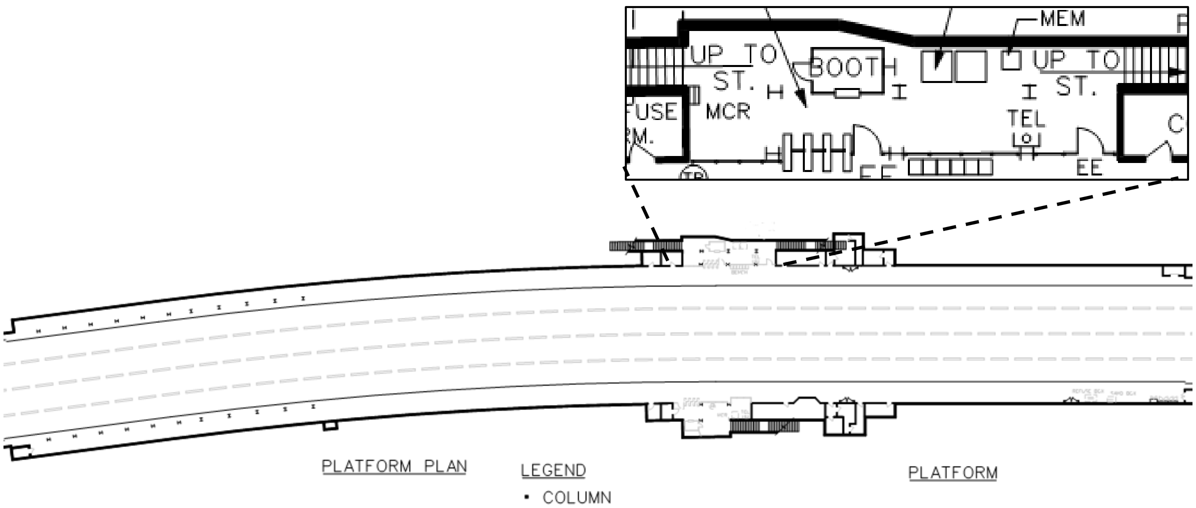

***Figure 1 –** Congested/Narrow Station Plan*
Prospect Avenue Station

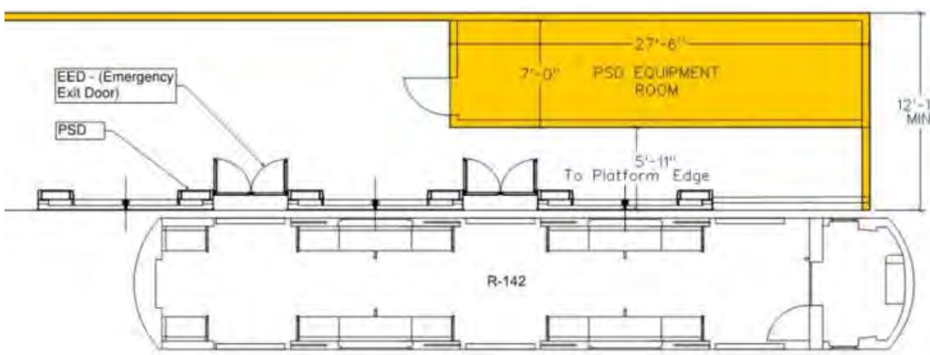

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.06 – MR 031 | 25th Street Station

Summary: *25th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

25th Street Station is a below grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platforms is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

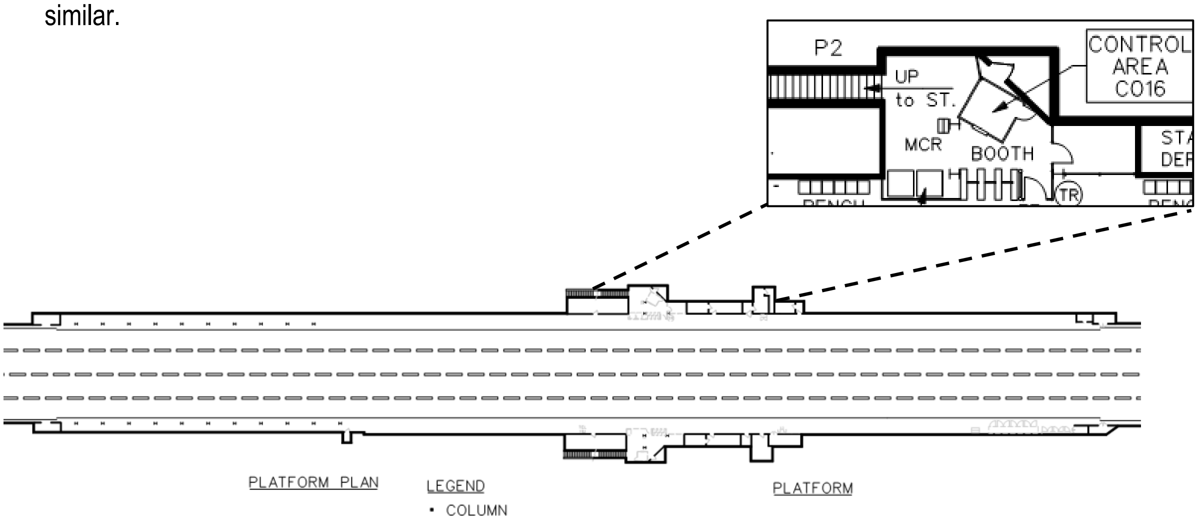

Figure 1 – *Congested/Narrow Station Plan*
25th Street Station

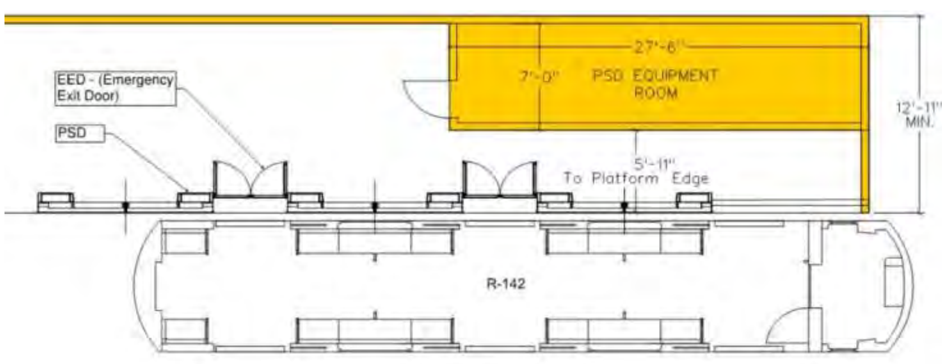

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

on

1.07 – MR 032 | 36th Street Station

Summary: *36th Street Station is not feasible for both APGs and PSDs due to the row of columns at 12" from the platform edge. (see figure 1).The barrier itself is15" thick and requires free space for maintenance purposes.*

Description

The 36th Street Station is a below-grade station with two center / island platforms. The platform structure is cast-in-place concrete. The width of the platforms varies from 13'-0" to 19'-2". Columns are spaced 15'-6" on center with column faces 1'-0" away from platform edges on the express side. The inside face of the barrier itself is 15" minimum from the concrete platform edge, and requires free space for maintenance and operation. **(see Figure 1)**.

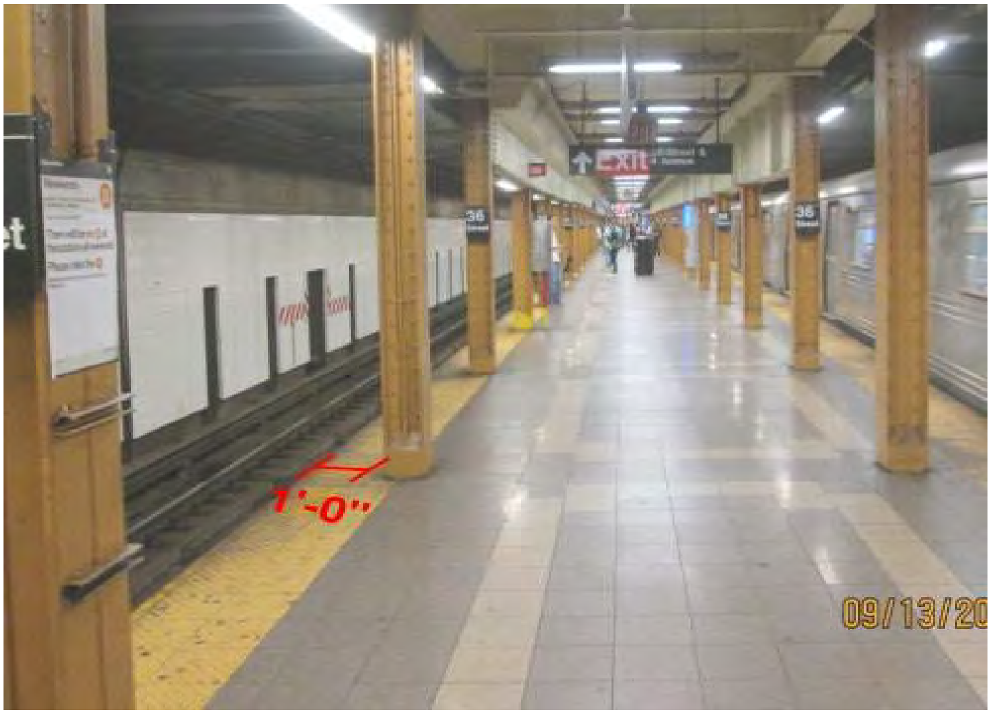

Figure 1 – *Obstruction within 12"*
36th Street Station

1.08 – MR 058 | Coney Island Stillwell Avenue Station

Summary: *Coney Island Stillwell Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 4'-6" (see figure 1).*

Description

Coney Island Stillwell Avenue Station is an elevated station with four straight island platforms. Each platform is dedicated to one of the following services, 'N', 'Q', 'F' and 'D' which is the subject of this report. The other services are addressed in previously issued reports. The platform structures are cast-in-place concrete. The width of the 'D' platform ranges from 19'-0' to 20'-6". The corridor width adjacent to the permanent structure at the south end of the platform shown in photo below, is 4'-6" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
Coney Island Stillwell Avenue Station

1.09 – MR 059 | 9th Avenue Station

Summary: *9th Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 9th Avenue Station is an at grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-0" throughout. The platforms are straight with two rows of columns measuring approximately 3'-4" from the platform edges. At the platform staircases, the columns measure 3'-4" from the platform edge and 0'-8" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

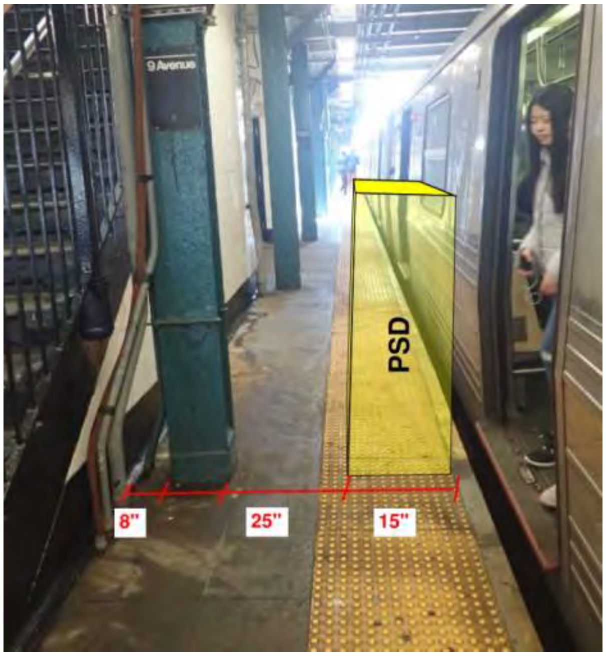

Figure 1 *– Non-compliant ADA dimension*
9th Avenue Station

.

1.10– MR 060 | Fort Hamilton Parkway Station

Summary: *Fort Hamilton Parkway is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The Fort Hamilton Parkway Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-4" to 11'-6". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Fort Hamilton Station

Figure 2 *– Precast Slab*
Fort Hamilton Station

1.11 – MR 061 | 50th Street Station

Summary: *50th Street is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 50th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-4" to 11'-6". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

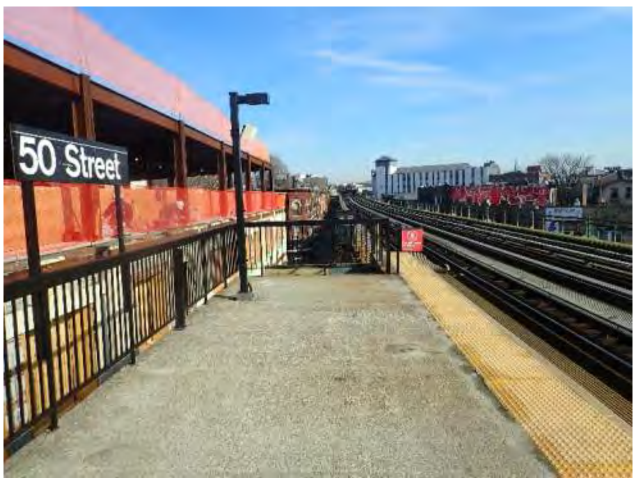

Figure 1 *– General Station Condition*
50th Street Station

Figure 2 *– Precast Slab*
50th Street Station

1.12 – MR 062 | 55th Street Station

Summary: *55th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 55th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-4" to 11'-10". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference

Figure 1 *– General Station Condition*
55th Street Station

Figure 2 *– Precast Slab*
55th Street Station

1.13 – MR 063 | 62nd Street Station

Summary: *62nd Street Station not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 62nd Street Station is an elevated station with two center/island platforms. The platform structures are precast concrete. The width of the platforms is approximately 15'-2" throughout. The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
62nd Street Station

Figure 2 *– Precast Slab*
62nd Street Station

1.14– MR 064 | 71st Street Station

Summary: *71st Street is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 71st Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-4" throughout. The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
71st Street Station

Figure 2 *– Precast Slab*
71st Street Station

1.15 – MR 065 | 79th Street Station

Summary:*79th Street Station not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 79th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-4" to 11'-10". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
79th Street Station

Figure 2 *– Precast Slab*
79th Street Station

1.16 – MR 066 | 18th Avenue Station

Summary: *18th Avenue Street not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 18th Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 10'-0" to 11'-8". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
18th Avenue Station

Figure 2 *– Precast Slab*
18th Avenue Station

1.17 – MR 067 | 20th Avenue Station

Summary: *20th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 2).*

Description

The 20th Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 6'-4" to 11'-6". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
20th Avenue Station

Bay 50th Street Station

***Figure 2** – Precast Slab*
Bay 50th Street Station

1.21 – MR 151 | 145th Street St. Nicholas Avenue Station

Summary: *145th Street St. Nicholas Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

The 145th Street St. Nicholas Avenue Station is a below grade station with two straight center / island platforms at each level of this two-level station. The B-train service utilizes the lower level. The platform structures are cast-in-place concrete. The width of the platforms at the platform staircases is 4'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA dimension*
145th Street Station

1.22 – MR 153 | 125th Street St. Nicholas Avenue Station.

Summary: *125th Street St. Nicholas Ave. Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

125th Street St. Nicholas Ave. Station is a below-grade station with two center / island platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the center of each platform and measure 8'-4" from the platform edge. The platform widths vary from approximately 17'-4" to 17'-10". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. Both equipment rooms could be located at the center of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

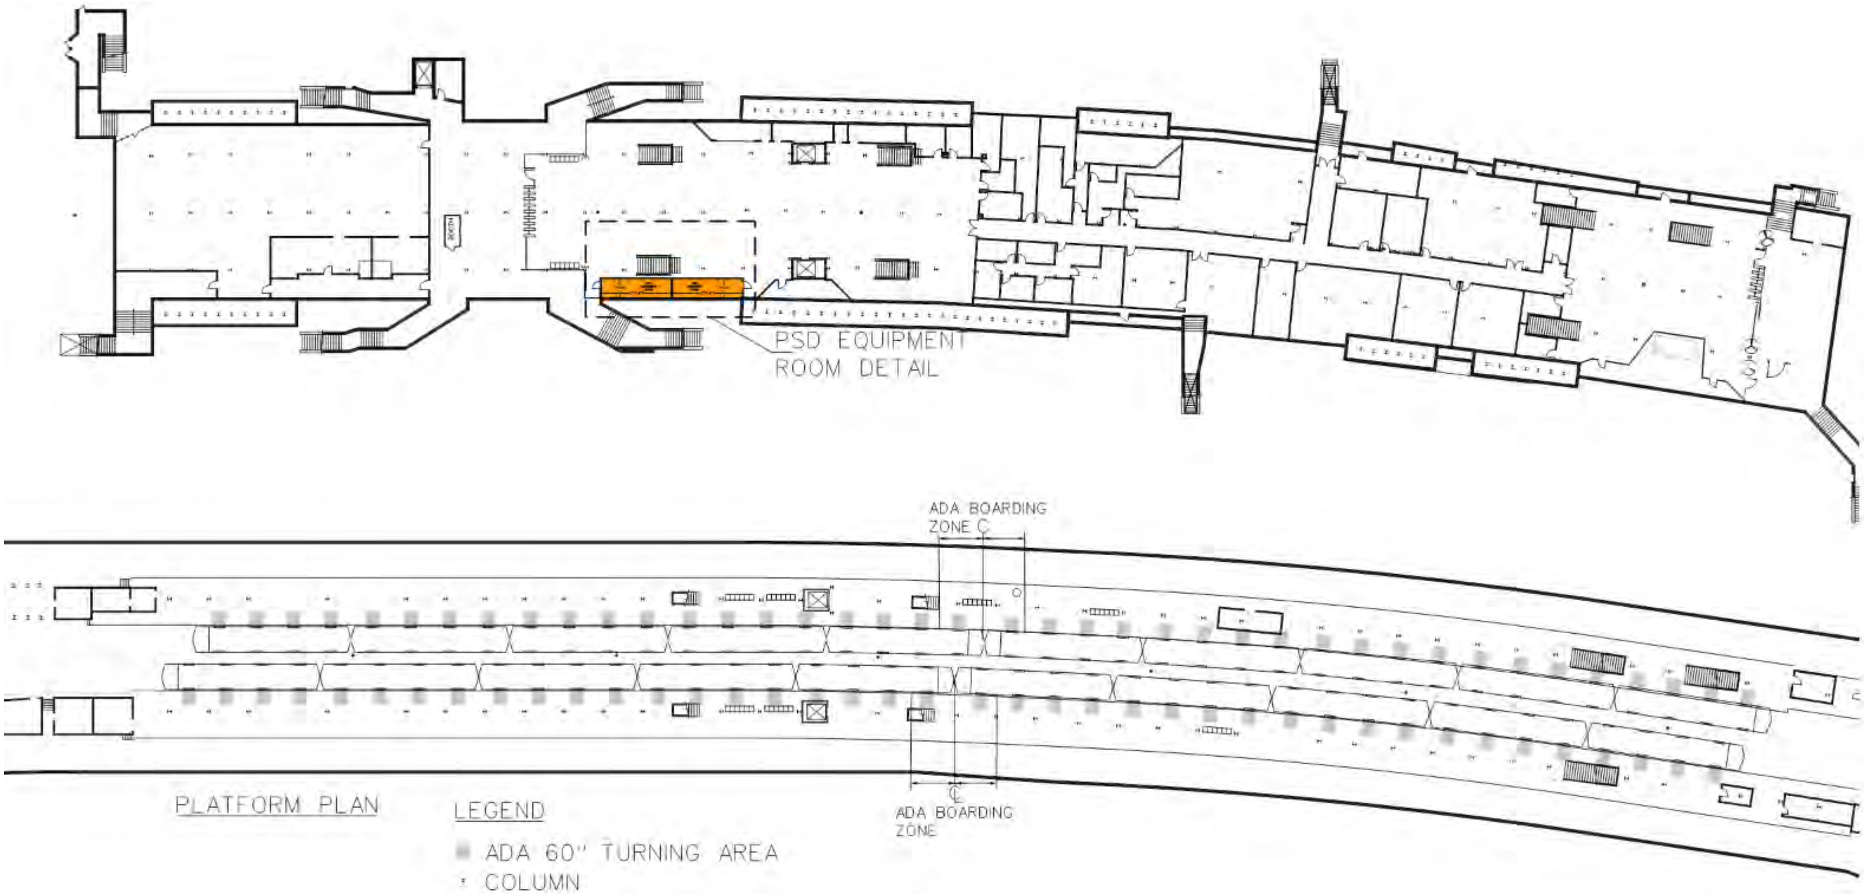

Figure 1 – Overall Station Plan
125th Street Station

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'D' Line Stations
(125th Street Station)

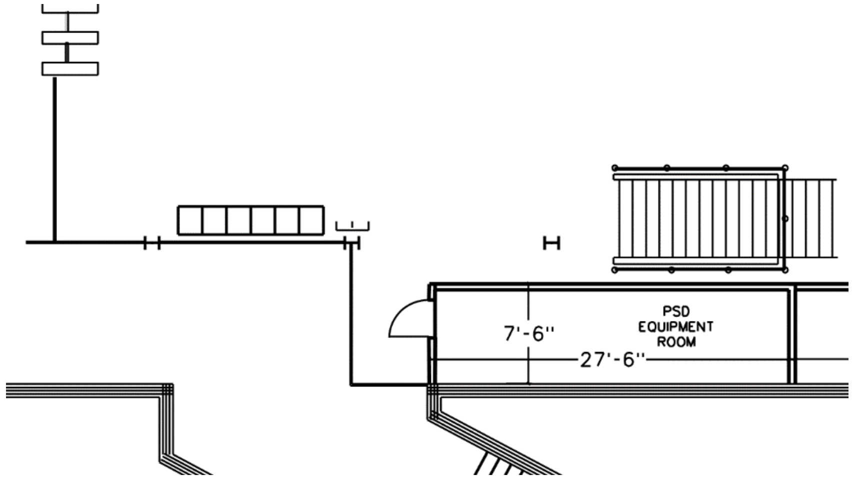

Figure 2 *– PSD Equipment Room Detail*
125th Street Station

Figure 3 *– Typical platform view*
125th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	125th Street St. Nicholas Ave.
Peak Demand Load from ConEd Report, (kW)	245.6 (combined)
Apparent Power (kVA)	307.0
Station Peak Demand Load, Max Current, (A)	852.8
Maximum Amount of Doors	160
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	1193
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	7
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 1200A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $41.5M to install PSDs (See Appendix E)

1.23 – MR 161 | 59th Street Columbus Circle Station

Summary: *59th Street Columbus Circle Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

59th Street Columbus Circle Station is a below-grade station consisting of two center / island platforms (there is a third island platform which is closed to the public). The platform widths vary from approximately 10'-8" – 29'-0". The platforms are mildly curved with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-0" from the platform edge and 2'-2" from the staircase .The implementation of a platform edge barrier would reduce the currently compliant width of 36" to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

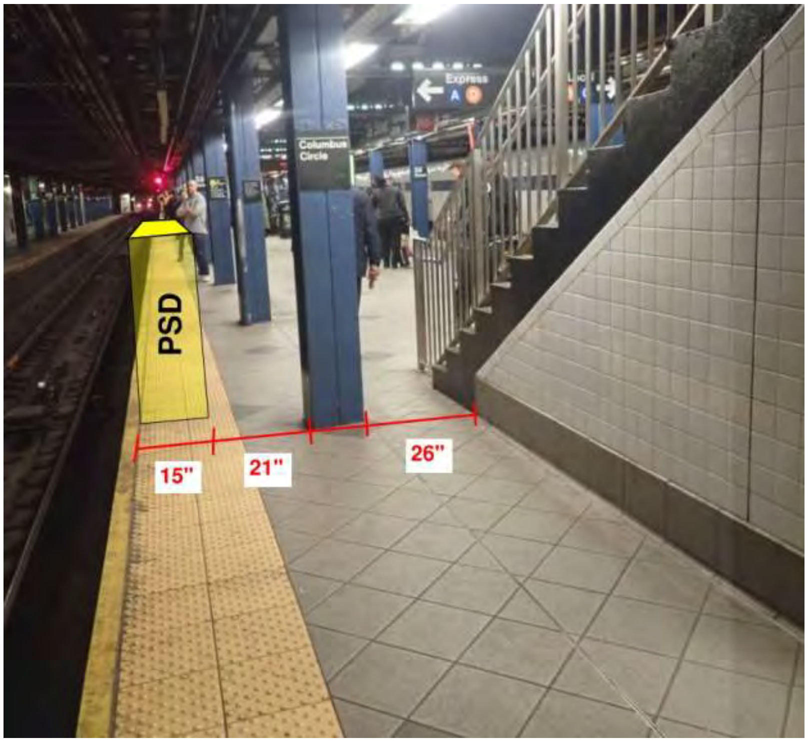

***Figure 1** –platform*
59th Street Columbus Circle Station

1.24 – MR 210 | 205th Street Norwood Station

***Summary:** 205th Street Norwood Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

205th Street Norwood Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 17'-6" throughout. The platforms are straight with two rows of columns measuring approximately 3'-4" from the platform edges. At the platform staircases, the columns measure 3'-4" from the platform edge and 0'-8" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
205th Street Norwood

1.25 – MR 211 | Bedford Park Blvd Station

Summary: *Bedford Park Blvd Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Bedford Park Blvd. Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 19'-0" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 26" from the staircase.The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** –platform*
Bedford Park Blvd Station

1.26 – MR 212 | Kingsbridge Road Station

***Summary:** Kingsbridge Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Kingsbridge Road Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 19'-6" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-8" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** –platform*
Kingsbridge Road Station

1.27 – MR 213 | Fordham Road Station

Summary: : *Fordham Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Fordham Road Station is a below-grade station consisting of two center / island platforms. The platform widths vary from approximately 10'-8" to 54'-8". The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-10" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
Fordham Road Station

1.28 – MR 214 | 182nd St 183rd St Station

Summary: *182nd-183rd St Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

182nd-183rd St Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-8" throughout. The platforms are straight with one row of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 2'-0" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

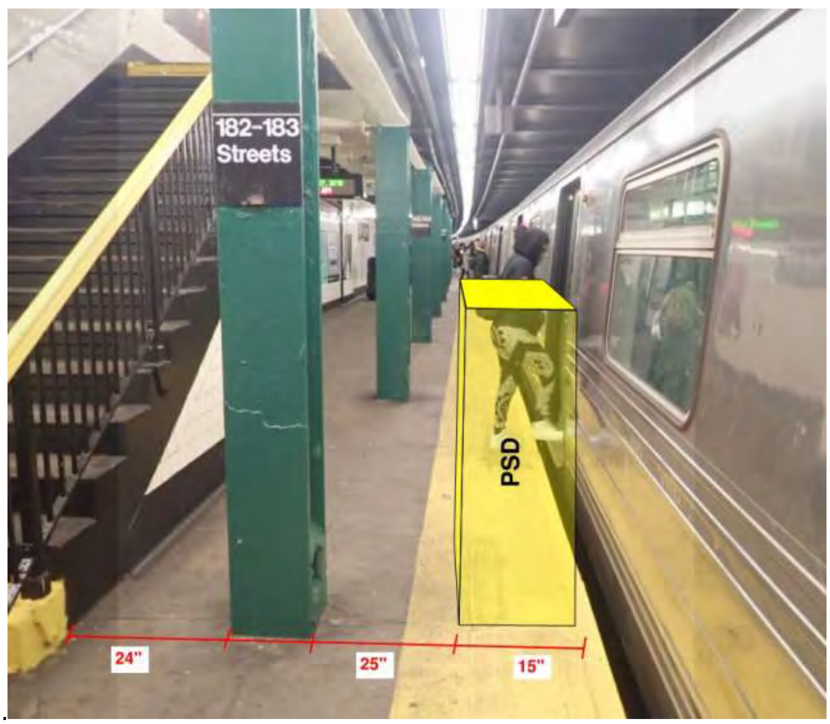

Figure 1 *– Non-Compliant ADA condition*
182nd-183rd Sts Station

1.29 – MR 215 | Tremont Avenue Station

Summary: *Tremont Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

Tremont Avenue Station is a below-grade station consisting of two center / island platforms. The platform widths are approximately 22'-0" throughout. The platforms are straight with two rows of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-4" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Tremont Avenue

1.30 –MR 216 | 174th St 175 St Station

Summary: *174th-175th St Station is feasible for both APGs and PSDs. There are two ceiling mounted monitors located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 174th-175th St Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are columns evenly distributed along the platform edge measuring 3'-6" from the platform edge. The platform widths vary from approximately 10'-8" to 21'-0". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 6'-8". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the edge of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

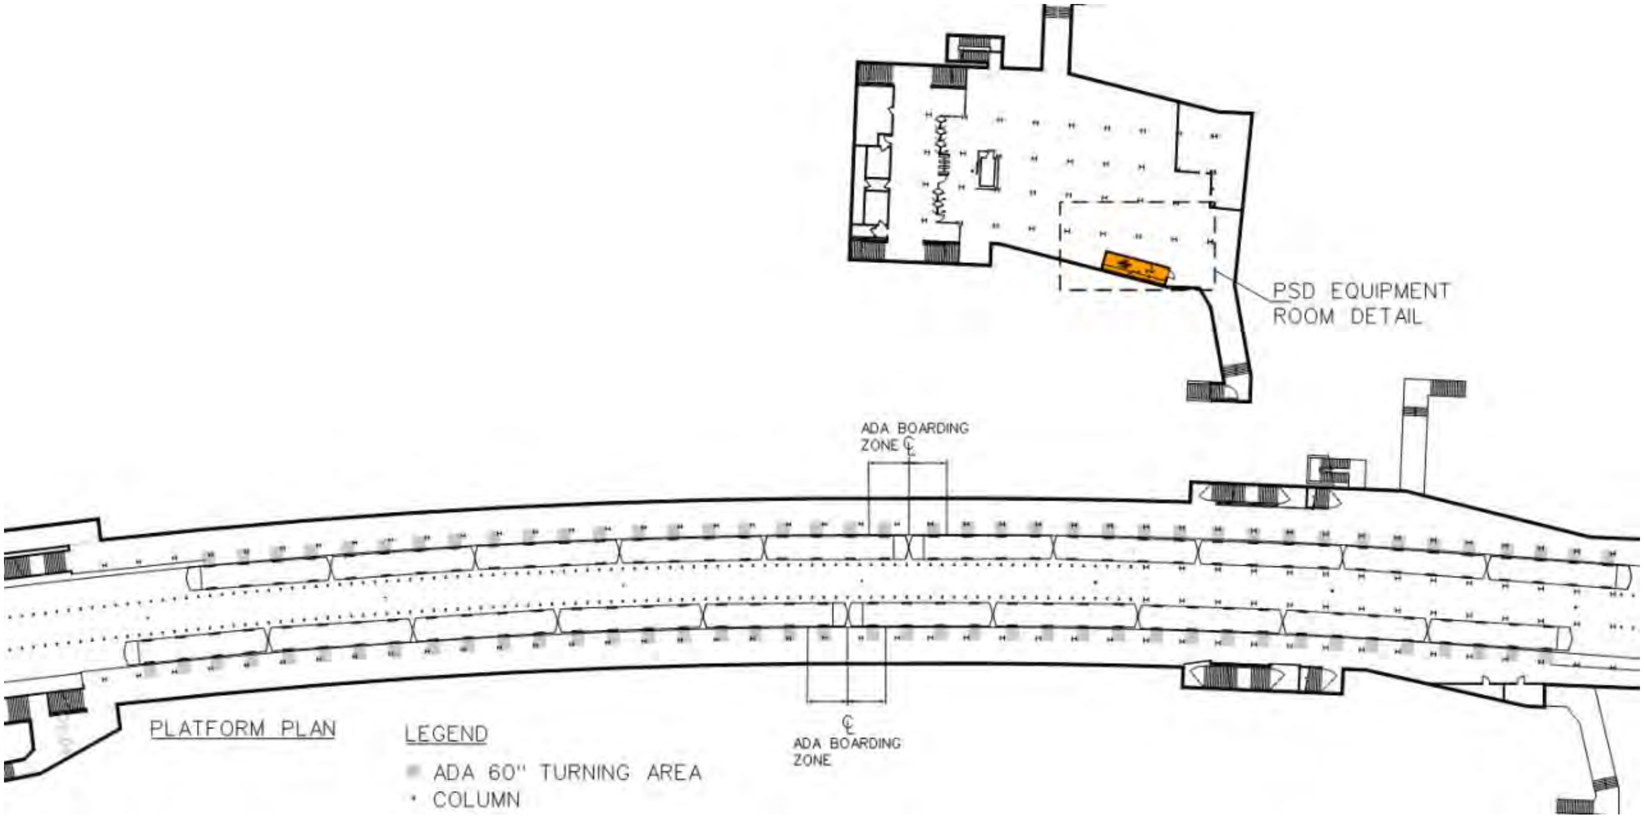

***Figure 1** – Overall plan*

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'D' Line Stations
(174th - 175th Street Station)

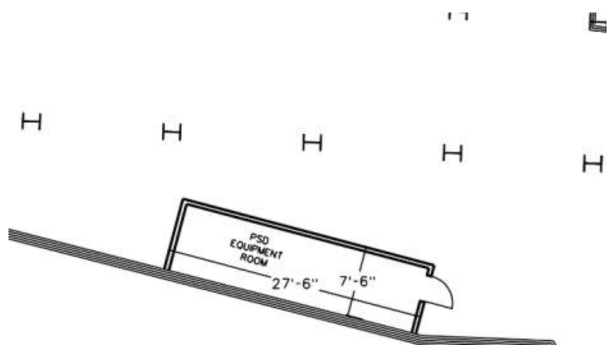

Figure 2 *– PSD Equipment Room Detail*
174th - 175th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear LED fixtures mounted parallel to the platform edge but inboard of the columns. No alterations to the existing lighting configuration are anticipated.

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.2M to install APGs and $40.6M to install PSDs (See Appendix E)

1.31 –MR 217 | 170th Street Station

Summary: *170th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

170th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-4" throughout. The platforms are straight with one row of columns approximately 3'-4" from edge of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and 1'-8" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
170th Street

1.32 –MR 218 | 167th Street Station

Summary: *167th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 167th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform widths vary from approximately 11'-4" to 13'-8". There are columns evenly distributed along the platform edge measuring 3'-4" from the platform edge. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting

Equipment Room

The equipment room can be located at the center of the station mezzanine (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

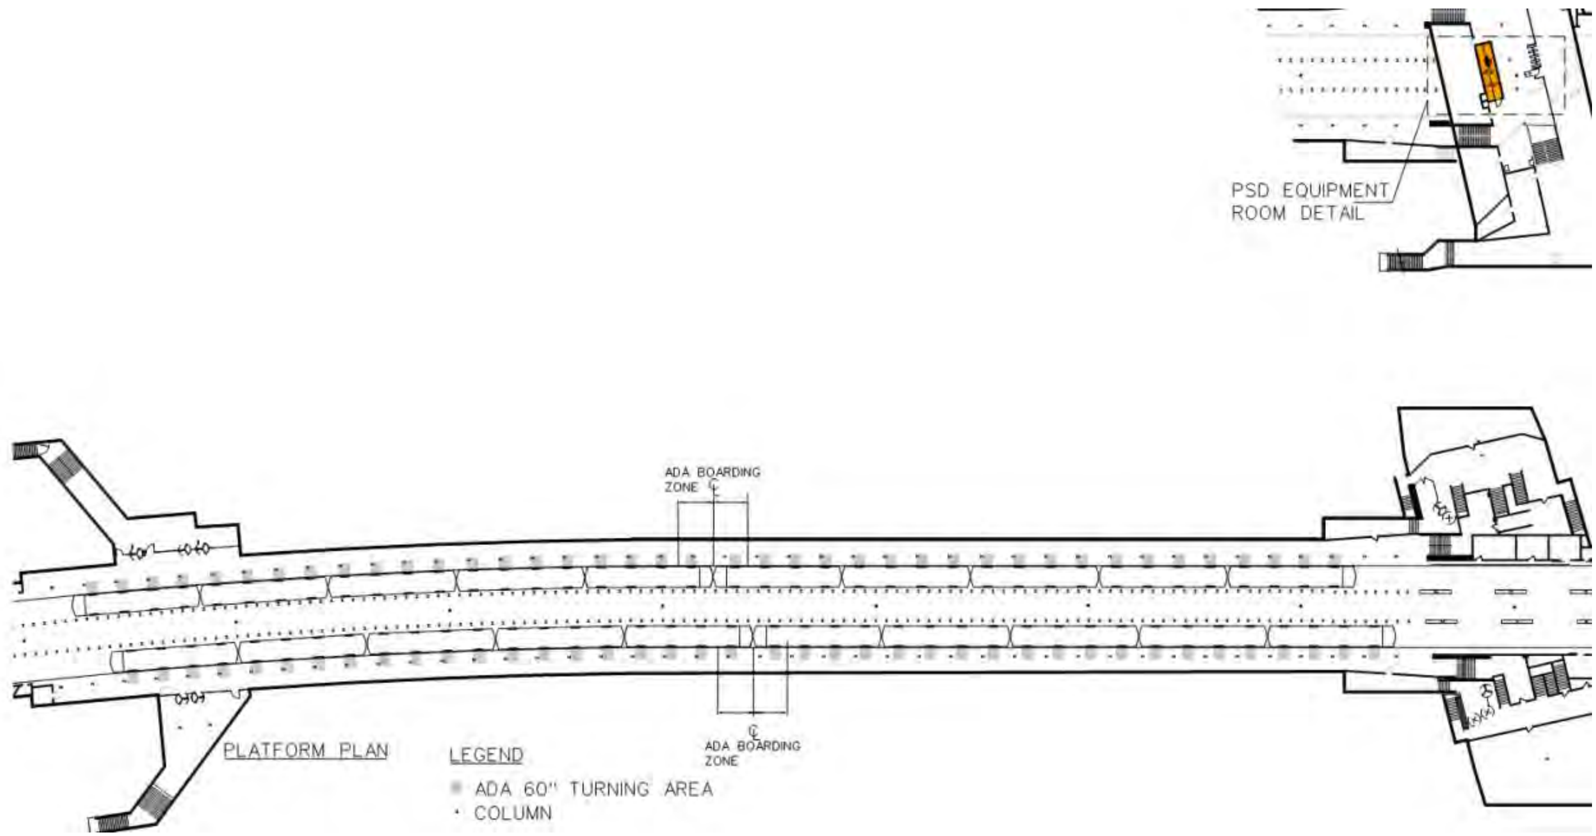

Figure 1 *– Overall plan*
167th Street Station

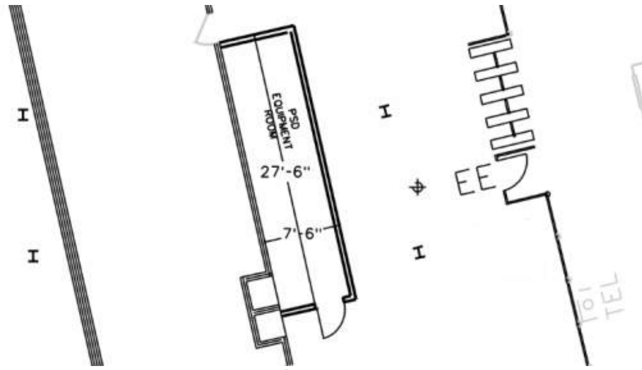

Figure 2 *– PSD Equipment Room Detail*
167th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear LED fixtures mounted parallel to the platform edge but inboard of the columns. No alterations to the existing lighting configuration are anticipated.

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	167th Street
Peak Demand Load from ConEd Report, (kW)	87.8 (combined)
Apparent Power (kVA)	109.8
Station Peak Demand Load, Max Current, (A)	304.9
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	499.5
Station Service Power Capacity,(A)	800
Service Spare Capacity, (A)	301
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 800A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combined for both Normal & Reserve.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.9M to install APGs and $40.1M to install PSDs (See Appendix E)

1.33 –MR 219 | 161st Street Yankee Stadium Station

Summary: *161st Street Yankee Stadium Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met on the northbound platform as the remaining width would be 27" (see figure 1).*

Description

161st Street Yankee Stadium Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-4" throughout. The platforms are straight with one row of columns approximately 3'-6" from edge of platform. At the northern end of the northbound platform, the columns measure 3'-6" from the platform edge and 1'-8" from a vent wall. The implementation of a platform edge barrier would reduce the currently compliant width of 42" to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
161st Street Yankee Stadium Street

1.34 –MR 220 | 155th Street Station

Summary: *155th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 23" (see figure 1).*

Description

The 155th Street Station is a below grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-4" throughout. The platforms are straight with one row of columns approximately 3'-2" from edge of platform. At the platform staircases, the columns measure 3'-2" from the platform edge and 1'-4" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 38" to 23" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

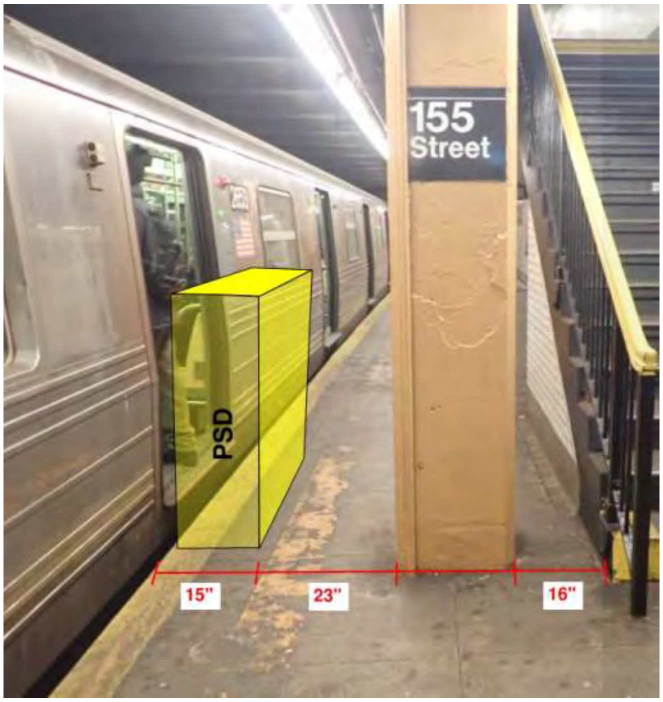

***Figure 1 –** Area of ADA non-compliance*
155th Street Station

1.35 –MR 231 | Grand Street Station

Summary: *Grand Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1).*

Description

The Grand Street Station is a below grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 8'-8" throughout. The platforms are straight with one row of columns approximately 3'-6" from edge of platform. At the platform staircases, the columns measure 3'-6" from the platform edge and 1'-8" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 42" to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

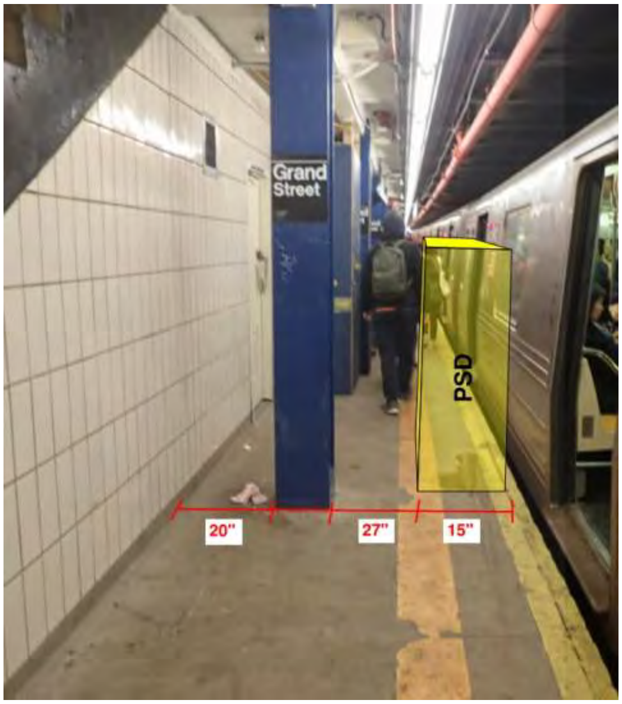

Figure 1 – *Area of ADA non-compliance*

1.36 –MR 277 | 7th Avenue Station (Manhattan)

Summary: *7th Avenue Station is feasible for both APGs and PSDs. There are four ceiling mounted signals located at the lower platform edges which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

7th Avenue Station is a below-grade station with two levels of center / island platforms **(see Figure 1)**. The B train utilizes the south side of both the upper and lower platform. The platform structures are cast-in-place concrete. At the upper level platform, column faces are typically 5'-4" from the platform edge and the platform measures 29'-4" wide throughout. At the lower level platform column faces typically measure 2'-8" from the Queens-bound platform edge and 3'10" from the Uptown-bound platform edge. The platform width varies from 13'-0" to 24'-8". On the lower platform there are four ceiling mounted signals located above the platform edge, measuring no less than 7'-4" above the ground. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the western end of the upper level platform adjacent to staircase P9 and at the center of the lower platform (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimension are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would at a minimum be required for the installation of an APG system.

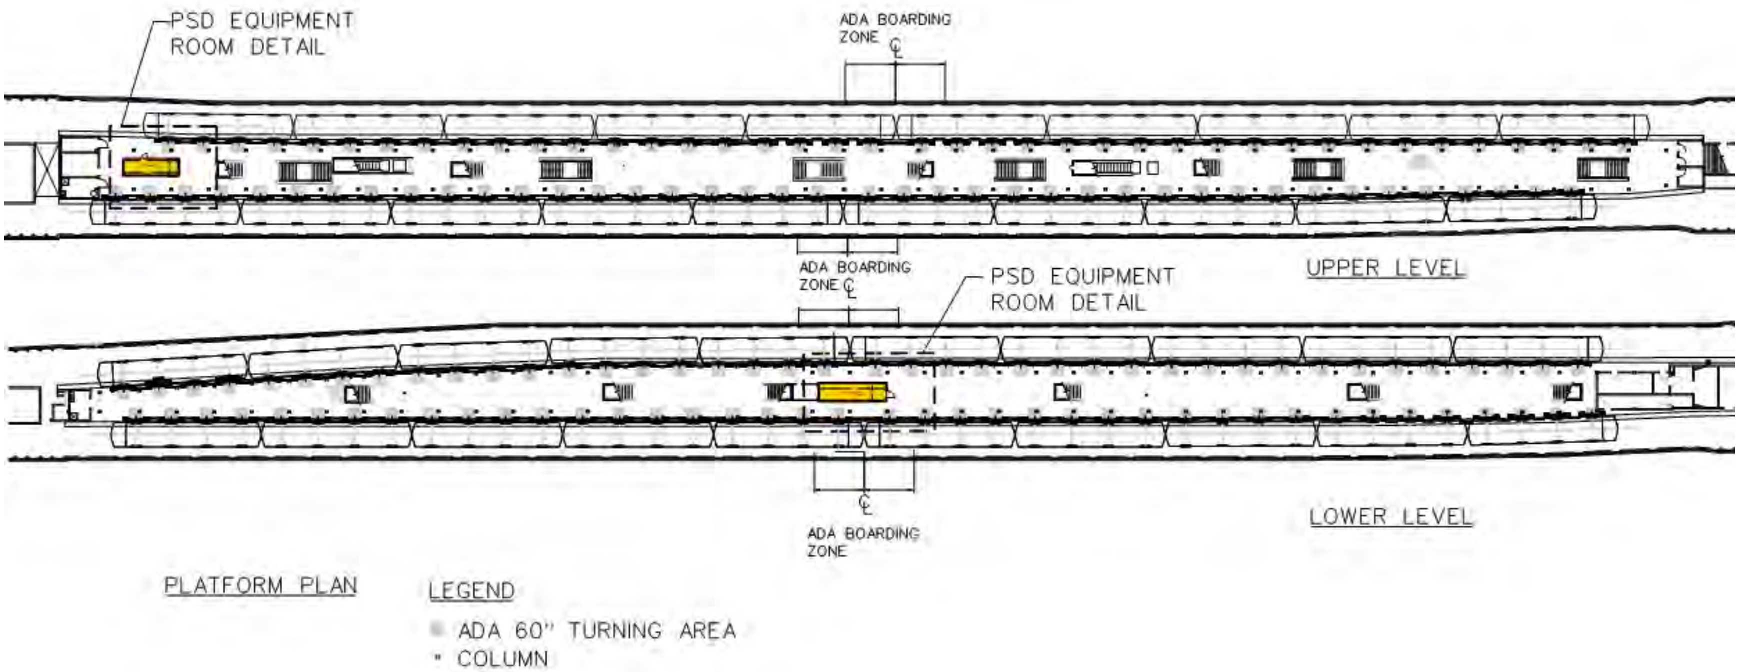

***Figure 1** – Overall Station Plan*
7th Avenue Station

7th Avenue Station

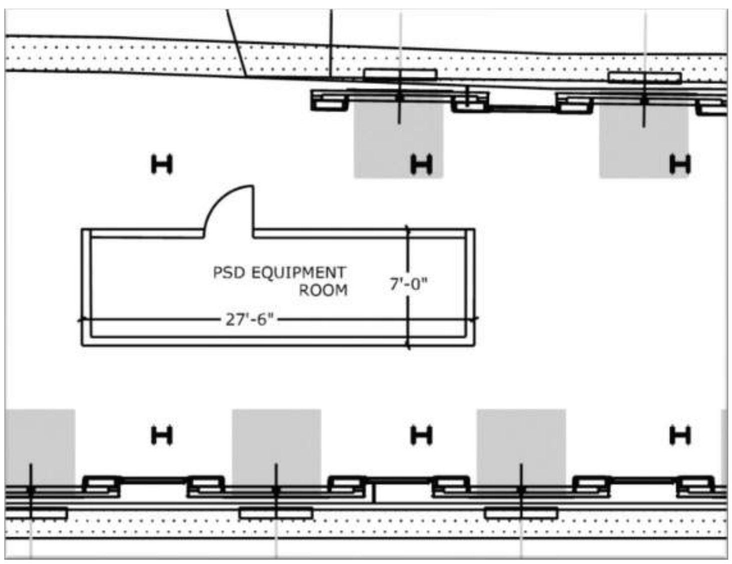

Figure 3 – PSD Equipment Room 2 Detail
7th Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 and 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal service)

Station Name	7th Avenue
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	76.8
Apparent Power (kVA)	96.0
Station Peak Demand Load, Max Current, (A)	266.7
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.8
Total Load (Station Peak + PSD), (A)	607
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	193
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter reading, for each Normal & Reserve service.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

1.0 *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*

1.1 *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*

1.2 *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*

- *a. Column location in relation to the platform edge*
- *b. Platform edge clearance adjacent to stairs and other impediments*
- *c. Impacts to ADA path of travel and boarding areas*
- *d. Conflicts of PSD/APG/RPSDs with Signals cables*
- *e. Sufficient platform width*
- *f. Extreme non-tangent track*

1.3 *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*

- *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
- *b. Feasibility & location for PSD/APG/RPSDs equipment room*
- *c. Confirmation of adequate power for PSD/APG/RPSDs*
- *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
- *e. Determination of communications requirements, availability and cost*
- *f. Determination of gap detection and entrapment avoidance technology requirements*
- *g. Determination of light fixture or other conflicts due to existing conditions*

1.4 *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*

1.5 *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

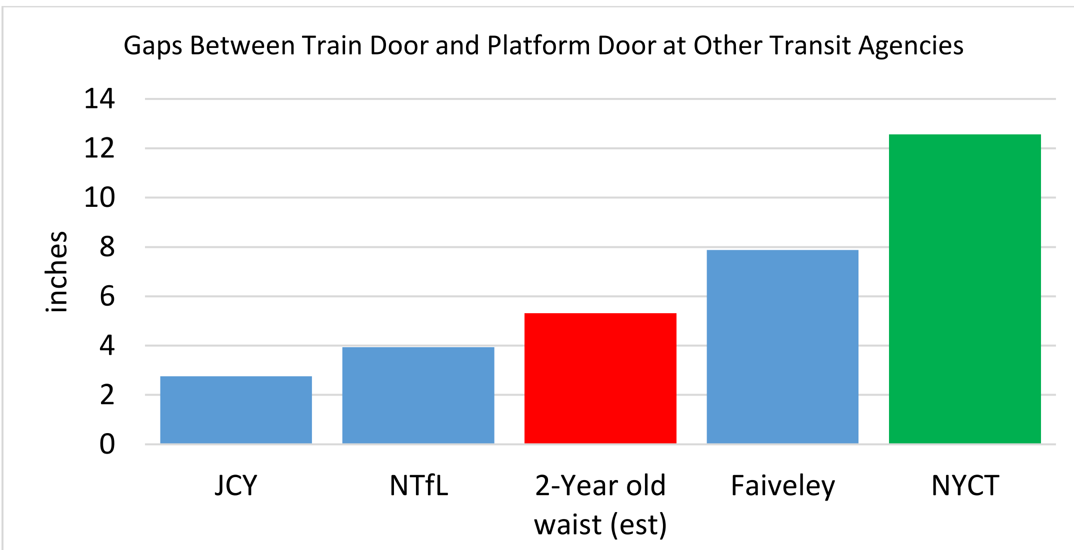

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

 *Figure 3 - Paris: no entrapment detection*	 *Figure 4 - Paris: no entrapment detection*	 *Figure 5 - France ATO: no entrapment detection*
 *Figure 6 - Paris, on curve: used 3 2D scanning lasers per door*	 *Figure 7 - Shanghai: End of platform light detection*	 *Figure 8 - Seoul: Platform observers*

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

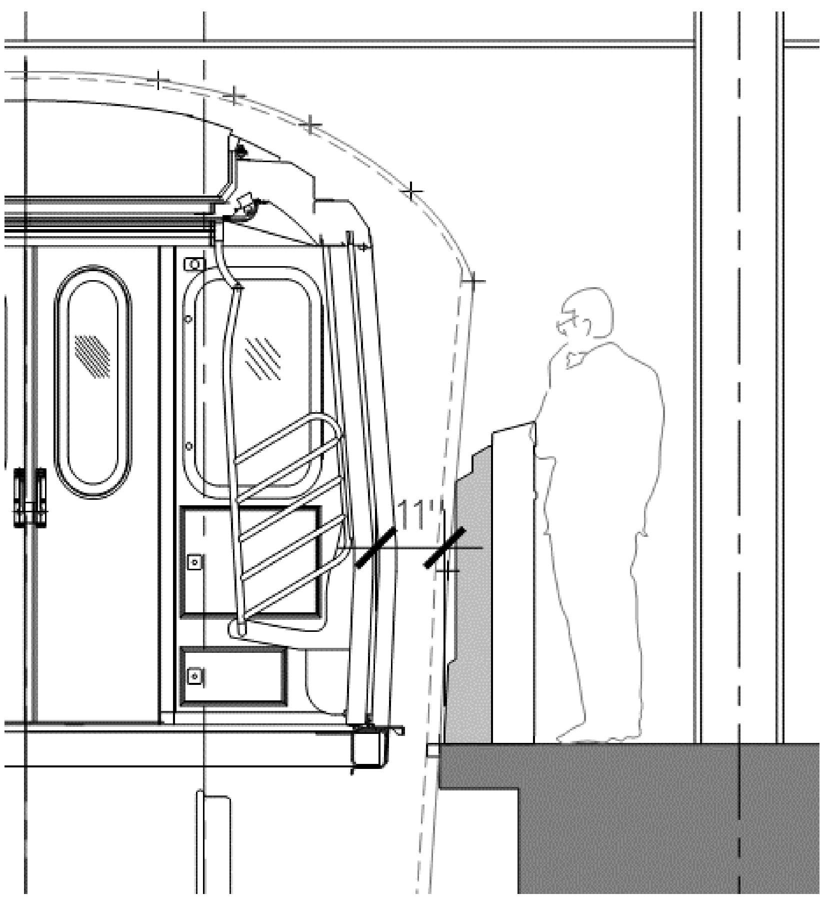

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

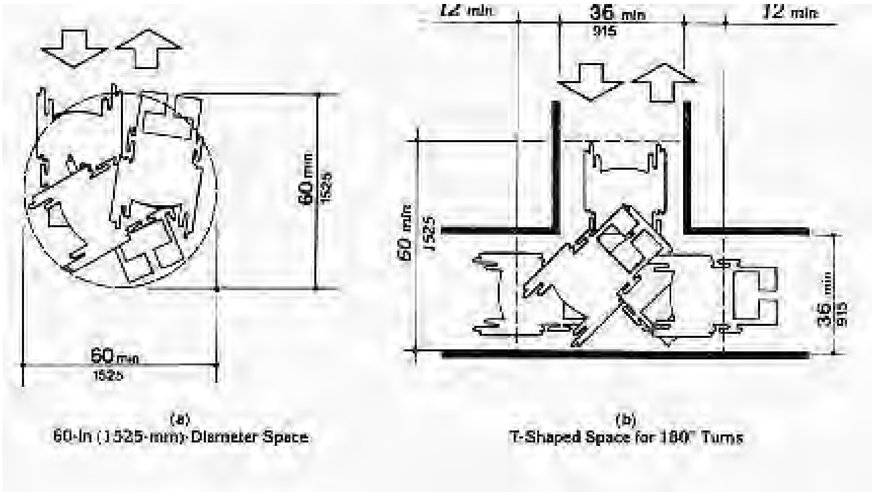
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

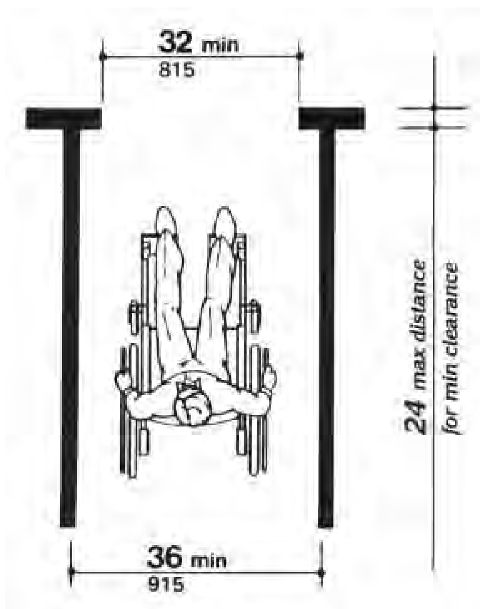


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as “existing”; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60” turning radius in which to make this turn. (the “T” shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an “alteration to the path of travel”, requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32” point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

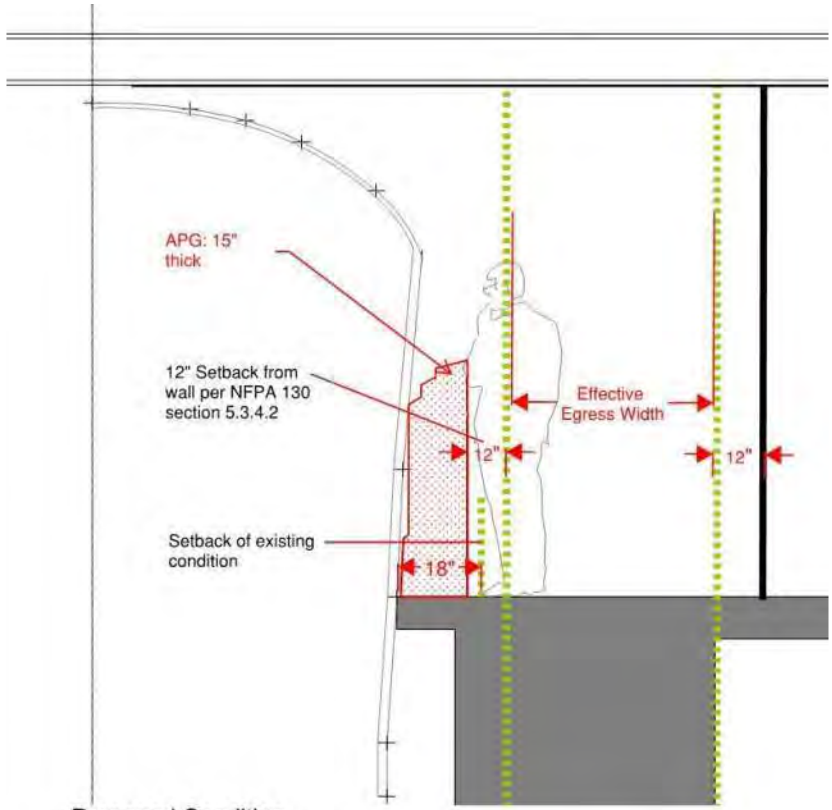
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents

Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.

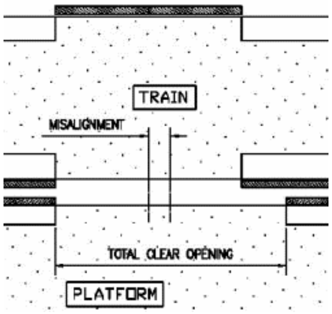
Appendix Table of Contents

Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Table of Contents
Appendix Table of Contents

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

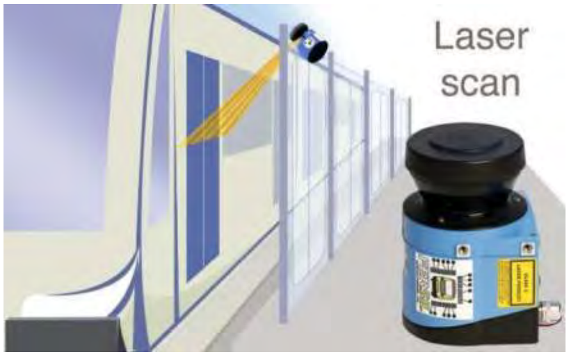
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

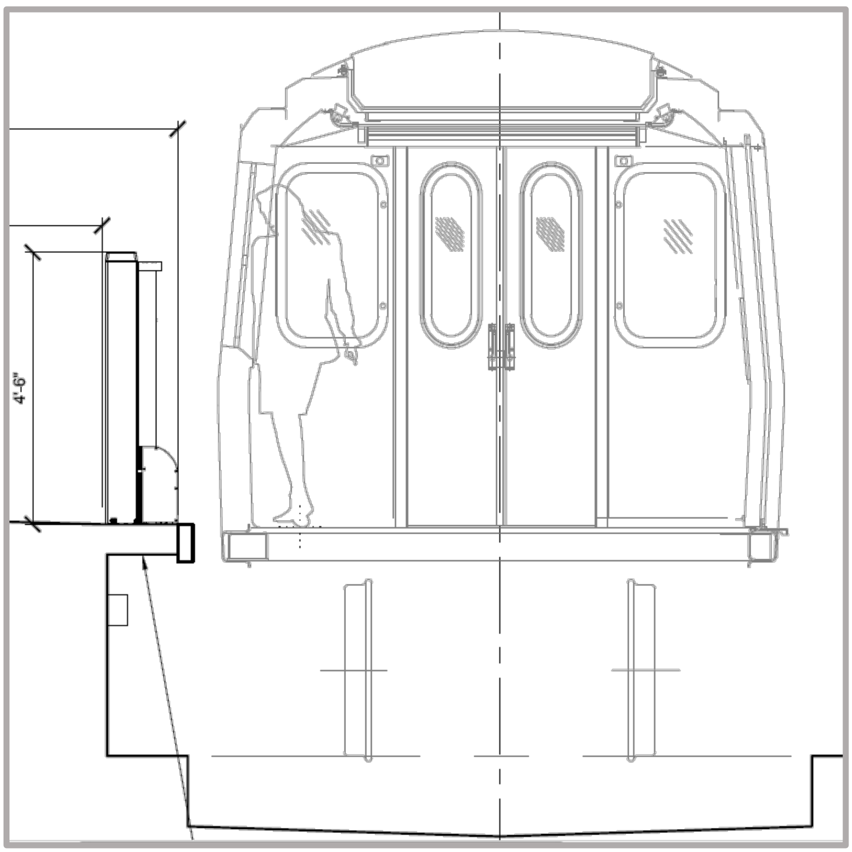


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

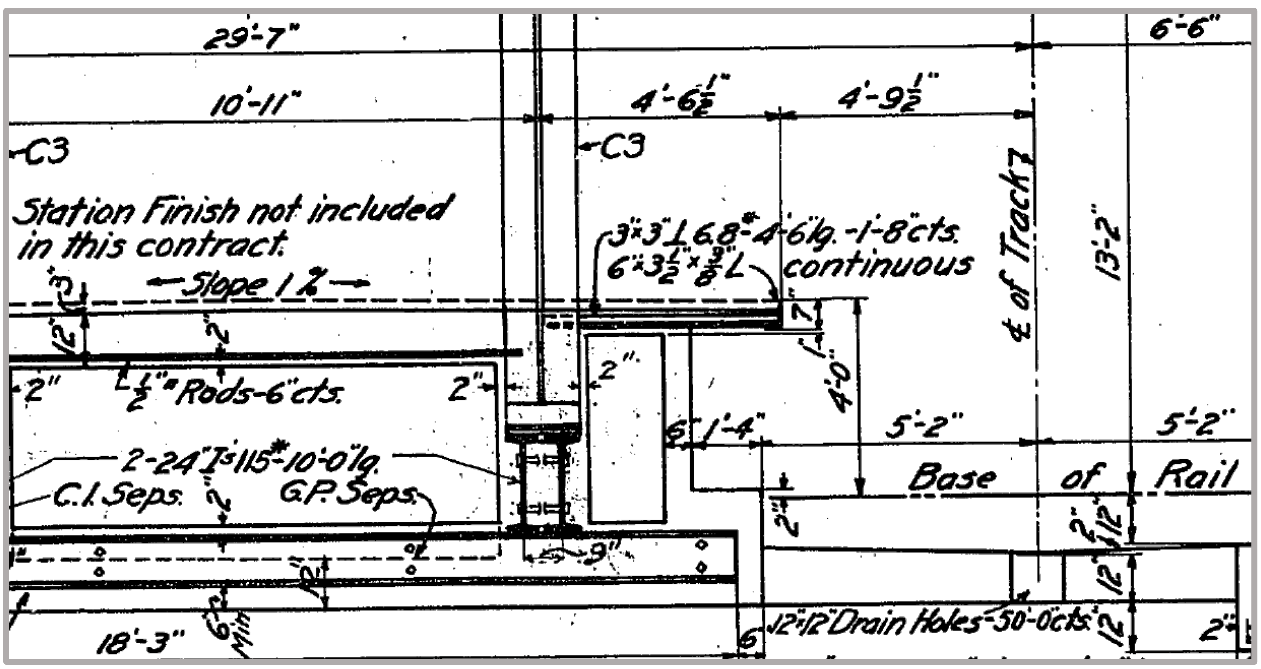

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

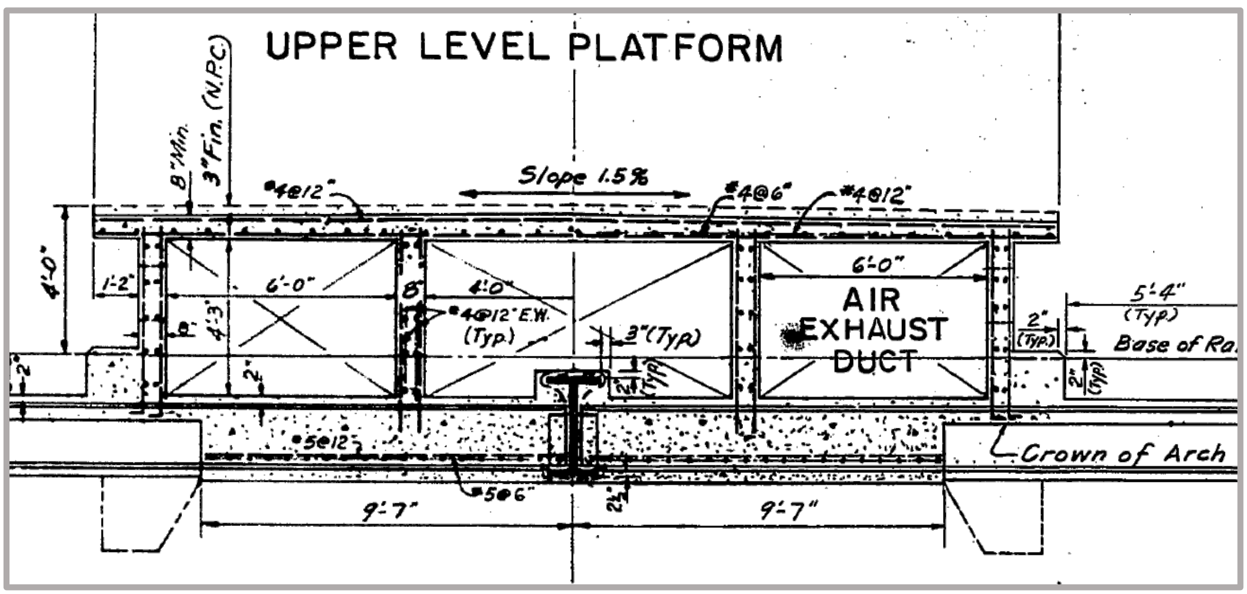

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

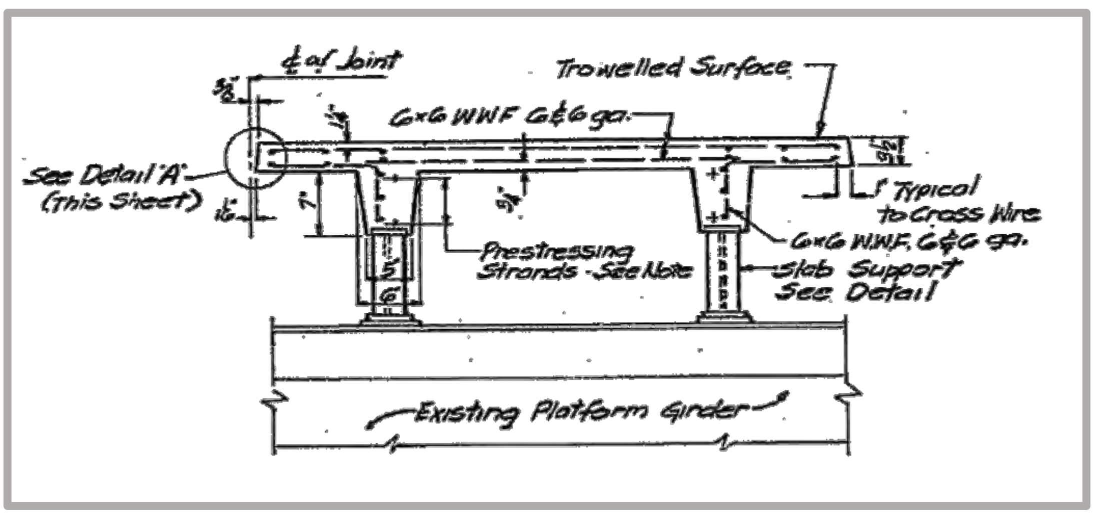

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

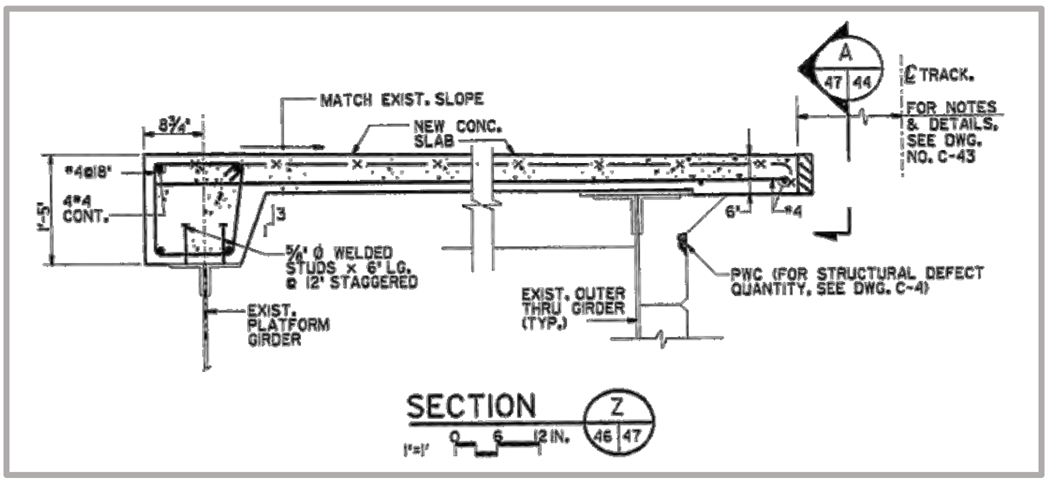

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

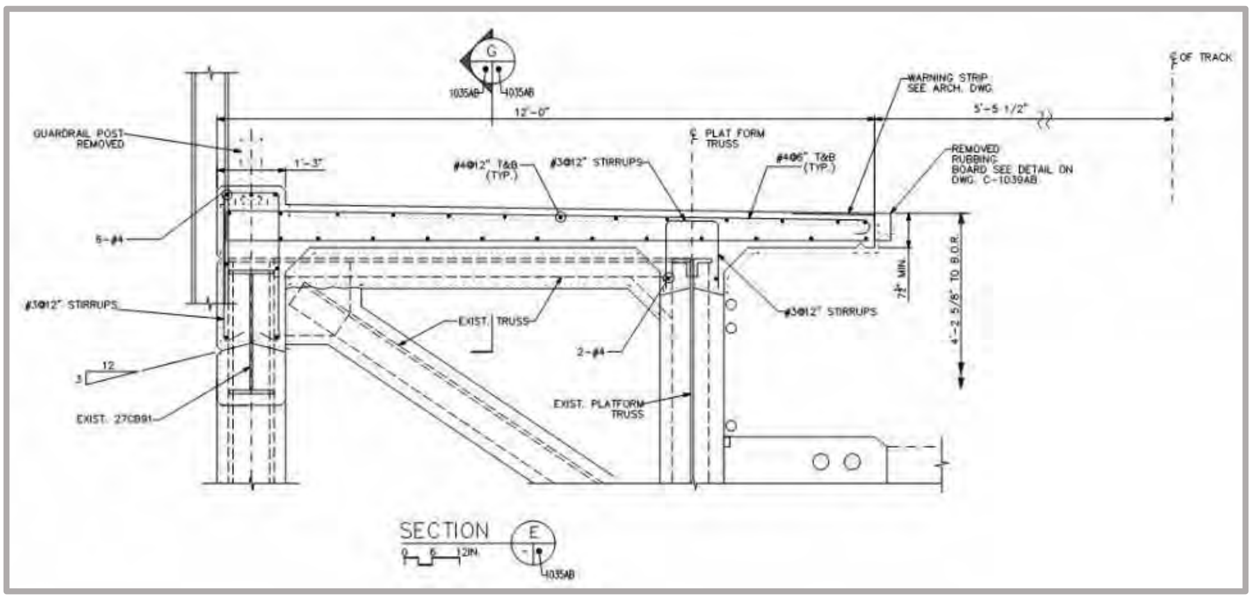

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

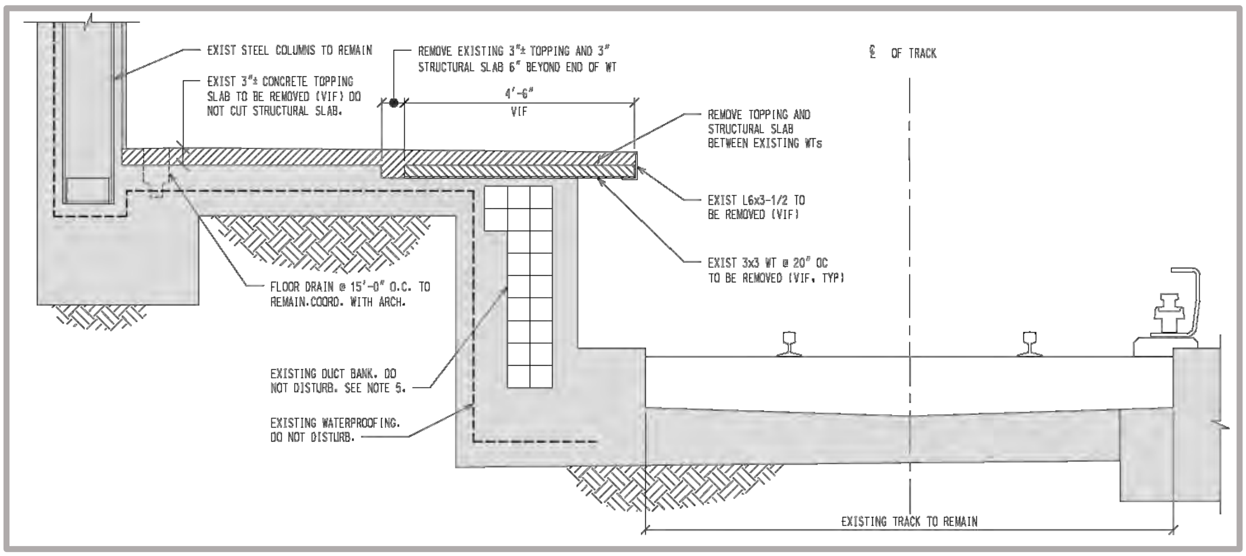

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

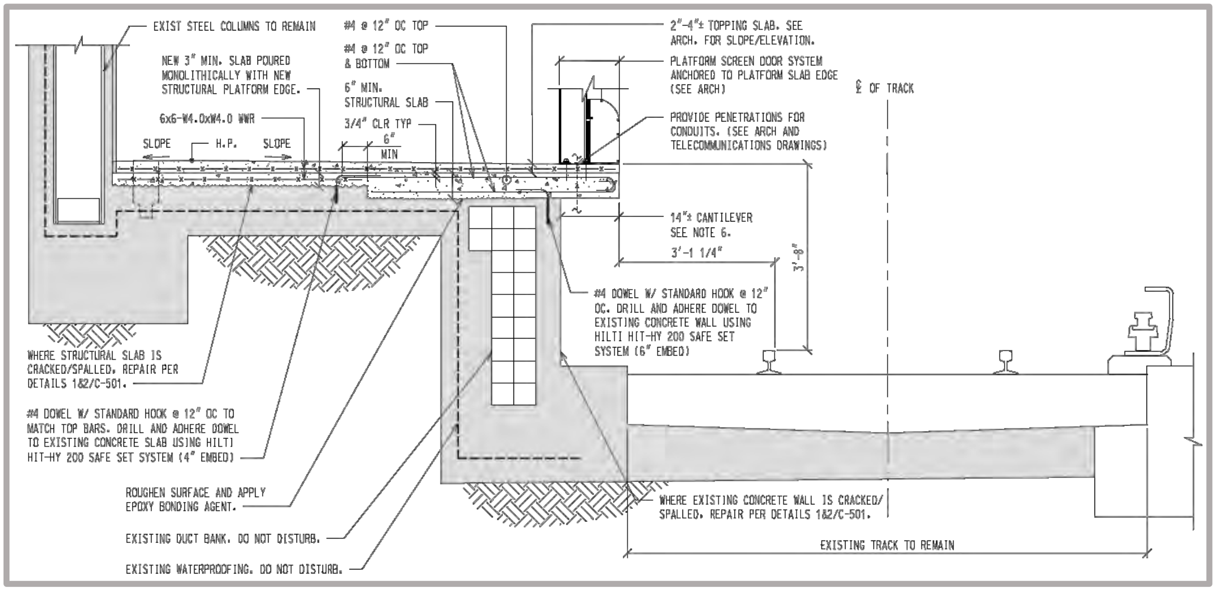

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

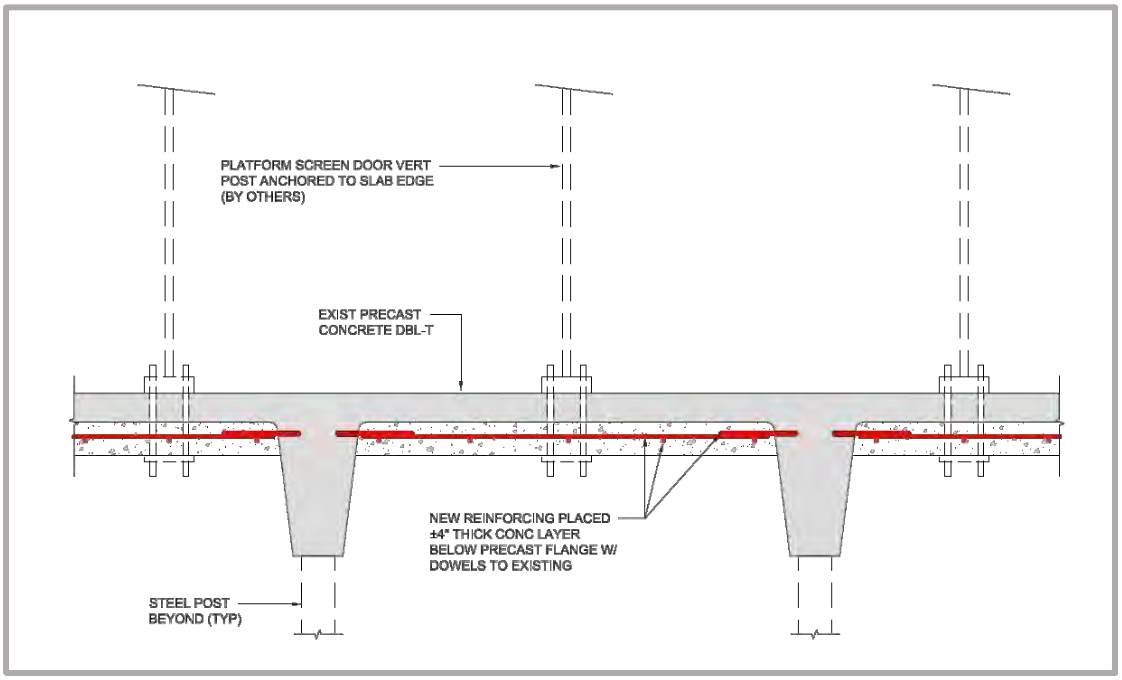

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

MTA/NYCT

June 3, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

MTA/NYCT

June 3, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or “soft” costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	618	LF		
5	LENGTH OF THE PLATFORM EDGE =	618	LF

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

3-Jun-19

STATION : 125TH ST. NICHOLAS AVE.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	634	LF		
5	LENGTH OF THE PLATFORM EDGE =	634	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,268**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,268	LF	7	8,876
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,340	SF	12	76,080
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	128	CY	2,500	320,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,270	EA	25	31,750
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,270	EA	25	31,750
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,268	LF	95	120,460
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,268	LF	15	19,020
26	Remove existing platform tiles	1,268	LF	12	15,216
27	Sawcut existing topping concrete at perimeter of removal area	1,268	LF	5	6,340
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,608	SF	8	60,864
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 7'-0" wide	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,268	SF	15	19,020

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

3-Jun-19

STATION : 174TH 175TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	671	LF		
5	LENGTH OF THE PLATFORM EDGE =	671	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,342**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,342	LF	7	9,394
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,710	SF	12	80,520
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	135	CY	2,500	337,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,344	EA	25	33,600
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,344	EA	25	33,600
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,342	LF	95	127,490
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,342	LF	15	20,130
26	Remove existing platform tiles	1,342	LF	12	16,104
27	Sawcut existing topping concrete at perimeter of removal area	1,342	LF	5	6,710
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,052	SF	8	64,416
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 8'-7" wide	687	SF	8	5,493
30	New Work				
31	New concrete topping to match existing	1,342	SF	15	20,130

3-Jun-19

STATION : 174TH 175TH ST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,342	LF	60	80,520
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	250	LF	60	15,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	300	LF	60	18,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

3-Jun-19

STATION : 167TH ST

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	659	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	659	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,318**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,318	LF	7	9,226
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,590	SF	12	79,080
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,320	EA	25	33,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,320	EA	25	33,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,318	LF	95	125,210
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,318	LF	15	19,770
26	Remove existing platform tiles	1,318	LF	12	15,816
27	Sawcut existing topping concrete at perimeter of removal area	1,318	LF	5	6,590
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,908	SF	8	63,264
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 5'-9" wide	460	SF	8	3,680
30	New Work				
31	New concrete topping to match existing	1,318	SF	15	19,770
32	New concrete topping at ADA boarding area to match existing	460	SF	15	6,900

73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
74	Power to PSD Room from EDR including track crossing if needed	100	LF	60	6,000
75	Reserve power to PSD Room from EDR including track crossing if needed	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
79	MISC				
80	Testing and commissioning	1	LS	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for D - Line Stations

3-Jun-19

STATION : 7TH AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE [SOUTH BOUND] =	658	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	658	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,315**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,315	LF	7	9,205
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,575	SF	12	78,900
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,317	EA	25	32,925
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,317	EA	25	32,925
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,315	LF	95	124,925
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,315	LF	15	19,725
26	Remove existing platform tiles	1,315	LF	12	15,780
27	Sawcut existing topping concrete at perimeter of removal area	1,315	LF	5	6,575
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,890	SF	8	63,120
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,315	SF	15	19,725

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'F' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

SUBMITTAL DATE: December 19, 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 45 newly evaluated stations, 40 have been found to be not suitable for the installation of PSDs.

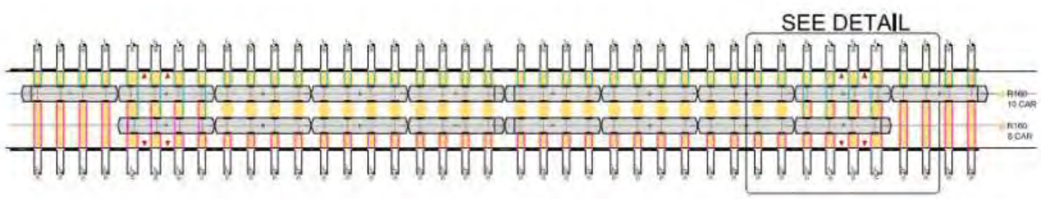
[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

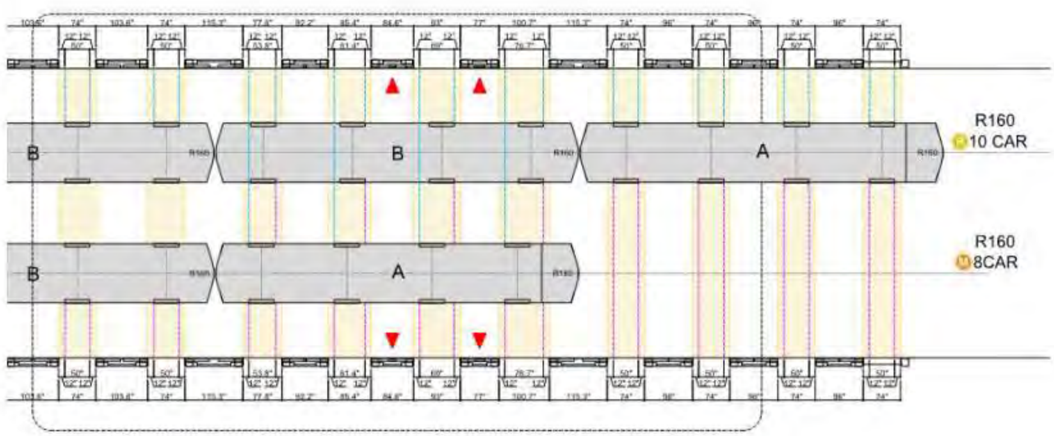
- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit. There are structural anomalies affecting the ability of platform edges to support PSD loads occurring at the three stations on the 63rd Street line as well as at three stations on the 6th Avenue line. These stations required a further structural analysis that can be found in the station specific reports.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the F-line service and an overlapping service on the B Division will remain incompatible even after 2032. The F is a ten-car train, whereas the M line is an eight-car train. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The M train cannot be extended to a ten-car length because all the station stops in Brooklyn feature station platforms of an eight-car length. Therefore, 17 of the 45 stations on the F-line are infeasible due to this incompatibility. Please see the diagrams in Figure 1 below.



Overall view of 10-car train versus 8-car train



Detail view of "A" car (with driver cabin) and "B" car. Sliding PSD doors cannot cover the wide openings required to cover both train door locations at the first two doors. A similar misalignment occurs at the rear of the train.

LEGEND
▲ SPACE BETWEEN DOOR OPENINGS IS INSUFFICIENT IN LENGTH TO ACCOMODATE SLIDING DOORS.

Figure 1 *– Ten-car vs. eight-car train Comparison of door geometry*

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the wall and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

Please note: Electrical capacity is not considered as a factor affecting feasibility in the installation of a future APG or PSD system in this study. Inadequate electrical capacity is observed as a factor that will increase the cost of installing a future APG or PSD system.

A garbage train is used for refuse removal on the 'F' Line. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 11% of the 'F' Line stations. Total implementation cost would be $159.2M for APGs and $202.1M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be $4,655,000.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'F' Line Stations

'F' Line Summary of Feasibility (11% feasible; 5/45)

No.	Station Name	Station Type	Platform Type	Feasible Yes / No	Issues / Reason for Failure	Cost APGs	Cost PSDs

1.0 Station Assessments

1.1 MR-254 | Jamaica-179th Street Station

Summary: *Jamaica-179th Street Station (MR-254) is not feasible for both APGs and PSDs. This station is not feasible because the implementation of a platform edge barrier would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" width requirement for ADA compliant wheelchair movement would not be met at all stairs. Remaining widths would be approximately 25" (see figure 1).*

Description

Jamaica-179th Street Station is a below-grade terminus station serving the E and F trains. The station has two straight center/island platforms that are slightly tapered at the south-end of the station. Both platforms have one track dedicated to F-train service. The cast-in-place concrete platforms are accessed via the mezzanine. There are five stairs on the northbound platform & six stairs on the southbound platform. The platforms are approximately 19'-6" wide, but taper to a narrow 7'-0" at the south-end of the platform. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not permit wheelchair movement along the length of the platform.

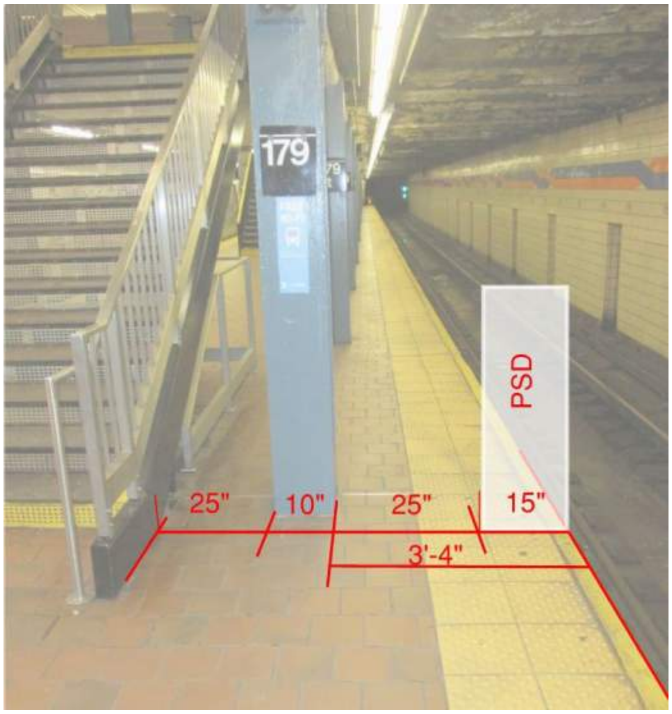

Figure 1 – Non-compliant ADA condition at stairs (typical)- Jamaica-179th Street Station

Table of Contents

1.2 MR-255 | 169th Street Station

Summary: *169th Street Station (MR-255) is not feasible for both APGs and PSDs as their implementation would create non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" width requirement for ADA compliant wheelchair movement would not be met at all stairs. Remaining widths would be approximately 25" (see figure 1).*

Description

169th Street Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of the side platforms are approximately 11'-4". Columns are spaced 15' on center and columns faces are 3'-4" from the edge of the platform. There is typically 2'-0" between the column and railing at all staircases. There are five staircases along each platform, all of which would not comply with the 32" width requirement for wheelchair movement. Columns divide the path between the stairs and the platform edge. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

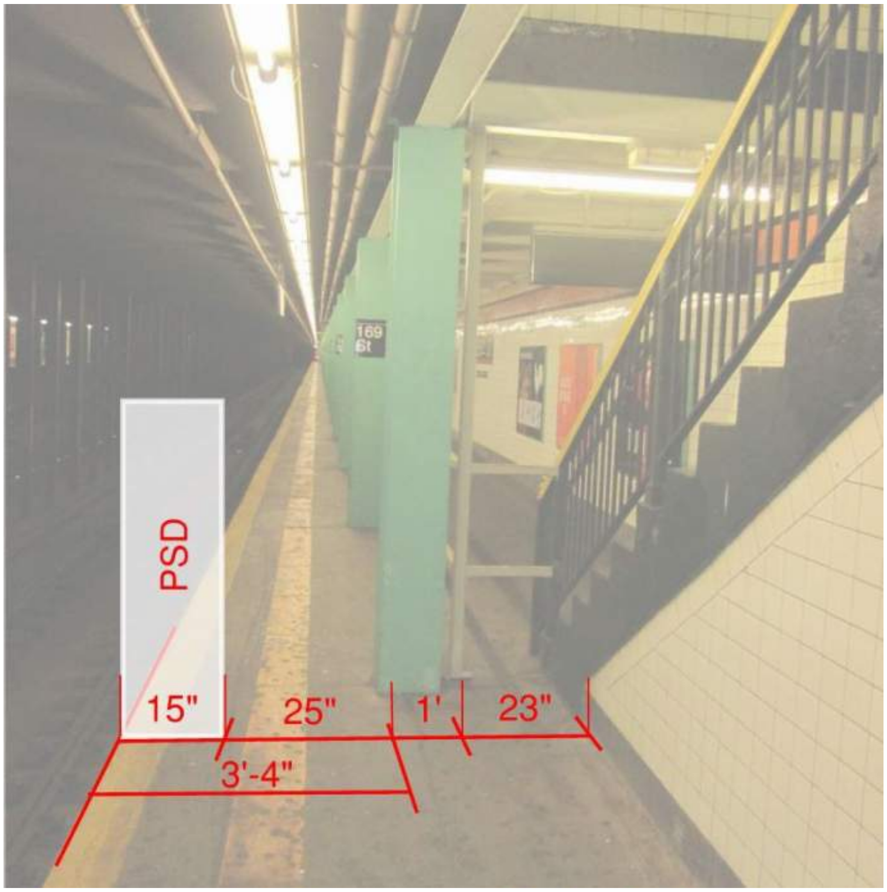

Figure 1 – Non-compliant ADA condition at stairs (typical)- 169th Street Station

1.3 MR-256 | Parsons Boulevard Station

Summary: *Parsons Boulevard Station (MR-256) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). This condition occurs at all stairs on the local track edge of both platforms.*

Description

Parsons Boulevard Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 19'-6". There are five staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-4" away from all platform edges. The stairs are not centered on the platform, but shifted towards the local track edges. These stair are flanked on one side by the typical station column (3'-4" from the platform edge). Typically, the stairs are 9' from the express platform edge. See figure 2 for typical edge conditions at local and express sides of the platform. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

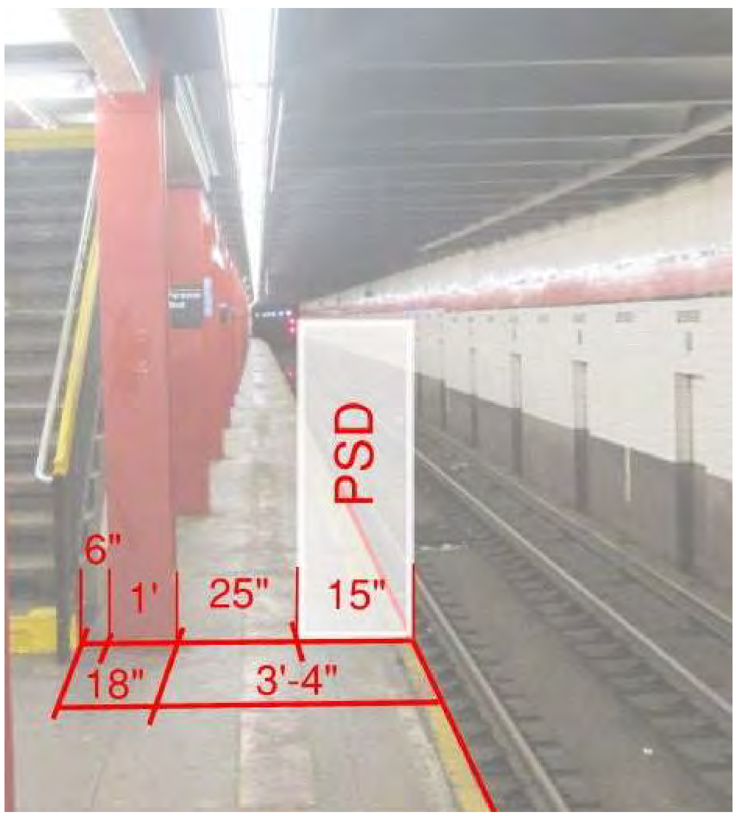

Figure 1 – Non-compliant ADA condition at stair (typical on local edge only) – Parsons Blvd. Station

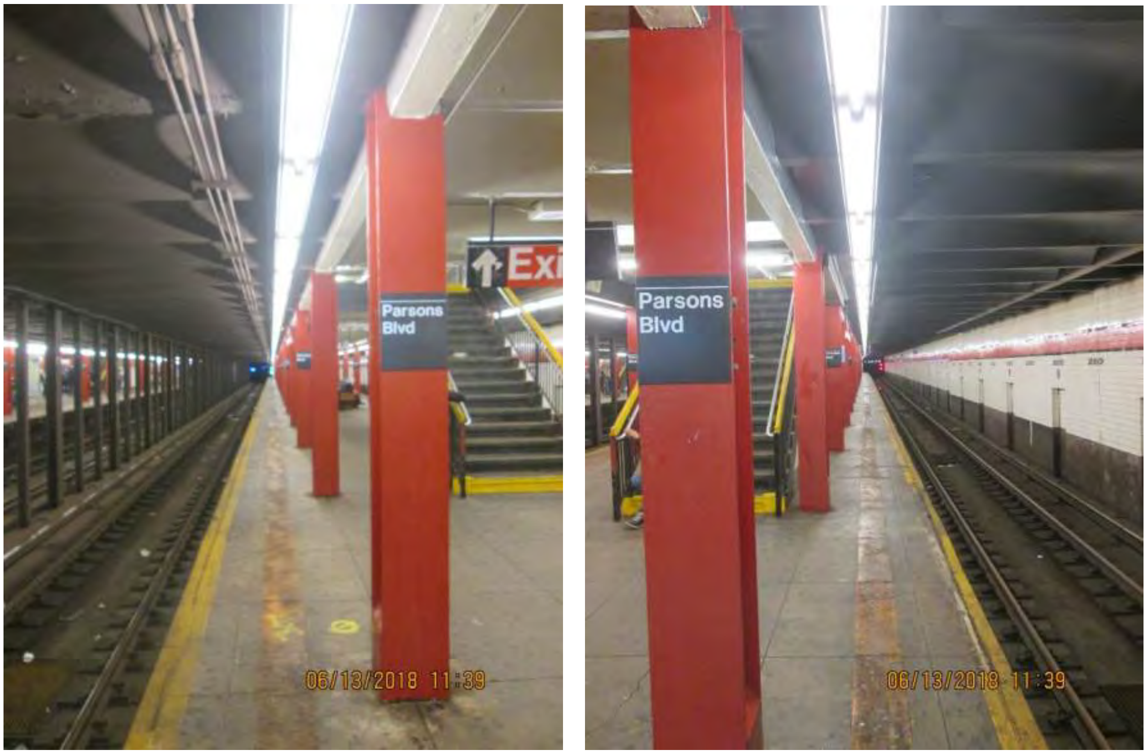

Figure 2 – Typical edge conditions | Express condition (left) and local condition (right)– Parsons Blvd. Station

1.4 MR-257 | Sutphin Boulevard Station

Summary: *Sutphin Boulevard Station (MR-257) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). This condition would occur at all stairs on both platforms.*

Description

Sutphin Boulevard Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 11'-4". There are six staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns divide the path between the stairs and the platform edge. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-4"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

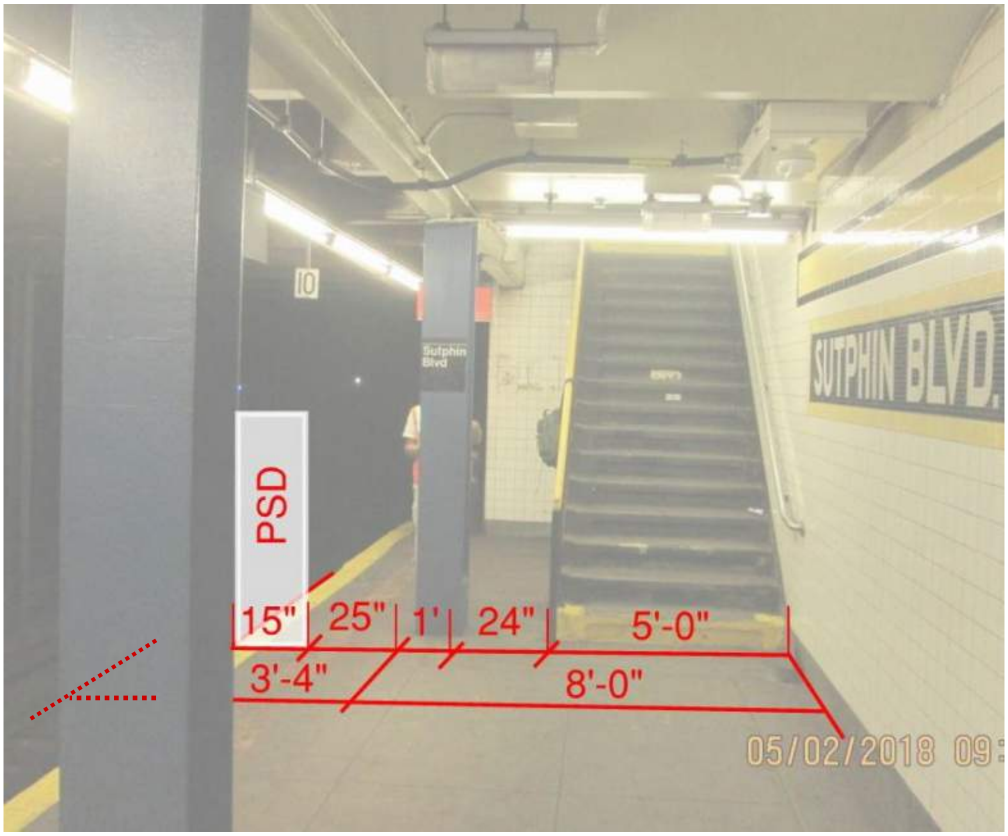

Figure 1 – Non-compliant ADA condition at stairs (typical)- Sutphin Blvd. Station

1.5 MR-258 | Briarwood Station

Summary: *Briarwood Station (MR-258) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 23" (see figure 1). This condition occurs at all stairs on both platforms.*

Description

Briarwood Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 11'-4". There are four staircases along each platform, all of which would not allow for the 32" width required for wheelchair movement with PSDs installed. Columns divide the path between the stairs and the platform edge. Column spacing along the length of the platform is approximately 15'-0" on center and column faces are typically 3'-2" to the edge of the platform. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-2"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 23" would not allow for ADA compliant wheelchair movement.

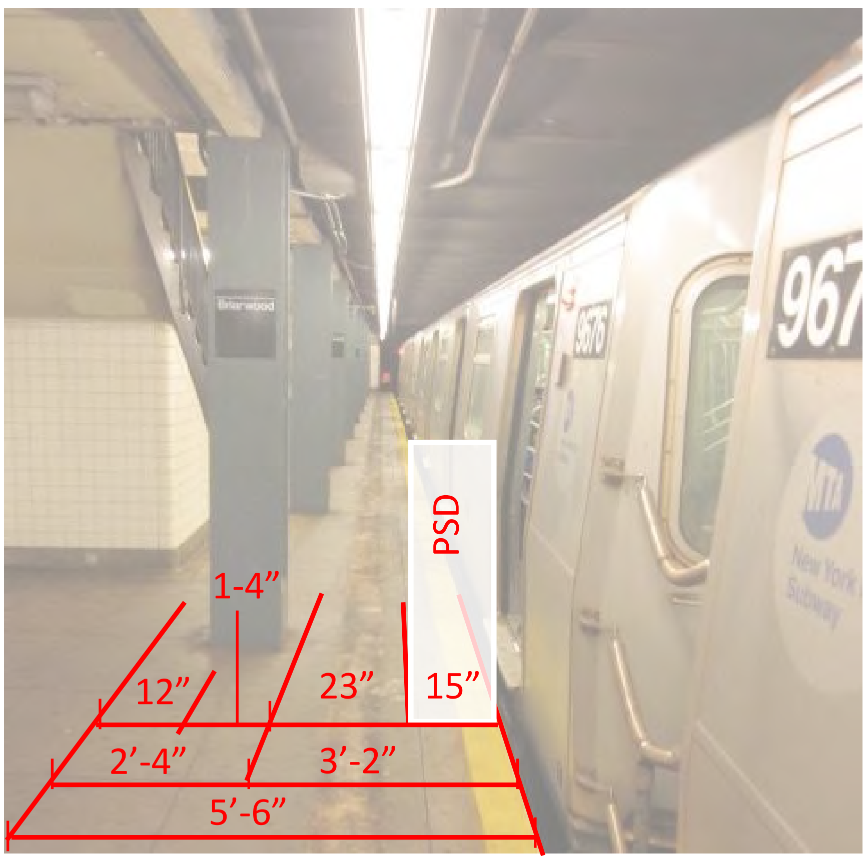

Figure 1 – Non-compliant ADA condition at stairs (typical)- Briarwood Station

1.6 MR-259 | Kew Gardens-Union Turnpike Station

Summary: *Kew Gardens-Union Turnpike Station (MR-259) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met on one side of the platform (see figure 1). The remaining width would be 24".*

Description

Kew Gardens-Union Turnpike Station is a below-grade station consisting of two mildly curved center/island platforms. The cast-in-place concrete platforms are accessed via two mezzanines. There are six stairs and an elevator located on each platform. The platform is approximately 19'-0" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-3" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-3"). All of the stairs are off center as shown in figure 1. Although there is adequate clear space on one side of the platform, the implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement at the other side. Similarly, the elevators are shifted towards one side of the platform not allowing for 32" clearance (at one platform edge) for ADA compliant wheelchair movement. Both platform edges need to comply in order for the station to be ADA compliant for the implementation of a platform edge barrier.

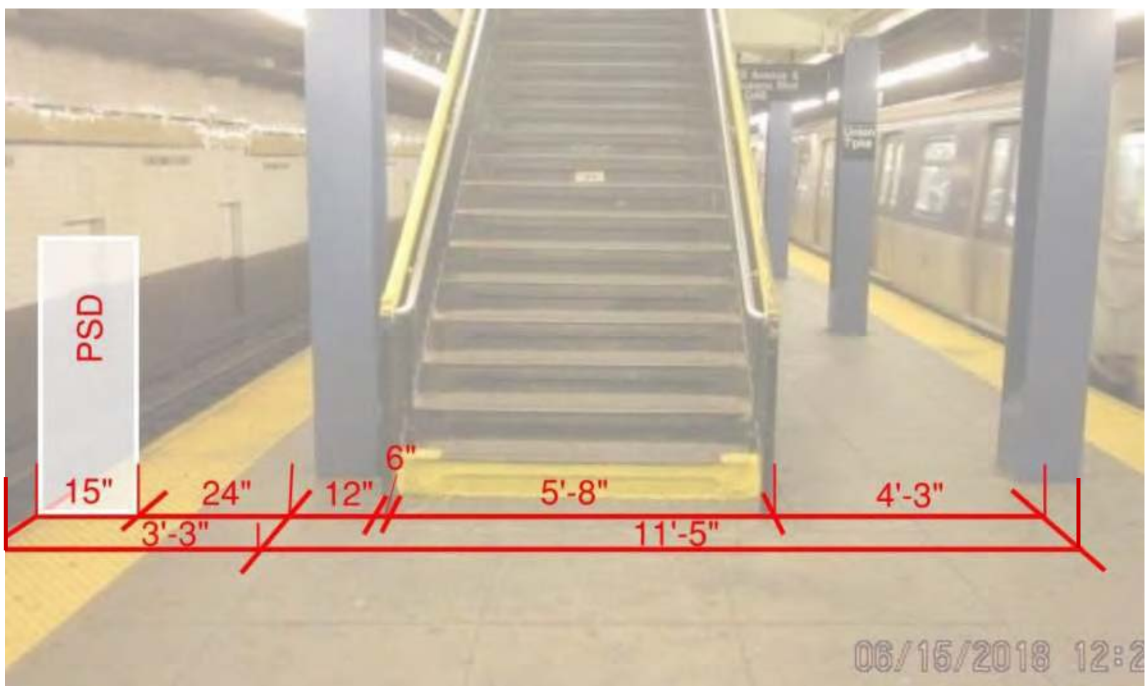

Figure 1 – Non-compliant condition on one side of the center/island platform- Kew Gardens-Union Turnpike

1.7 MR-260 | 75th Avenue Station

Summary: *75th Avenue Station (MR-260) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform. At all stairs, the 32" minimum requirement for wheel chair circulation would not be met (see figure 1).*

Description

75th Avenue Station is a below-grade station consisting of two straight side platforms. The cast-in-place concrete platforms are accessed via a large mezzanine level. There are four stairs located in various locations along the length of each platform. The platforms are approximately 11'-4" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Columns are 1'-10" away from stairs (not an ADA compliant path). Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). In the implementation of a platform edge barrier, this clearance would be 25".

Figure 1 – Non-compliant condition at stairs (typical) - 75th Avenue

1.8 MR-221 | 21st Street- Queensbridge Station

***Summary:** 21st Street-Queensbridge Station (MR-221) is feasible for both APGs and PSDs. There are two signal boxes that would have to be relocated in the implementation of a platform edge barrier. Structural work would only be required in the implementation of APGs (see structural report; Appendix B) Electrical capacity at this station is adequate to support a APG/PSD system.*

Description

21st Street-Queensbridge Station is a below-grade station with two straight side platforms (see figure 1). The platform structure is cast-in-place concrete. Back-of-house elements are located at the mezzanine level and at the platform level away from passenger areas. The platforms are mostly column free. On both platforms, there are five 2' wide cylindrical columns which are 7'-6" away from the platform edge. Typically, the platform widths are approximately 11'-2". These columns are in a double height space that is open to the mezzanine level. On each platform, one train signal box hangs over the platform edge, with a vertical clearance of 7'-4". Ceiling heights vary throughout the station, ranging from 9'-2" to 20'-0".

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling heights vary throughout the station (see figure 4). Train signal boxes on would need to be relocated in the implementation of full height PSDs (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the Coney Island-bound platform adjacent to the elevators. The proposed room dimension is 7'-0" x 27'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

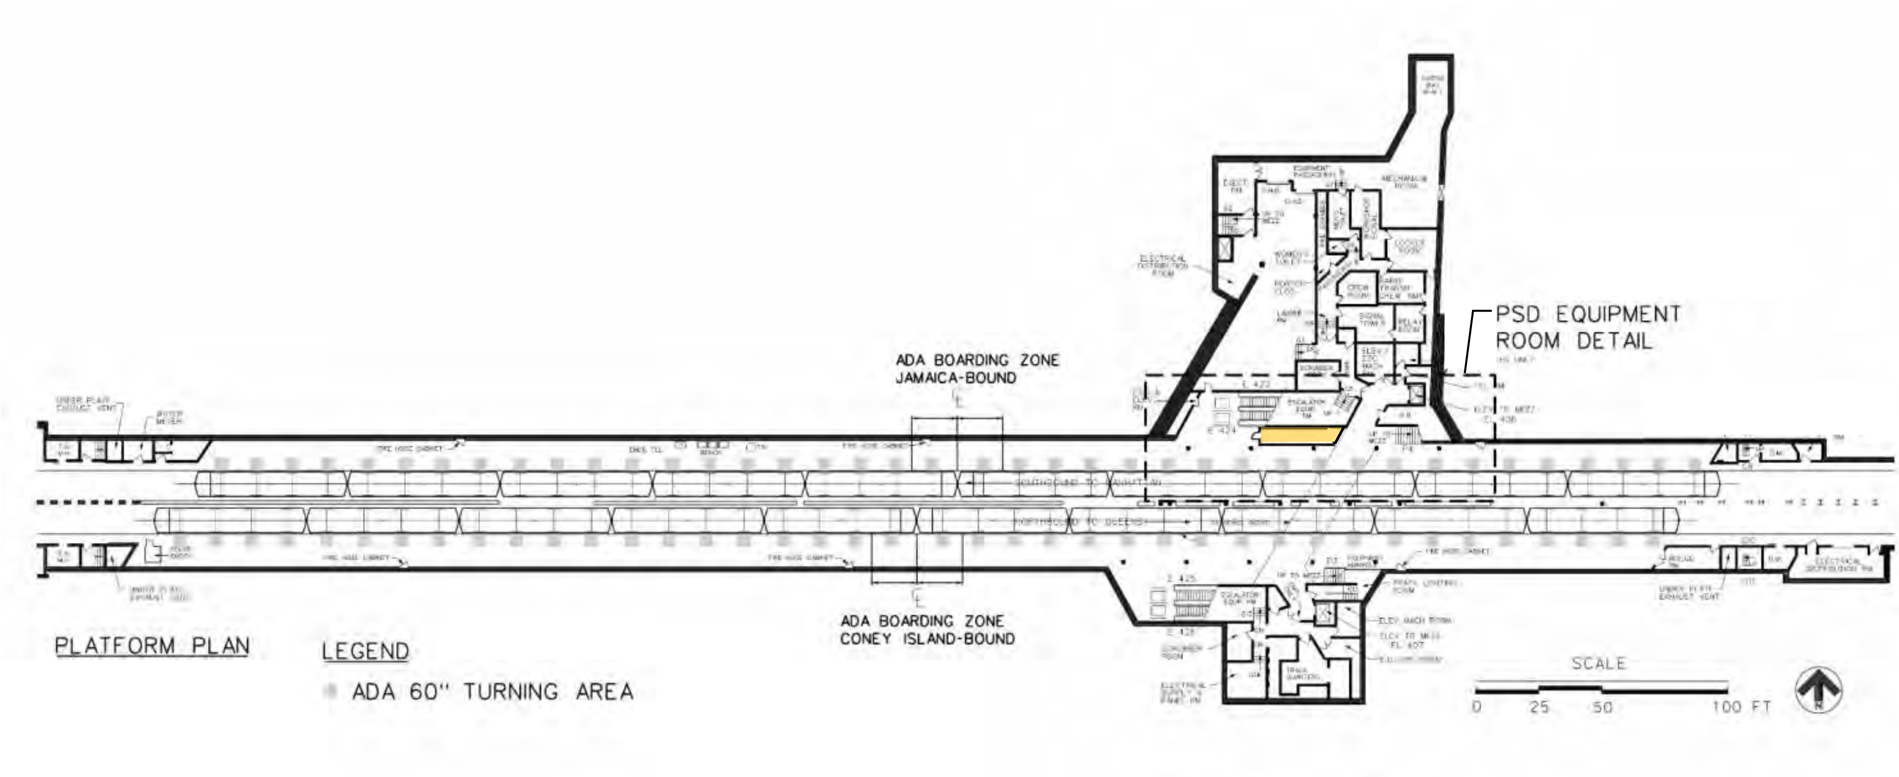

Figure 1 – Station Plan- 21st Street- Queensbridge Station

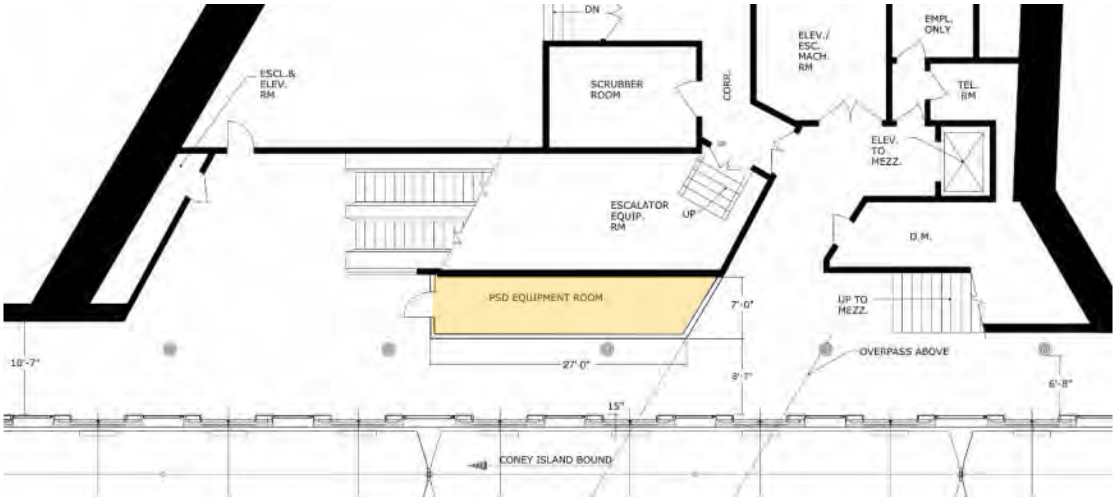

Figure 2 – PSD Equipment Room Detail – 21st Street- Queensbridge Station

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

The 2012 NYCT conditions survey gave the platform edges an average rating of 2.5. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

None

Lighting:

Existing lighting: Along the majority of the platform, linear florescent lighting is perpendicular to the platform edge and located between structural members. In the double height area, there are recessed florescent fixtures and can lighting. It is unlikely that the existing lighting would need to be modified at this station.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station. MRN 221 has adequate capacity to support the implementation of a APG/PSD system.

Station
Power Capacity Analysis

NYCT Station MR Number	221
Station Name	21st Street Queensbridge
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	404.0
Apparent Power (kVA)	505.0
Station Peak Demand Load, Max Current, (A)	1402.8
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	1597
Station Service Power Capacity, (Main SB or SG Rating), (A)	3000
Service Spare Capacity, (A)	1403
Is Electrical Service Adequate?	Yes
Notes	Station does not have 1 line diagram. This analysis is based on one meter reading only.

Table 1. MRN 221 Power Capacity Analysis

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $39.8M to install PSDs (See Appendix E)

Figure 3 – Typical platform view with signal box- 21st Street- Queensbridge Station

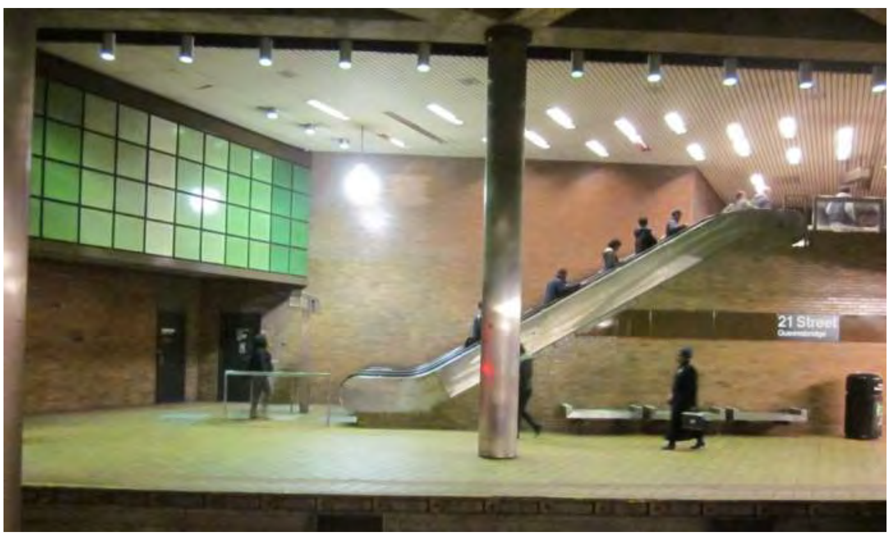

Figure 4 – View of double-height area - 21st Street- Queensbridge Station

1.9 MR-222 | Roosevelt Island Station

Summary: *Roosevelt Island Station (MR-222) is feasible for both APGs and PSDs. There are a variety of conditions in this station including curved or straight walls and ceilings, varying ceiling heights, and different lighting supports. Structural work would only be required in the implementation of APGs (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system.*

Description

Roosevelt Island Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Back-of-house elements are located at the end of the platforms and at the mezzanine level. The platforms are column free. Typically, the platform widths are approximately 12'-0". There are a variety of platform conditions, in which the platform is a combination of curved and/or straight walls and ceilings. Ceiling heights vary from 7'-10" to 12'-10". Figures 3 and 4 represent typical platform wall and ceiling combinations as well as various lighting conditions.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north-end of the Jamaica-bound platform. The proposed room dimension is 7'-0" x 27'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support

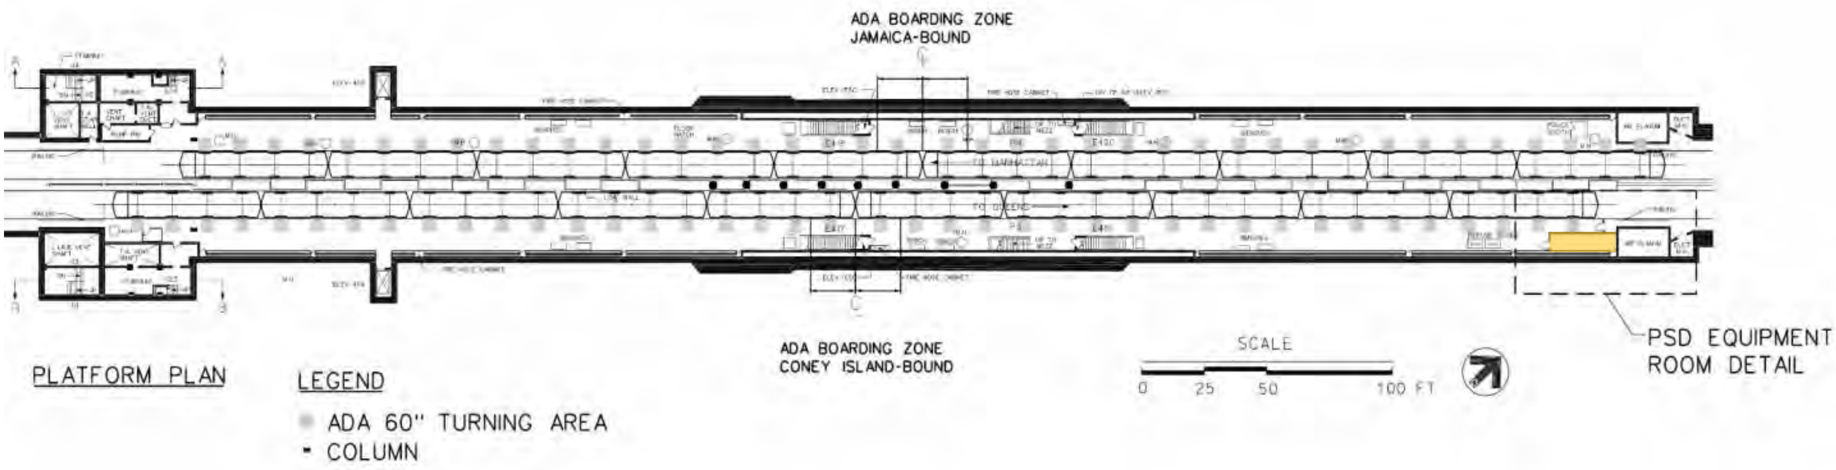

Figure 1 – Station Plan- Roosevelt Island Station

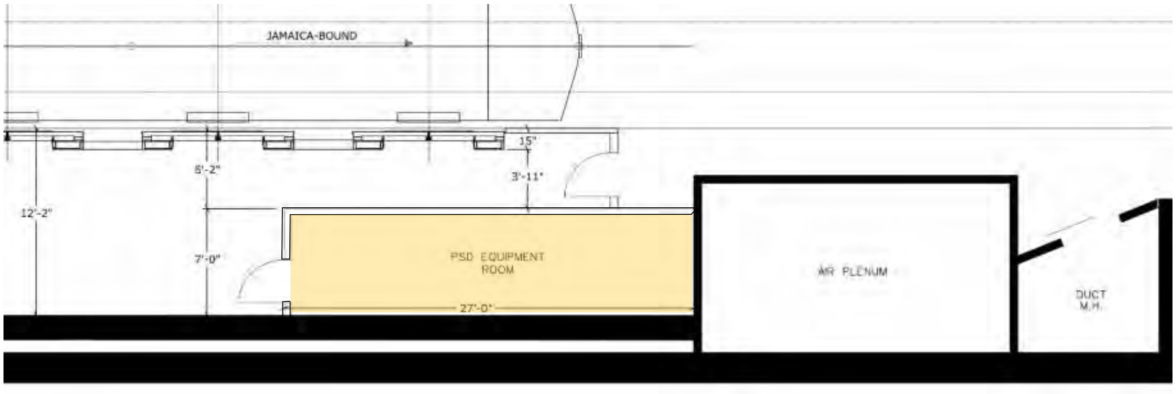

Figure 2 – PSD Equipment Room Detail – Roosevelt Island Station

half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

The 2012 NYCT conditions survey gave the platform edges an average rating of 3.25. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: Linear fluorescent lighting is surrounded by a continuous 1'-6" tube fixture. The fixtures are 20" from the edge of the platform and have a vertical clearance of 7'-10". As the ceiling heights vary, the lighting is either suspended with angular supports some of which extend over the platform edge (figure 3) or mounted on the ceiling (figure 4). There is also cove lighting along the top of the back wall of the platforms.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station. MRN 222 has adequate capacity to support the implementation of a APG/PSD system.

Station
Power Capacity Analysis

NYCT Station MR Number	222
Station Name	Roosevelt Island
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	555.8
Apparent Power (kVA)	694.8
Station Peak Demand Load, Max Current, (A)	1930.0
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	2125
Station Service Power Capacity, (Main SB or SG Rating), (A)	5500
Service Spare Capacity, (A)	3375
Is Electrical Service Adequate?	Yes
Notes	Station has 2500 A service @ 460 Volt (not 208 V) with max demand of 555.8 KW. We have converted ratings values to 208 V. Station does not have 1 line diagram.

Table 1. MRN 222 Power Capacity Analysis

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.5M to install APGs and $40.8M to install PSDs (See Appendix E)

Figure 3 – Typical platform view featuring curved walls and ceilings- Roosevelt Island Station

Figure 4 – Platform view featuring low planar ceiling with cured and straight walls- Roosevelt Island Station

1.10 MR-223 | Lexington Avenue-63rd Street Station

Summary: *Lexington Avenue-63rd Street Station (MR-223) is feasible for both APGs and PSDs. The recent renovation work at this station conceals the structure at the platform edge. Modifications to this renovation work may be needed to accommodate a PSD system. Structural work would only be required in the implementation of APGs (see structural report; Appendix B). It is assumed that power is adequate.*

Description

Lexington Avenue- 63rd Street Station is a below-grade station with two straight center/island platforms (see figure 1). The platforms are stacked; the upper level provides Coney Island-bound service, while the lower level provides Jamaica-bound service. These platforms also provides Q-line service, similarly with the directions of travel on separate platform levels. This station was renovated in the Second Avenue Subway expansion (opened January 2017). Four elevators are located in a vestibule at the east-end of the station. The platform structure is cast-in-place concrete. Back-of-house elements are located at the end of the platforms and at the mezzanine levels. At the middle of both platforms there are six columns in two rows spaced 8'-0" apart with column faces 4'-6" from the edge of the platform. In addition to these columns, the lower level has a row of columns centered on the platform width spaced 15'-0" on center. At the upper level, there are ceiling mounted metal panels that are angled and extend beyond the platform edge (see figure 3). At the lower level, there are horizontal metal mesh panels covering the beams at and beyond the platform edge (see figure 4).

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Due to the treatment of the ceilings at and beyond the platform edge, modification of metal panels may be necessary to create the supporting structure of a full height system.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

This station will need two equipment rooms as there are four platform edges. For the two F-line platform edges, one room can be located in the middle of the lower level platform between the existing columns. The proposed room dimension is 12'-0" x 16'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'F' Line Stations
(Lexington Avenue-63rd Street Station)

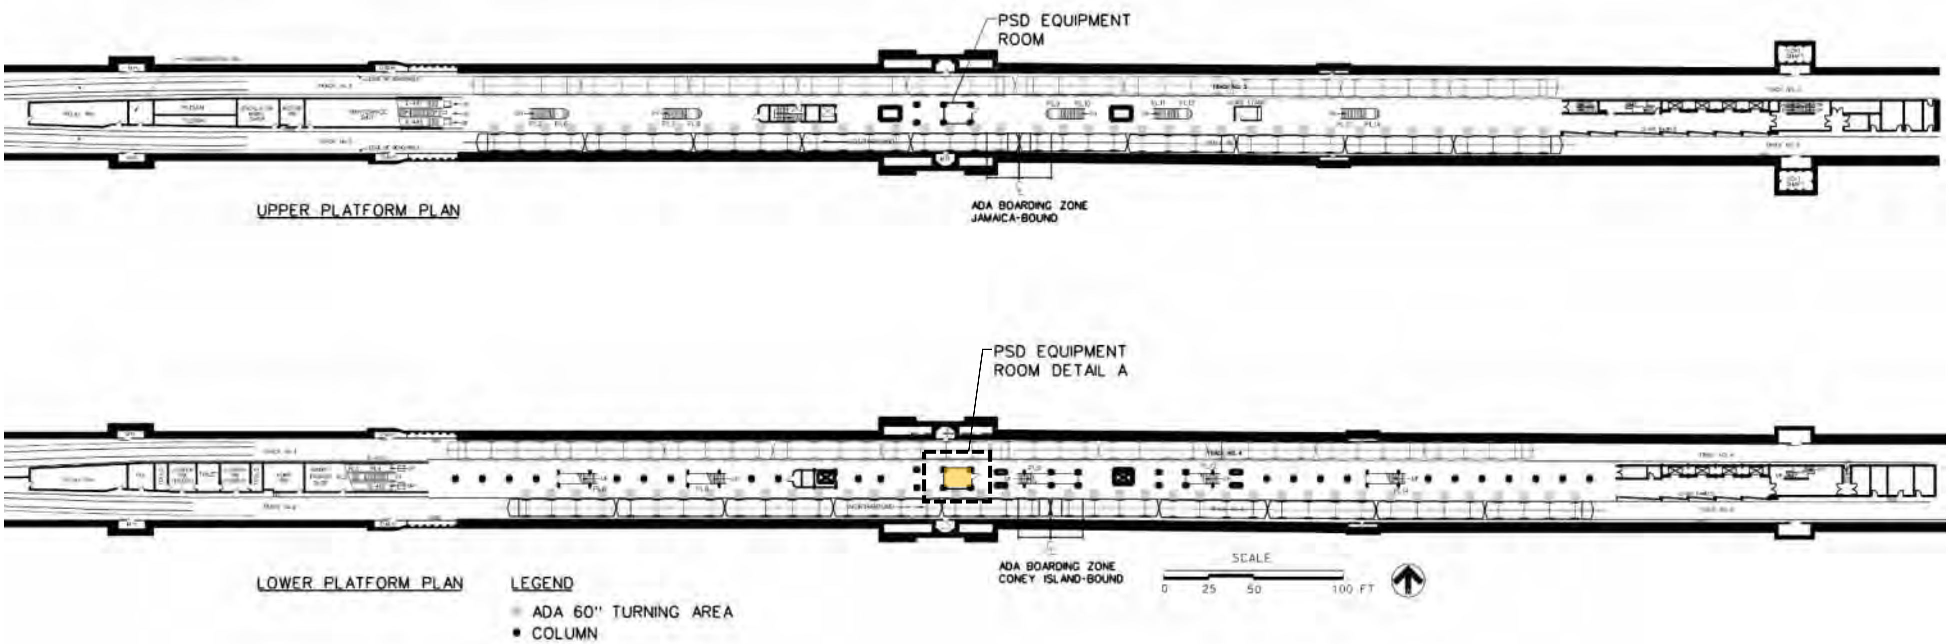

Figure 1 – Station Plan- Lexington Ave.-63rd St. Station

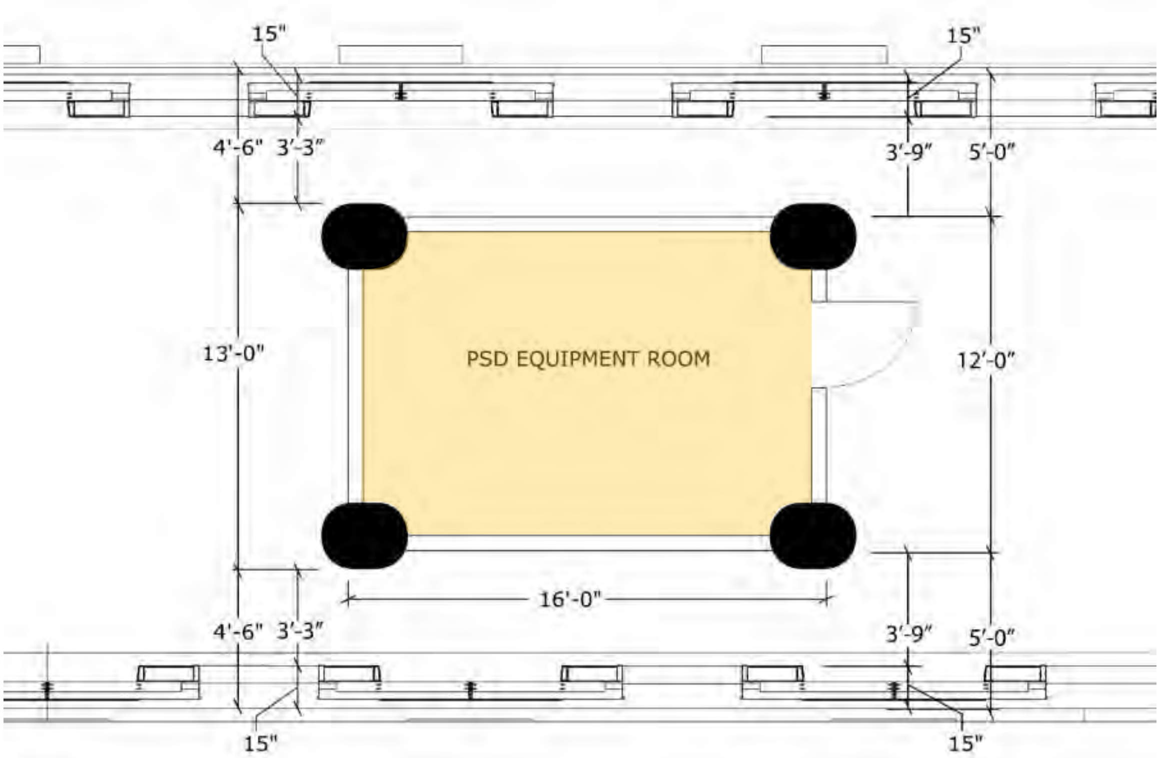

Figure 2 – PSD Equipment Room Detail – Lexington Ave.-63rd St. Station

Platform Edge Condition

The platform edge consists of a cast-in-place concrete cantilever that is approximately 1'-2" long and is approximately 5" thick. The platform also includes a 3" allowance for a floor finish, which was conservatively assumed to be a concrete topping slab for the purpose of assessing dead loads. The cantilever portion is reinforced with #4 rebar at 12" O.C. at the top of the slab. The station was designed in 1975, therefore it was assumed that the reinforcing rods have a yield strength of 40,000 psi (Grade 40) in the absence of additional information (Grade 60 rebar was in existence at the time, but not standard as it is today). The concrete has a compressive strength of 3000 psi, per the notes on the record drawings.

Based upon the record drawings and the above assumptions, it was found that the cantilever edge has sufficient capacity to support a full height PSD system in its current condition. It cannot, however, support half height cantilevered APGs without rebuilding the platform edge to achieve a higher strength. This difference is due to the fact the APG system is fully supported at the cantilever edge and results in transfer of moment to the slab edge caused by crowd thrust and wind loading (piston effect), in addition to the weight of the system itself. The PSD system results in a moment on the slab edge due to its weight only. In both cases, self-weight of the slab edge and live load on the platform have been accounted for. The wind load and crowd thrust also result in direct tension on the slab edge, for which the slab has sufficient capacity in either case.

As this station was recently renovated, the platform edge score from the 2012 NYCT conditions survey is not a reflection of current conditions.

Platform obstructions within 5' of edge:

Coney Island-bound: There are three columns that are 4'-7" away from the platform edge.

Jamaica-bound: There are three columns that are 4'-7" away from the platform edge.

Lighting:

Existing lighting: Lighting comprises of 1'-6" fluorescent tubes recessed above removable ceiling panels, and encased fluorescent tubes installed approximately 60" away from the platform edge

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.6M to install APGs and $39.3M to install PSDs (See Appendix E)

Figure 3 – Platform edge condition on the lower level (Coney Island-bound)- Lexington Ave.-63rd St. Station

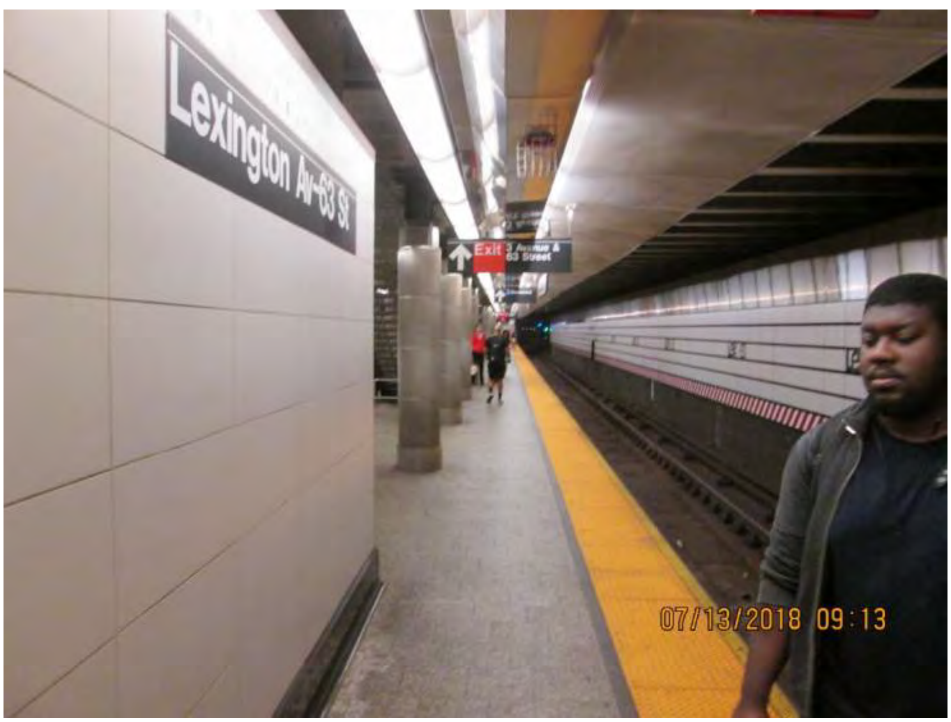

Figure 4 –Platform edge condition on the lower level (Jamaica-bound)- Lexington Ave.-63rd St. Station

1.11 MR-224 | 57th Street Station

***Summary:** 57th Street Station (MR-224) is not feasible for both APGs and PSDs. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform. At some stairs, the 32" minimum requirement for wheel chair circulation would not be met on one side of the platform. See figure 1 for the typical non-compliant condition occurring on one side of the platform.*

Description

57th Street Station is a below-grade station consisting of one straight center/island platform. The cast-in-place concrete platforms are accessed via a mezzanine. There are six stairs on the platform. Four of these stairs are shifted towards one side of the platform adjacent to columns. The platform is approximately 23'-0" wide. Column spacing along the length of the platform is approximately 15' on center and column faces are typically 3'-4" to the edge of the platform. Currently, at all stairs along the length of the platform, a wheel chair can move between the columns and the platform edge (3'-4"). Four of the six stairs are off center as shown in figure 1. Although there is adequate clear space on one side of the platform, the implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement at the other side. Both platform edges need to comply in order for the station to be deemed feasible for the implementation of a platform edge barrier.

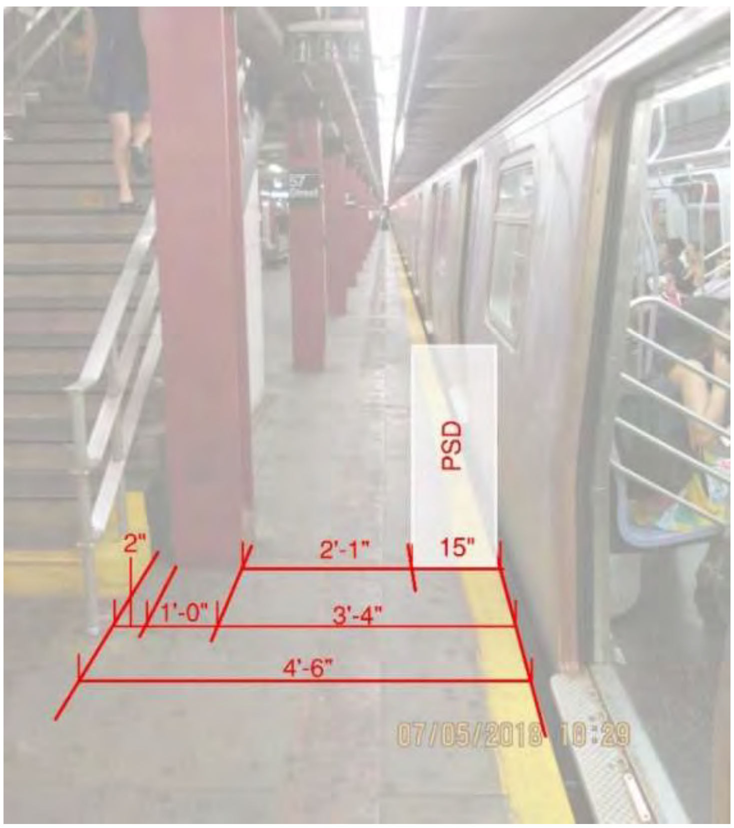

Figure 1 – Non-compliant ADA condition on one side of the center/island platform- 57th Street

Table of Contents

1.12 MR-232 | 2nd Avenue Station

Summary: *2nd Avenue (MR-232) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. There a flue vents located at the center of both platforms, flanked by columns on both sides of the platform. The ADA constraints occur due to columns surrounding the vent flues on both center/island platforms. Currently, the distance between the column and the edge of the platform is 36" and the spacing between the column and the wall of the vent flue is 18" on one side and 30" on the other. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at vent flues as the remaining width would be 21" (see figure 1).*

Description

2nd Avenue Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 19'-4". A vent is centered on both the Jamaica-bound and Coney Island-bound platforms. Currently, there is an ADA compliant path of travel between the column face and the platform edge (3'-0"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 21" would not allow for ADA compliant wheelchair movement.

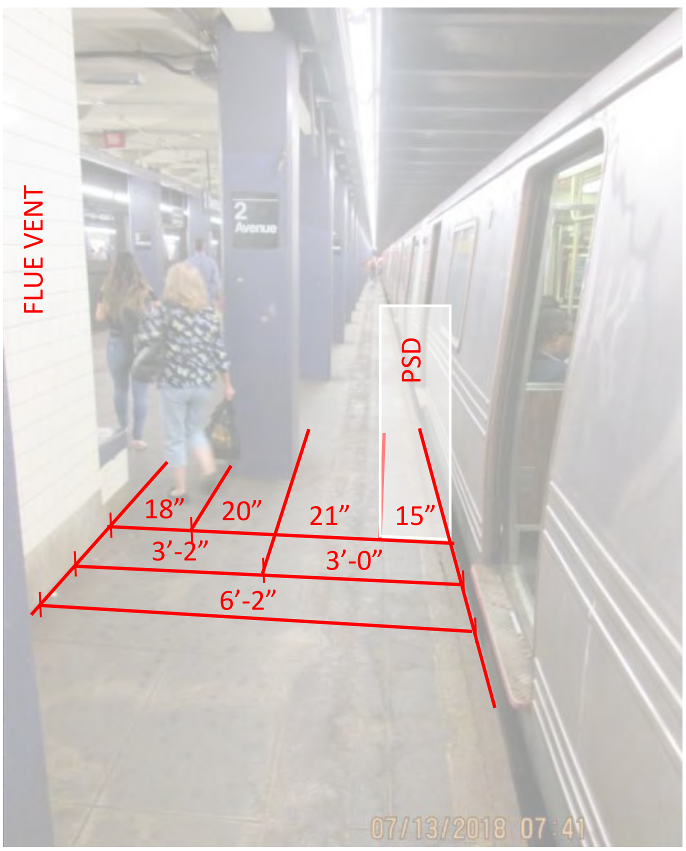

Figure 1 – Non-compliant ADA condition at flue vent- 2nd Avenue Statio

1.13 MR-233 | Delancey Street Station

Summary: *Delancey Street Station (MR-233) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, there are two locations along the Jamaica-bound platform that would result in non-compliant conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met due to the location of an existing escalator and an escalator pit room. In the implementation of a platform edge barrier, the widest remaining widths in either situation would be 30" and 26" respectively (see figures 1 and 2).*

Description

Delancey Street Station is a below-grade station with straight side platforms. The platform structure is cast-in-place concrete. The width of both side platforms is approximately 12'-8". Columns are spaced 15'-0" on center with faces 3'-0" from the platform edge. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-0"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32" at two specific locations on the Jamaica-bound platform (see figures 1 and 2). Remaining widths would not allow for ADA compliant wheelchair movement.

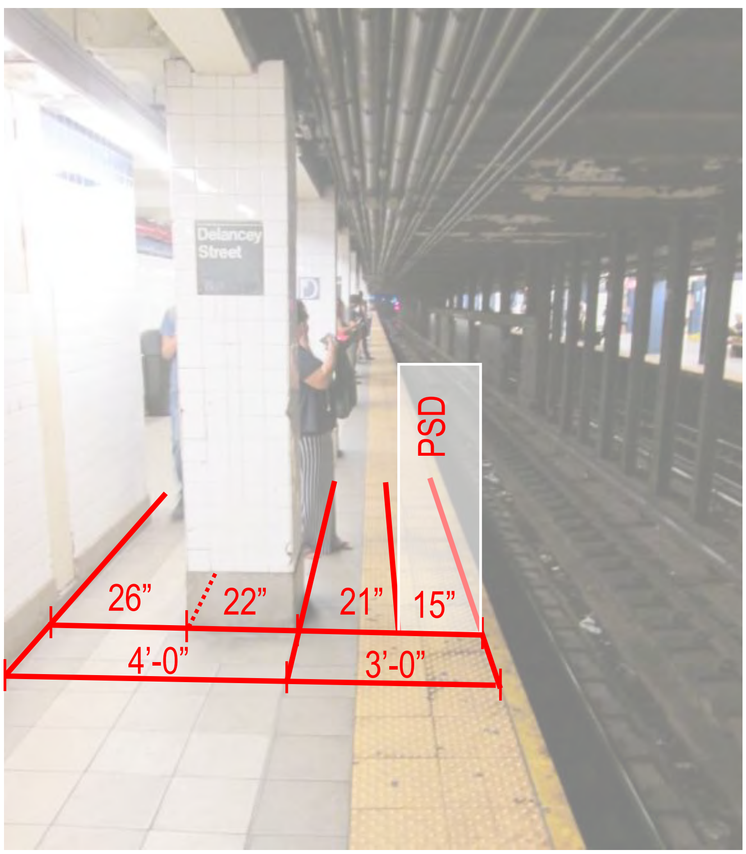

Figure 1 – Non-compliant ADA condition at escalator 328- Delancey Street Station

1.14 MR-234 | East Broadway Station

***Summary:** East Broadway Station (MR-234) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met at five of the seven stairs/escalators. The remaining width would be 25" (see figure 1). The stairs/escalators at this station are typically off-center, located closer to the local track platform edge. Currently, columns divide the 6'-0" width between the platform edge and the stairs/escalators.*

Description

East Broadway Station is a below grade station with a straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 17'-6". Columns are spaced 15'-0" on center with column faces 3'-4" from the platform edge. Passengers requiring an ADA compliant path can currently move in the 3'-4" space between the stairs and platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" would not allow for ADA compliant wheelchair movement.

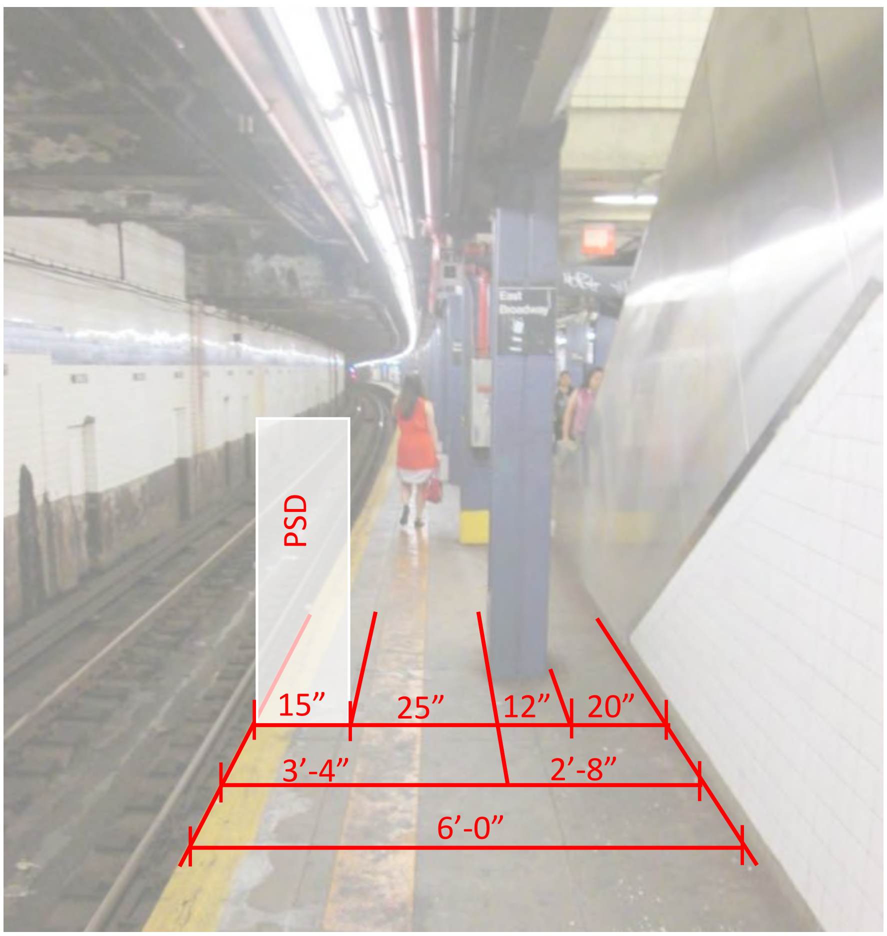

Figure 1 – Non-compliant ADA condition at stairs/escalator (typical)- East Broadway Station

1.15 MR-235 | York Street Station

Summary: *York Street Station (MR-235) is feasible for both APGs and PSDs. There is area at the south-end of the platform where a PSD equipment room can be located. Platform structural work will be required to support the requirements of an APG or PSD system (see structural report; Appendix B). It is assumed that existing power is adequate.*

Description

York Street Station is a below-grade station with a straight center/island platform (see figure 1). The platform has one stair at the north-end of the platform. The platform structure is cast-in-place concrete. Back-of-house elements are situated in the mezzanine, which is connected to the station platform through a ramp passageway. The platform width is approximately 18'-8" wide. There are two rows of columns that are spaced 15'-0" on center, with column faces 2'-8" from the platform edge. The distance between the two rows of columns is typically 11'-0". For an overall station plan, see figure 1. See figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted and hung conduits below the platform edge would need to be relocated to accommodate the requirements of the APG system.

Equipment Room

One room can be accommodated at the south-end of the platform. The proposed room dimension is 12'-0" x 16'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Structural work should be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair

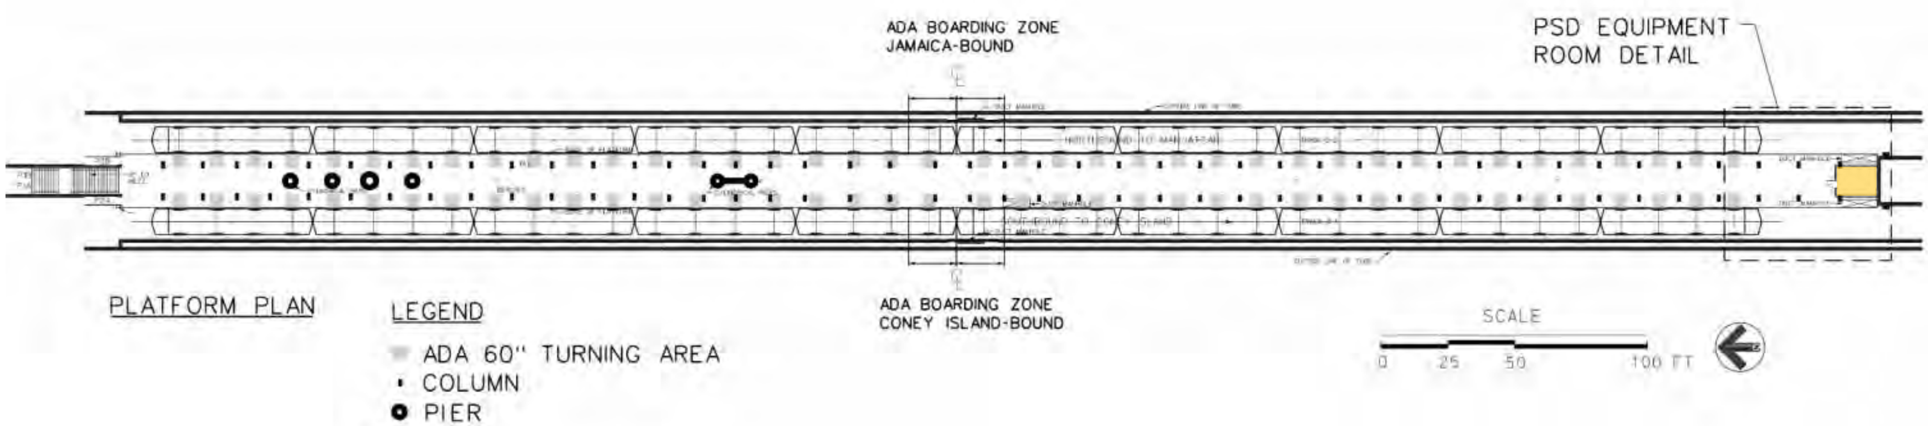

Figure 1 – Station Plan-York Street Station

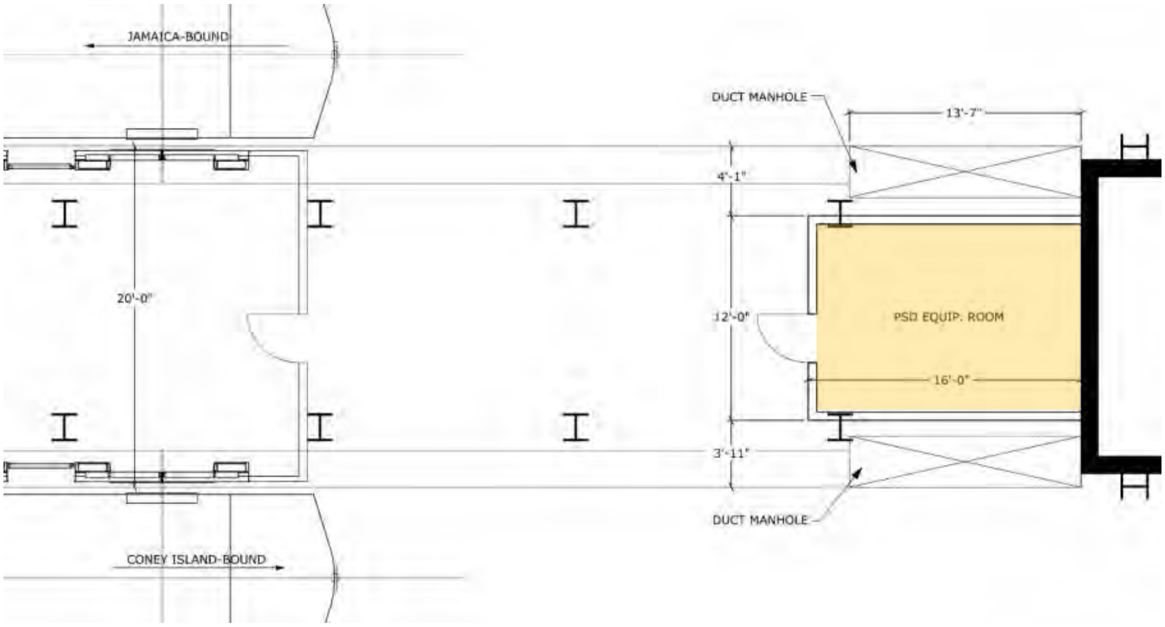

Figure 2 – PSD Equipment Room Detail – York Street Station

Platform obstructions within 5' of edge:

All columns are 32" from the platform edge. Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A.

Lighting:

Existing lighting: Linear fluorescent; approximately 1' from the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.5M to install APGs and $41.2M to install PSDs (See Appendix E).

Figure 3– Typical platform view- York Street Stati

Table of Contents

1.16 MR-174 | Jay Street-MetroTech Station

Summary: *Jay Street-MetroTech Station (MR-174) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. The platforms serving the 'F' line also serve the 'A' and 'C' lines. In the implementation of a platform edge barrier, the 32" minimum pinch width requirement for ADA compliant wheelchair movement would not be met at several stairs on both platforms. These stairs are not centered on the width of the platform, but are closer to the 'A' and 'C' track side of the platform. In these conditions, the remaining width would be 27" (see figure 1). Although the minimum required circulation width is met on one side of the platform, compliance is required on both sides of the platform in order to be feasible.*

Description

Jay Street-MetroTech Station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete and serves the 'F', 'A', and 'C' lines. The width of the platform is approximately 24'-8". Columns are spaced 15'-0" on center with column faces 3'-6" away from the platform edge. The columns on the northbound (Jamaica-179th Street) platform are exposed, while on the southbound (Coney Island-Stillwell Avenue) platform have a tile surround. On both platforms, column faces are 3'-6" from the platform edge. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-6"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 27" would not allow for ADA compliant wheelchair movement.

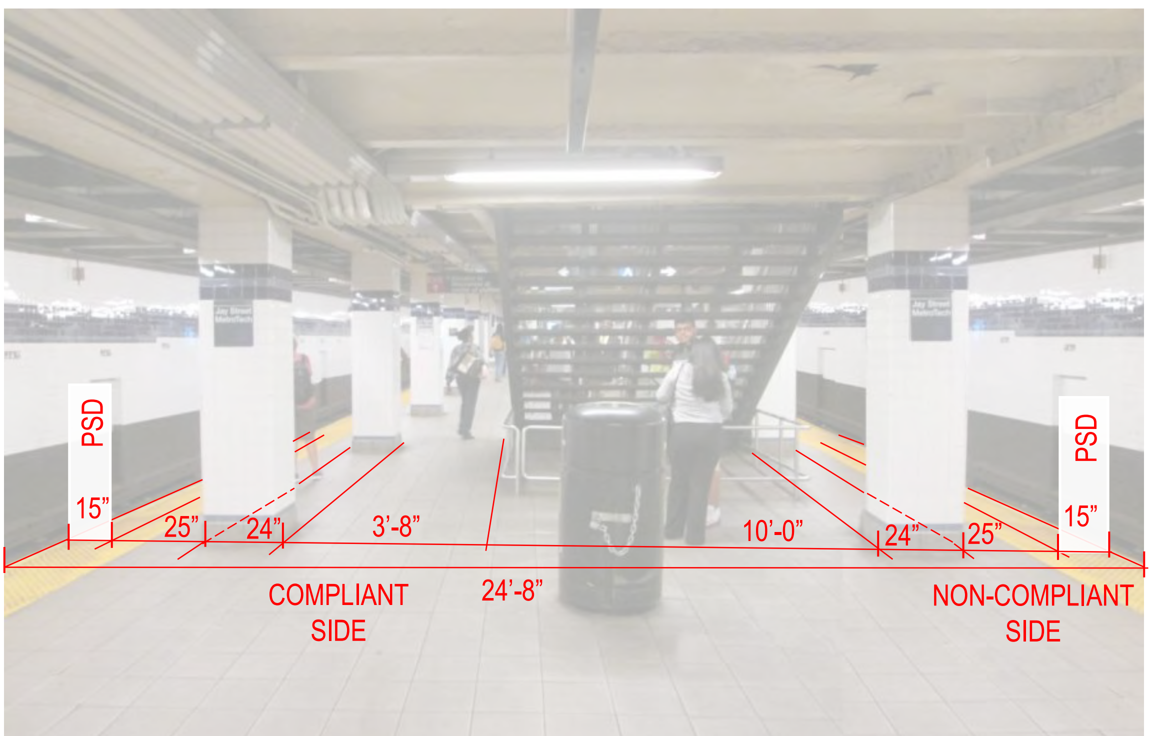

Figure 1 – Non-compliant ADA condition on one side of platform (southbound)- Jay Street- MetroTech Station

1.17 MR-244 | Ditmas Avenue Station

Summary: *Ditmas Avenue Station (MR-244) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

Ditmas Avenue Station is an elevated station consisting of two side platforms. Both platforms are 11'-4" wide. The platform is straight with a row of a columns against the back wall of the platform. The canopy covers the entirety of the platform length. See figure 1 for a general platform view of Ditmas Avenue Station. The stair at the north-end of the platform is 3'-6" away from the platform edge. In the implementation of a platform edge barrier, the remaining width at the stair would be insufficient for wheelchair movement.

Figure 1– Non-compliant ADA Condition – Ditmas Avenue Station

Figure 2– Precast T-Beam platform – Ditmas Avenue Station

Table of Contents

1.18 MR-245 | 18th Avenue Station

Summary: *18th Avenue Station (MR-245) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

18th Avenue Station is an elevated station consisting of two center/island platforms, one of which is currently not in service. The accessible platform is 16'-4" wide. The platform is straight with a row of columns centered on the width of the platform. The canopy covers the entirety of the platform length. The stair at the north-end of the platform is 3'-6" away from the platform edge. In the implementation of a platform edge barrier, the remaining width at the stair would be insufficient for wheelchair movement.

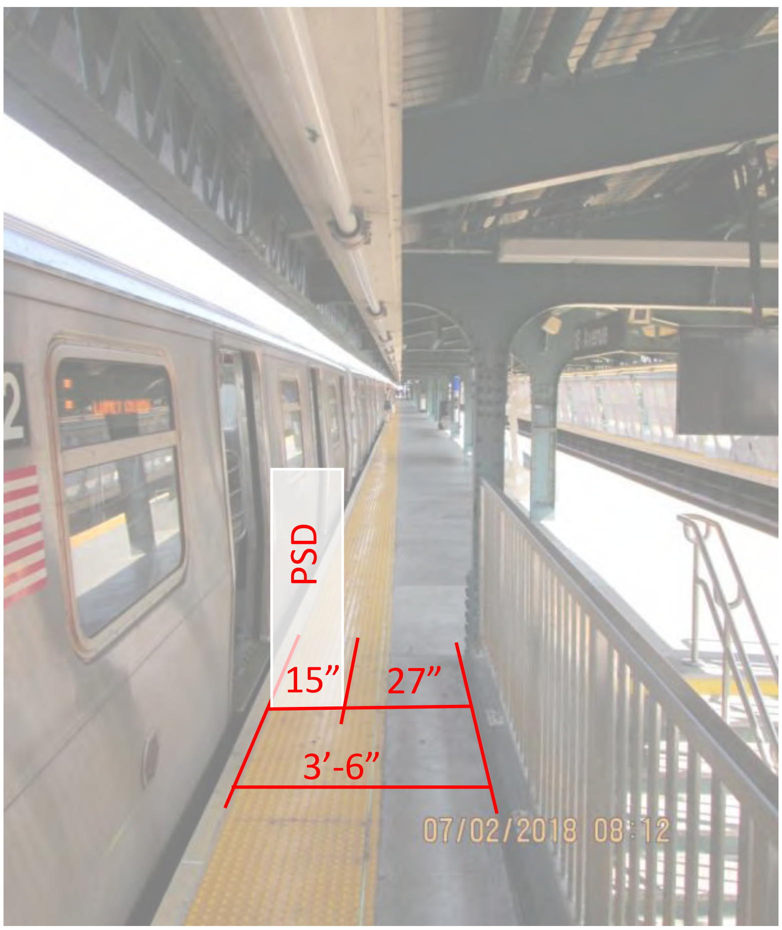

Figure 1– Non-compliant ADA condition – 18th Avenue Station

Figure 2– Precast T-Beam platform – 18th Avenue Station

1.19 MR-246 | Avenue I Station

Summary: *Avenue I Station (MR-246) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the south-end of both platforms, the 32" required width would not be met as the remaining width would be 17" (see figure 1).*

Description:

Avenue I Station is an elevated station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns against the back wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The stair at the south-end of the platform is 32" away from the platform edge. In the implementation of a platform edge barrier, the remaining width adjacent to the stair would be insufficient for wheelchair movement.

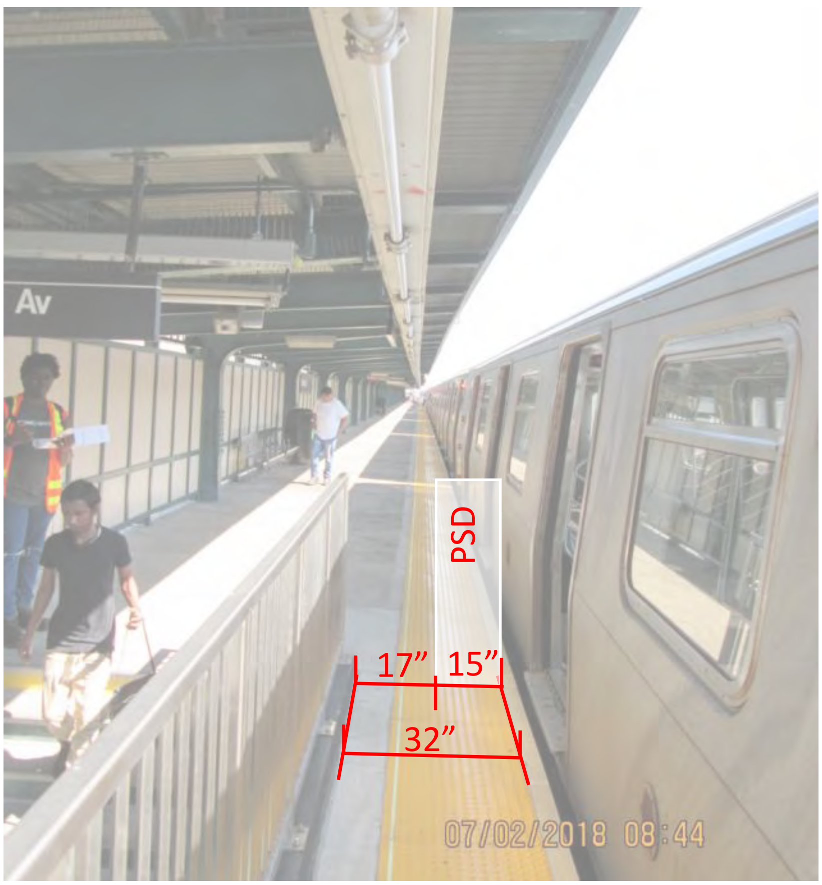

Figure 1– General Platform Condition – Avenue I Station

Figure 2– Precast T-Beam platform – Avenue I Station

1.20 MR-247 | Bay Parkway Station

Summary: *Bay Parkway Station (MR-247) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description:

Bay Parkway Station is an elevated station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns flush with the wall of the platform, which supports the station canopy. The canopy covers approximately half of the platform, which is found to be inadequate cover for a full height PSD system. See figure 1 for a general platform view of Bay Parkway Station.

Figure 1– General Platform Condition – Bay Parkway Station

Figure 2– Precast T-Beam platform – Bay Parkway Station

1.21 MR-248 | Avenue N Station

Summary: *Avenue N Station (MR-248) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. At the stairs on the north-end of both platforms, the 32" required width would not be met (see figure 1).*

Description:

Avenue N Station is an at-grade station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns flush with the wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The stair at the south-end of the platform is 28" away from the platform edge. This width is currently not ADA compliant and the implementation of a platform edge barrier would further exacerbate this condition.

Figure 1– General Platform Condition – Avenue N Station

Figure 2– Precast T-Beam platform – Avenue N Station

1.22 MR-249 | Avenue P Station

Summary: *Avenue P Station (MR-249) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). Additionally, the implementation of a platform edge barrier would result in non-compliant ADA conditions. The stairs are located at the center of the platform and are 3'-8" (44") away from the platform edge. In the implementation of a platform edge barrier, the 32" required width would not be met as the remaining width would be approximately 29" (see figure 1).*

Description:

Avenue P Station is an at-grade station consisting of two side platforms, one of which is currently not in service. Each platform is 11'-4" wide. The platform is straight with a row of a columns against the wall of the platform, which supports the station canopy. The canopy covers the entirety of the platform length. The centrally located stairs are 3'-8" (44") away from the platform edge. The implementation of a platform edge barrier would not allow for ADA compliant wheelchair movement.

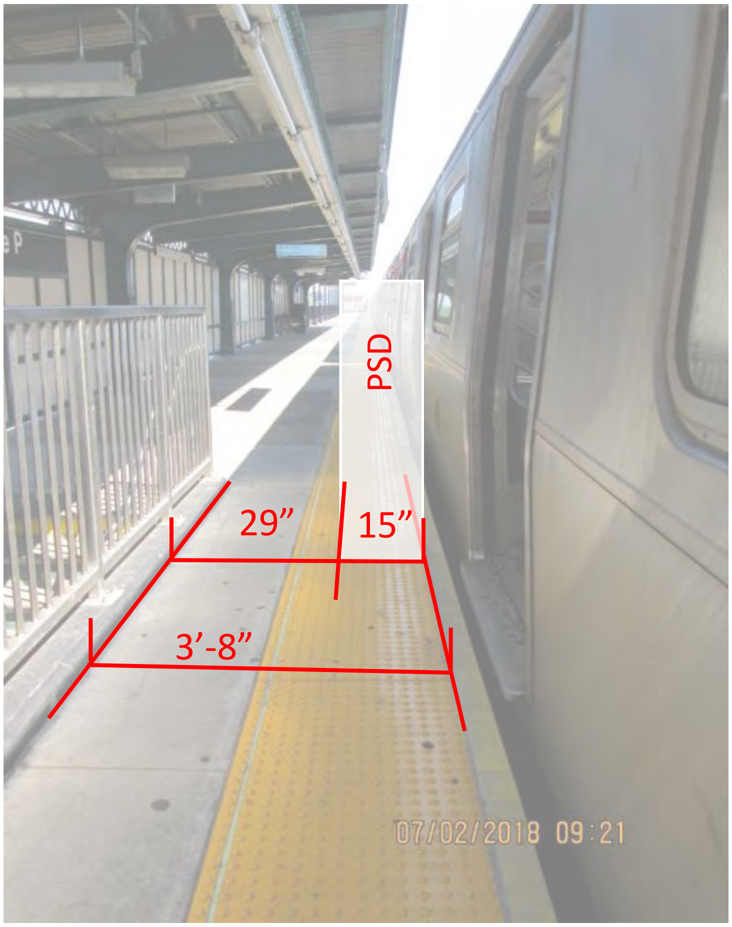

Figure 1– Non-compliant ADA condition at stairs – Avenue P Station

Figure 2– Precast T-Beam platform – Avenue P Station

1.23 Mr-250 | Kings Highway Station

Summary: *Kings Highway Station (MR-250) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description:

Kings Highway Station is an at-grade station consisting of two center/island platforms, one of which is currently not in service. Each center platform is 16'-4" wide. The platform has a singular row of columns supporting a canopy with a spacing of 7'-8" from the column to the edge of the platform. The canopy covers the entirety of the platform length. See figure 1 for a general platform view of Kings Highway Station.

Figure 1– General Platform Condition – Kings Highway Station

Figure 2– Precast T-Beam platform – Kings Highway Station

1.24 MR-251 | Avenue U Station

Summary: *Avenue U Station (MR-251) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, the stair on the south-end of both platforms is located 2'-8" (32") from the platform edge. In the implementation of a platform edge barrier, the remaining width would not allow for ADA-compliant wheelchair movement (see figure 1).*

Description:

Avenue U Station is an elevated station consisting of two center platforms, one of which is currently not in service. Each center platform is 11'-4" wide. The platform is straight with a row of a columns against the wall of the platform. The canopy covers the entirety of the platform length. The stairs at the south-end of both platforms is close to the platform edge and would not allow for ADA-compliant wheelchair movement with a platform edge barrier installed.

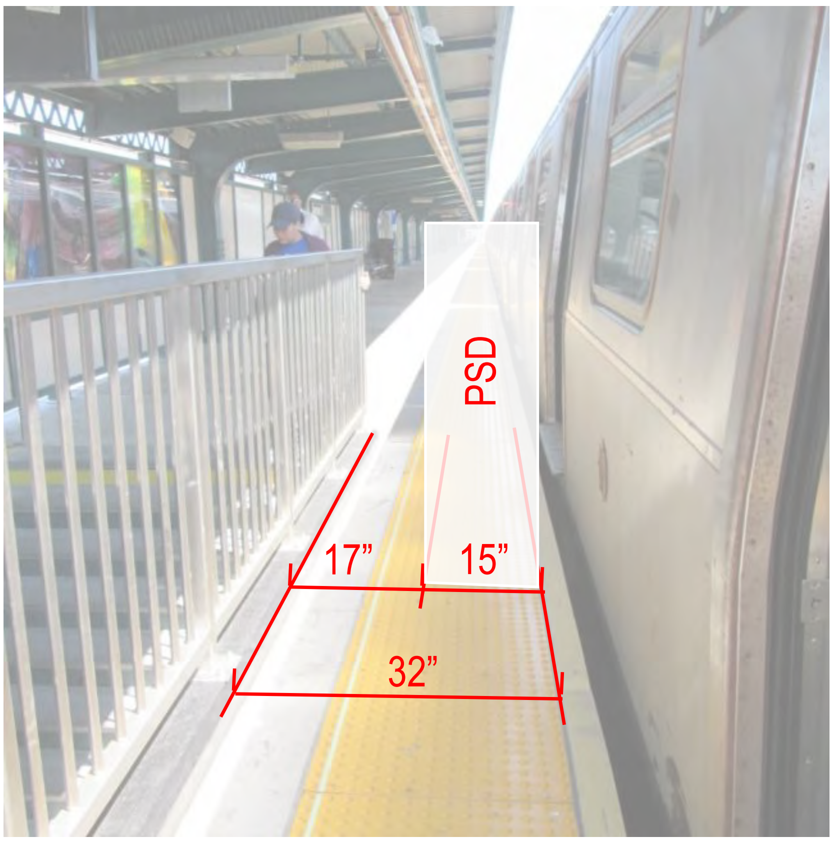

Figure 1– Non-compliant ADA condition at stairs– Avenue U Station

Figure 2– Precast T-Beam platform – Avenue U Station

1.25 MR-252 | Avenue X Station

__Summary:__ Avenue X Station (MR-252) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, the stair on the north-end of the Jamaica-bound platform is located 3'-8" (44") from the platform edge. In the implementation of a platform edge barrier, the required 32" width for wheelchair movement would not be met as the remaining width would be 29" (see figure 1).

Description:

Avenue X Station is an elevated station consisting of two side platforms. Each side platform is approximately 10'-0" wide. The platform is slightly curved with a row of a columns against the back wall of the platform. The canopy covers the entirety of the platform length. The stair at the north-end of the Jamaica-bound platform is close to the platform edge. In this location, the required 32" width for ADA compliant wheelchair movement would not be met with a platform edge barrier installed.

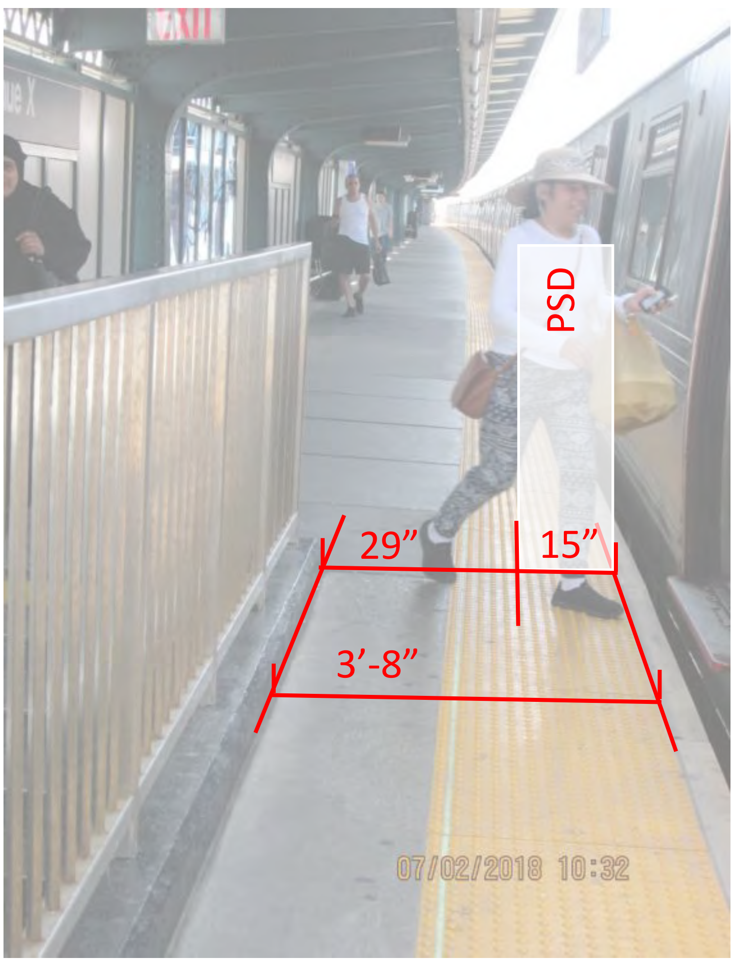

Figure 1– Non-compliant ADA condition – Avenue X Station

Figure 2– Precast T-Beam platform – Avenue X Station

1.26 MR-253 | Neptune Avenue Station

Summary: *Neptune Avenue Station (MR-253) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2). In addition, at the centrally located stairs are 3'-10" (46") away from the platform edge. In the implementation of a platform edge barrier, the required 32" width for wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description:

Neptune Avenue Station is an elevated station consisting of a straight center/island platform. The platform is approximately 15'-2" wide. Columns are centered on the width of the platform. Full height PSDs would not be feasible as there is limited canopy cover. The centrally located stairs are close to the platform edge. Adjacent to the stairs, the required 32" width for ADA compliant wheelchair movement would not be met with a platform edge barrier installed.

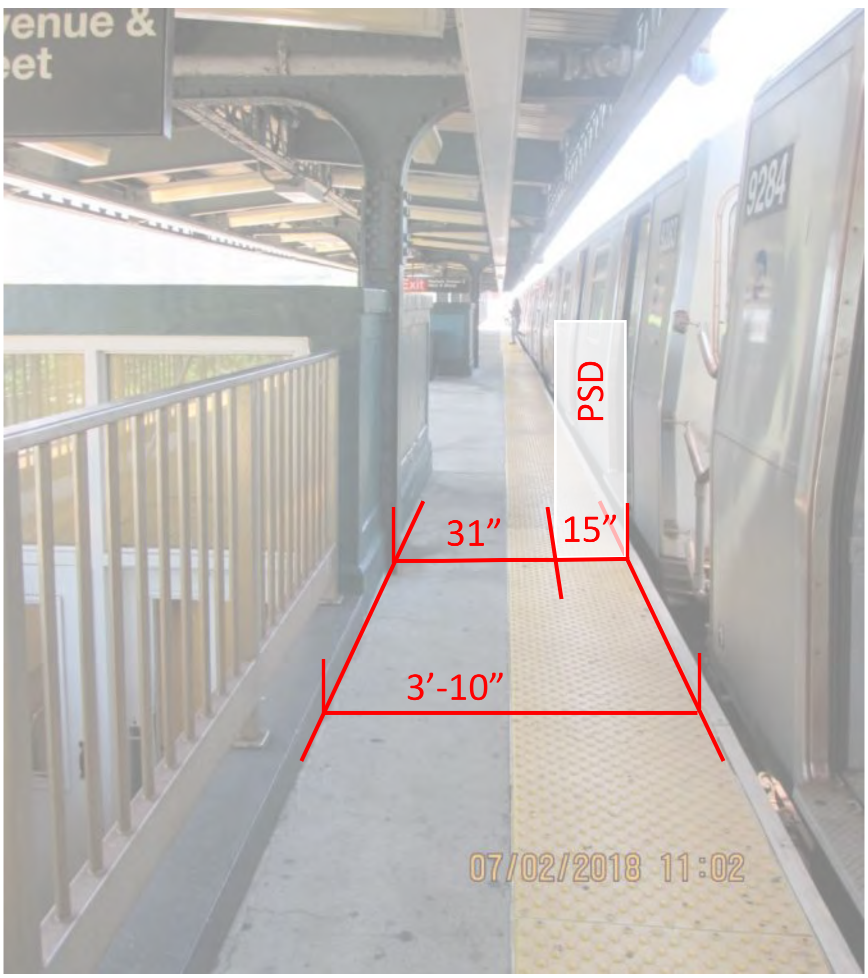

Figure 1– General Platform Condition – Neptune Avenue Station

Figure 2– Precast T-beam Platform – Neptune Avenue Station

1.27 MR-57 | West 8th Street- NY Aquarium Station

Summary: *West 8th Street- NY Aquarium Station (MR-57) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. This issue would occur due to the elevator/escalator room located on the Jamaica-bound platform. A column divides the width between the existing room and the platform edge. This column currently does not allow for wheelchair movement on the Jamaica-bound platform. The 32" minimum requirement for ADA compliant wheelchair movement is currently not met and would be exacerbated in the implementation of a platform edge barrier (see figure 1).*

Description

West 8th Street- NY Aquarium Station is an elevated station with slightly curved side platforms that serve the 'F' and 'Q' trains. The lower platform level serves the 'F' line and the upper platform serves the 'Q' line. The platform structure is cast-in-place concrete. The width of the platform varies from 12'-10" to 5'-2". Columns are typically 2'-3" from the platform edge. Currently, the station does not have an ADA compliant path of travel along the Jamaica-bound platform. The elevator/escalator room is 5'-2" from the platform edge a column segments this width into a 1'-4" and a 2'-4" path of travel. The implementation of a platform edge barrier would further constrain this non-compliant condition.

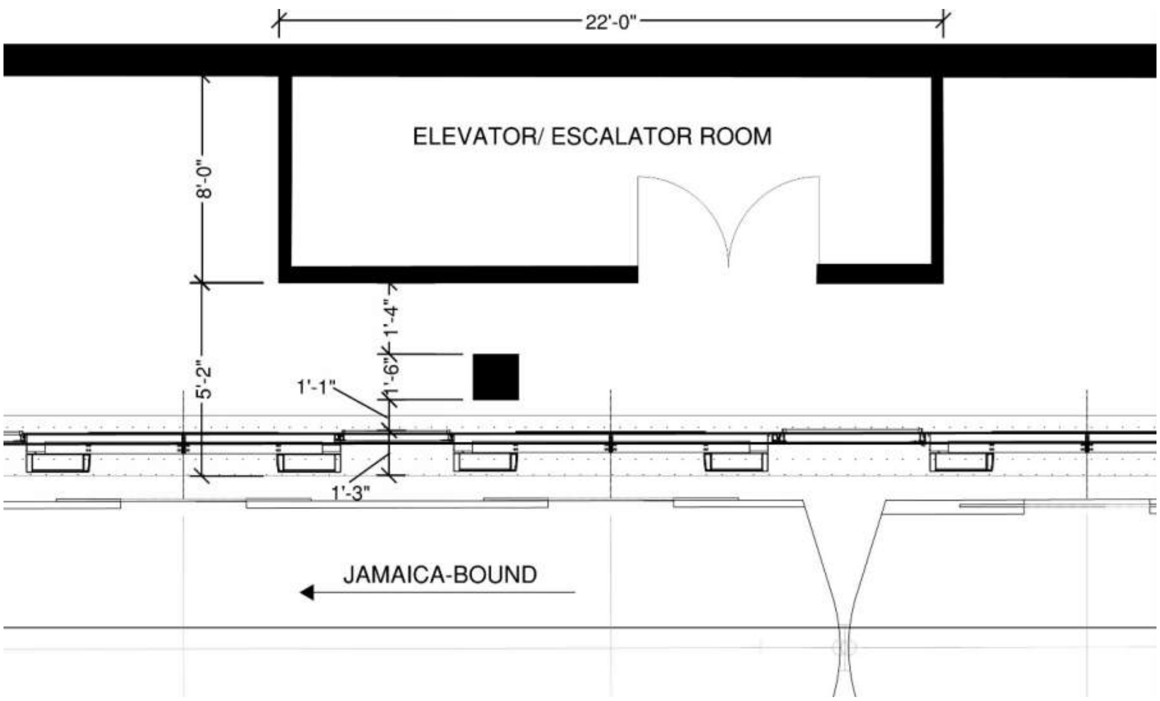

Figure 1 – Non-compliant ADA condition on the Jamaica-bound platform- West 8th St-NY Aquarium

1.28 MR-58 | Coney Island-Stillwell Avenue Station

Summary: *Coney Island-Stillwell Avenue Station (MR-58) is feasible for both APGs and PSDs. This station is the terminus station for the 'N', 'Q', 'D', and 'F' trains. Tracks 5 and 6 serve the F line from a shared center/island platform. The canopy at this station is very tall, and there are no structural members directly above the platform edge. For the installation of a full height PSD system, structural members would have to be attached to existing beams that are approximately 12'-0" high and 5'-0" from the platform edge. One and a half train cars are not covered by a canopy, supplemental overhead structure would be needed in this small along the platform. Platform structural work will be required to support the requirements of an APG and PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Coney Island-Stillwell Avenue Station is an elevated station with four center/island platforms (see figure 1). Each train that is served at this station has a center/island platform for its use only. The 'F' line platform is mostly straight, but tapers at the north-end of the platform. The platform structure is made of cast-in-place concrete. There are two stairs and a centrally located ramp that provide access to the mezzanine level below. Back-of-house elements are situated on the platform ends and in the mezzanine. There are two rows of columns along the length of the platform. These columns are spaced approximately 20'-0" on center with column faces 6'-10" from the platform edge. The platform varies from 20'-0" to 26'-0" wide. One and a half train cars are not covered by the canopy, a supplementary overhead structure would be required in these locations to accommodate a platform edge barrier. See figure 1 for an overall station plan.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As indicated in the summary, there is not structure to mount to directly above the platform edge, some additional framing would be needed in this station (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated on the platform between columns at the center of the platform. The proposed room would measure approximately 16'-0" x 7'-6" (see figure 2). The other lines that are served at this station could use a similar room location on their respective platform (see figure 1)

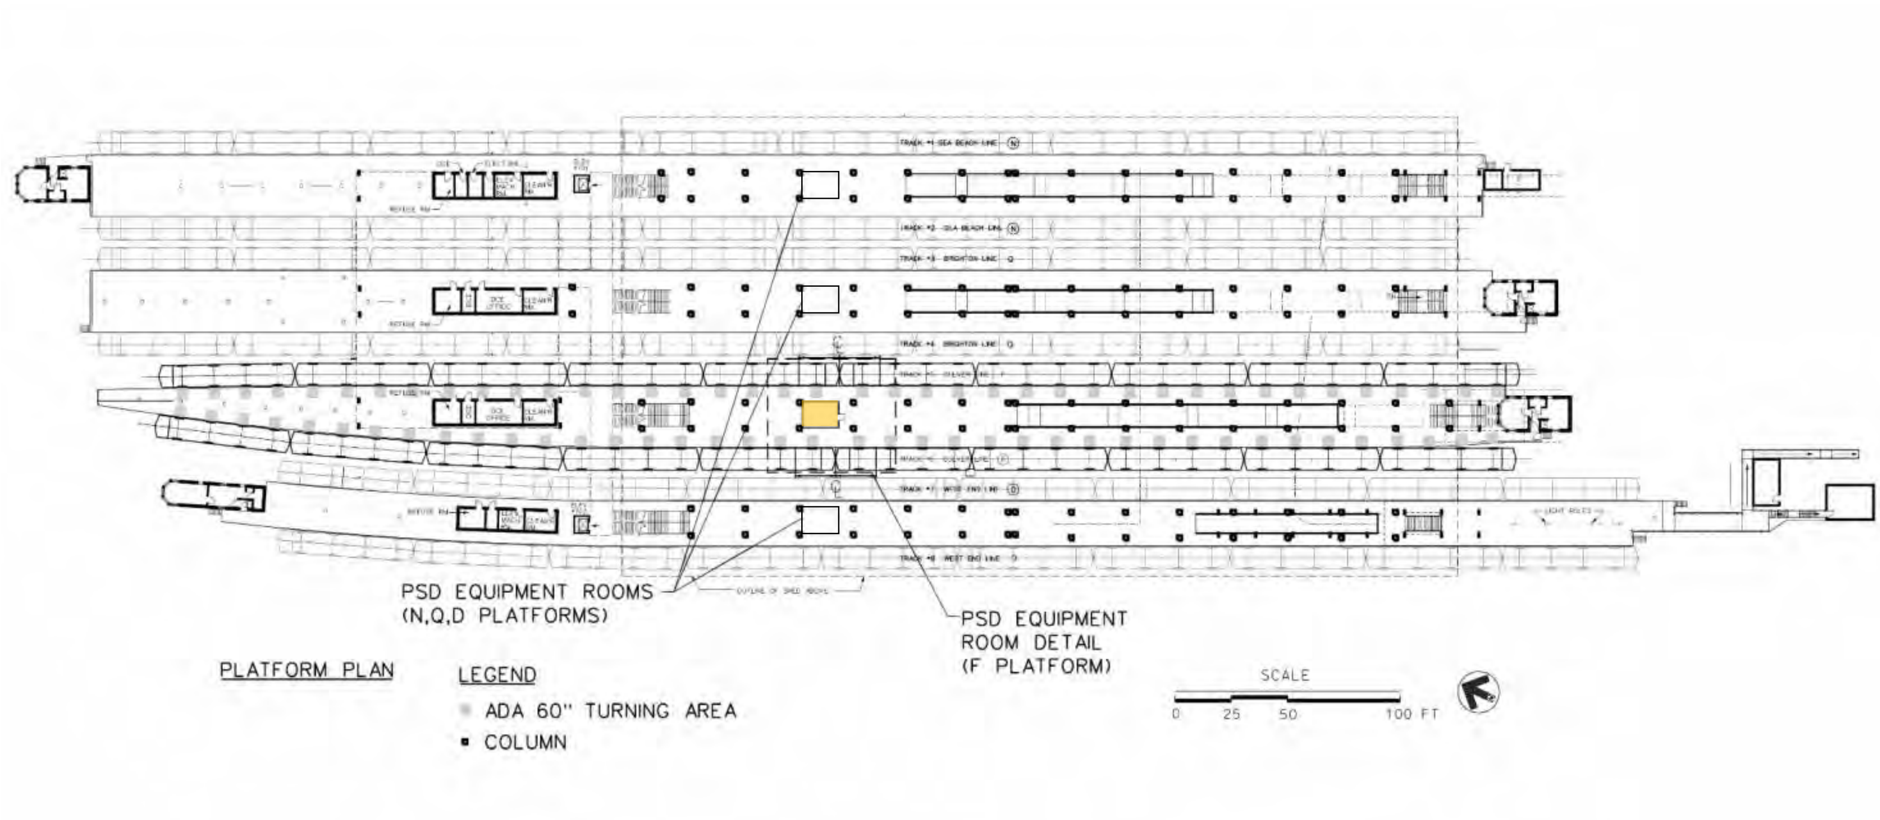

Figure 1 – Station Plan- Coney Island-Stillwell Avenue Station

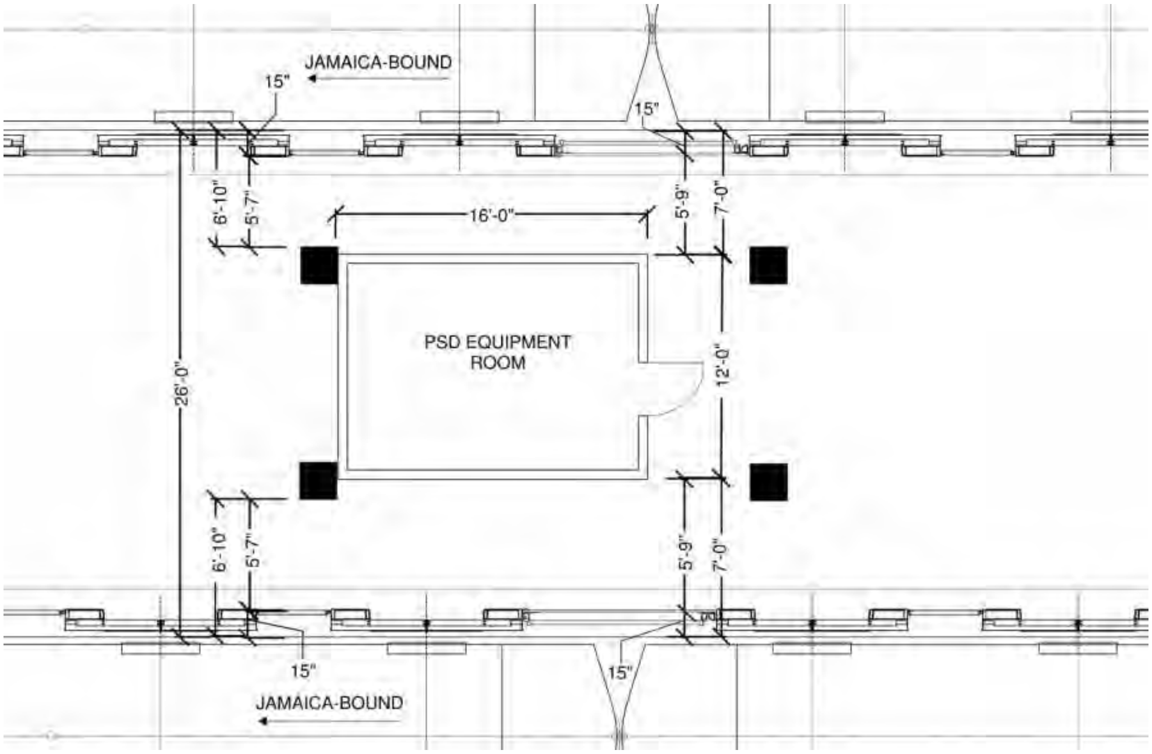

Figure 2 – PSD Equipment Room Detail – Coney Island-Stillwell Avenue Station

Track Layout

Tracks are mostly tangent with the exception of the tapered north-end of the platform. Thus, we are expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions. The 2012 NYCT conditions survey for this station could not be obtained at the time of drafting this report. However it should be noted this station underwent a major rehabilitation in 2005. It can be safely assumed that major reconstruction would be required to implement either a PSD or APG system at this station. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would be required for the installation of an APG system and PSD system. The APG due to its cantilevered configuration and the PSD due to there being no components above it to mount to provide support and stability.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: This station has a lot of natural daylight, however there are also linear fluorescent lights below the beams that run parallel to the platform. These beams are approximately 12'-0" high and 5'-0" from the edge of the platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 and Table 2 please see the Power Capacity Analysis for this station. MRN 058 has adequate capacity to support the implementation of a APG/PSD system only through the reserve system. The Normal EDR possesses inadequate capacity

Station (Reserve)
Power Capacity Analysis

NYCT Station MR Number	58
Station Name	Coney Island Stillwell / Surf Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	112.0
Apparent Power (kVA)	140.0
Station Peak Demand Load, Max Current, (A)	388.9
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	1022
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	179
Is Electrical Service Adequate?	Yes
Notes	This is for Reserve service only. This is based on assumption that each Service is separate.Reserve service has spare capacity. (Normal service has **NO** spare capacity). See Analysis (N) tab.

Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	This is for Normal service only. Station has (2) separate meter readings (not combined). Normal service has exceeded its service rating. **NO** additional load be connected to this normal service. See Analysis (R) tab.

Table 1. MRN 058 Normal Capacity Analysis

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached

ROM estimate. The total cost for this station (only the F-line platform edges and equipment room) is estimated to be $32.2M to install APGs and $41.0M to install PSDs (See Appendix E).

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

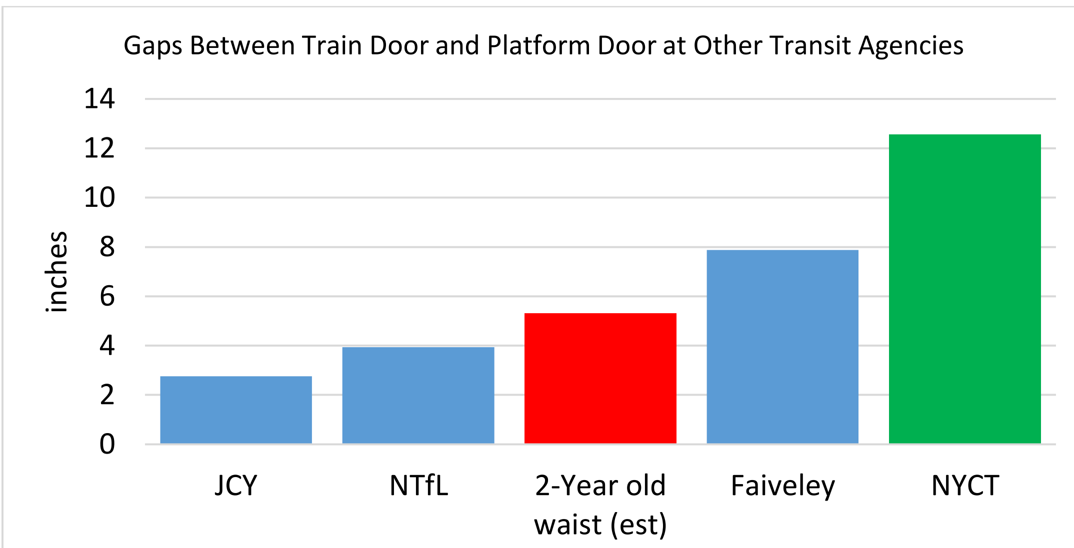

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

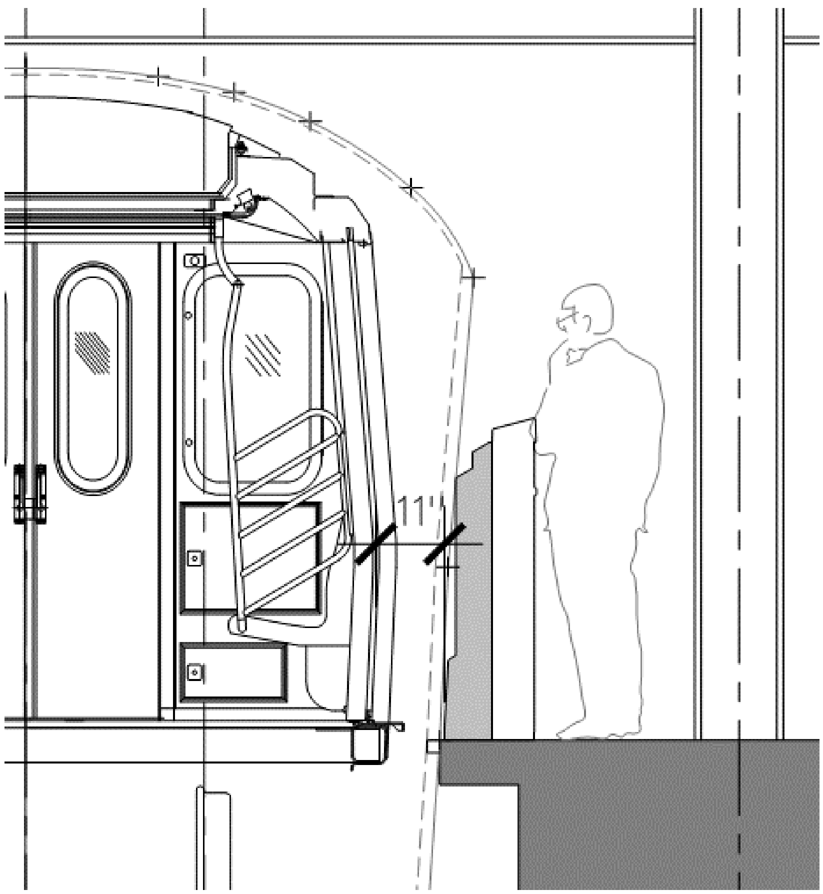

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

Impact per station

2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

Impact per station

3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

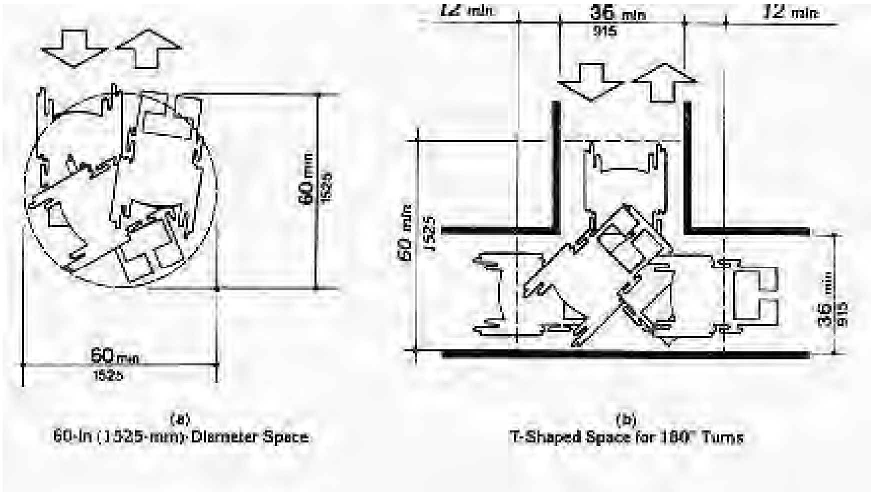
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

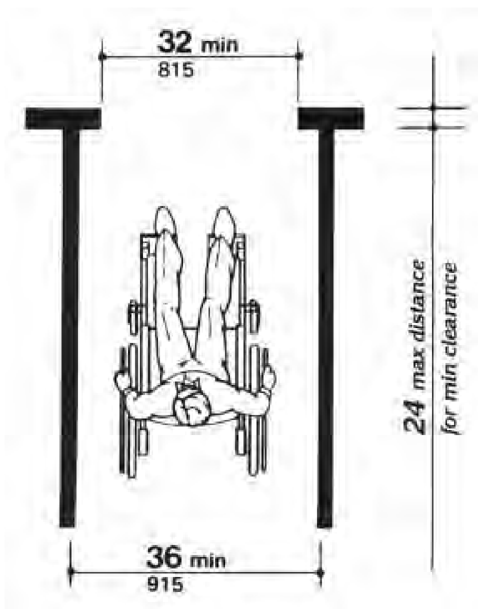


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

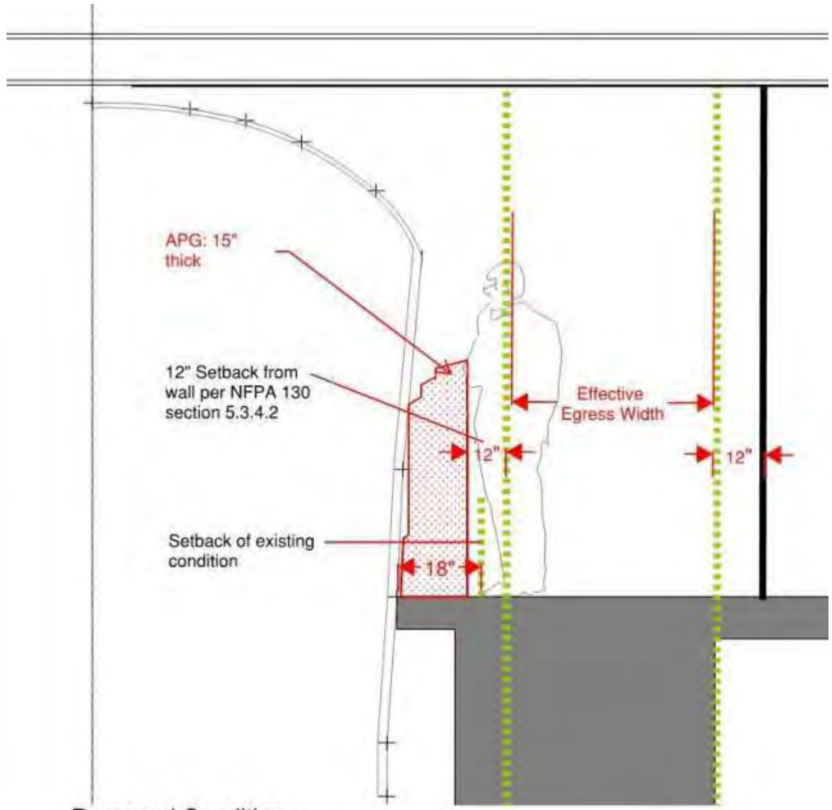
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

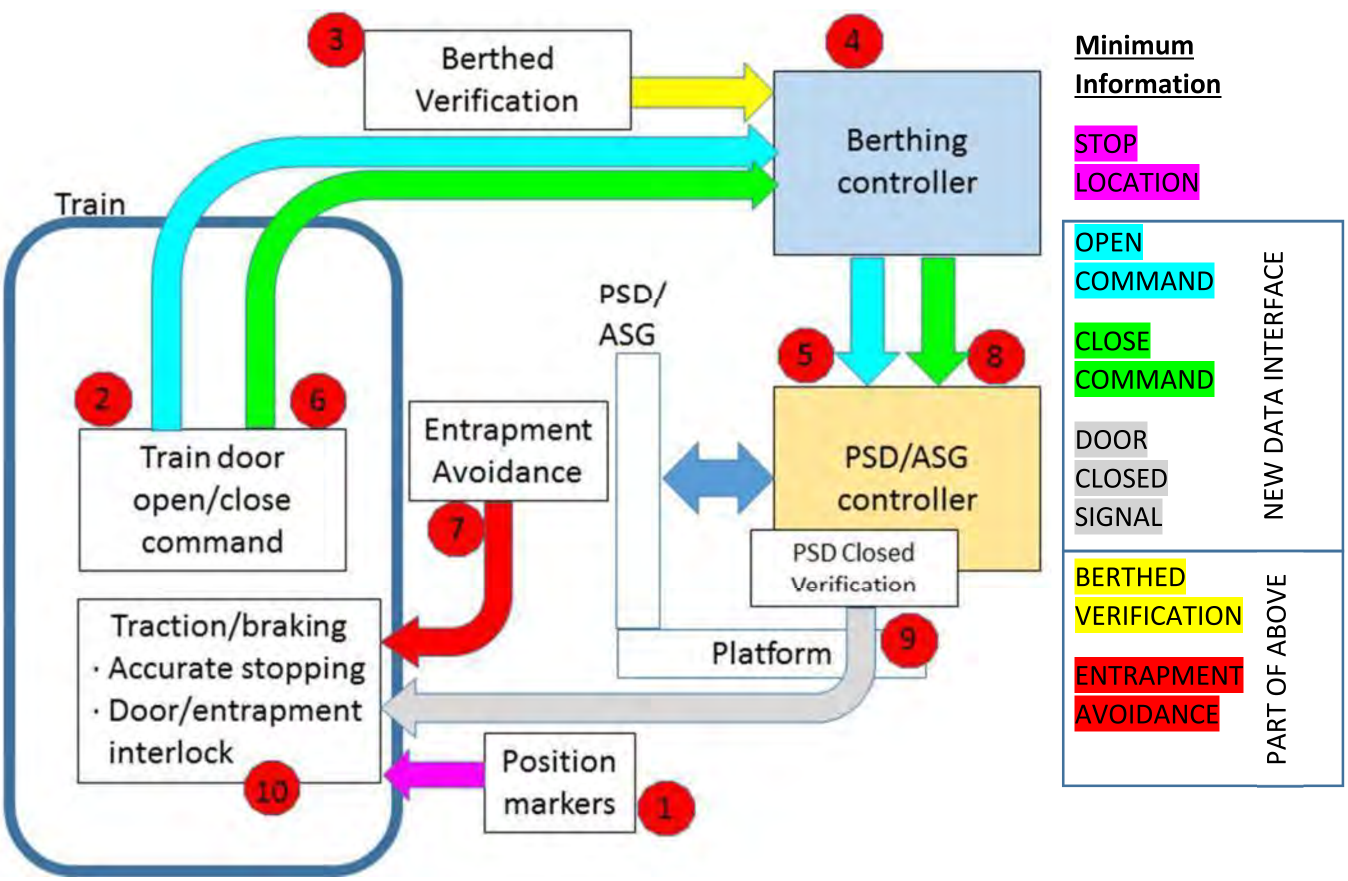
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

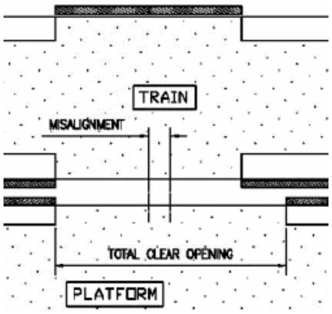
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

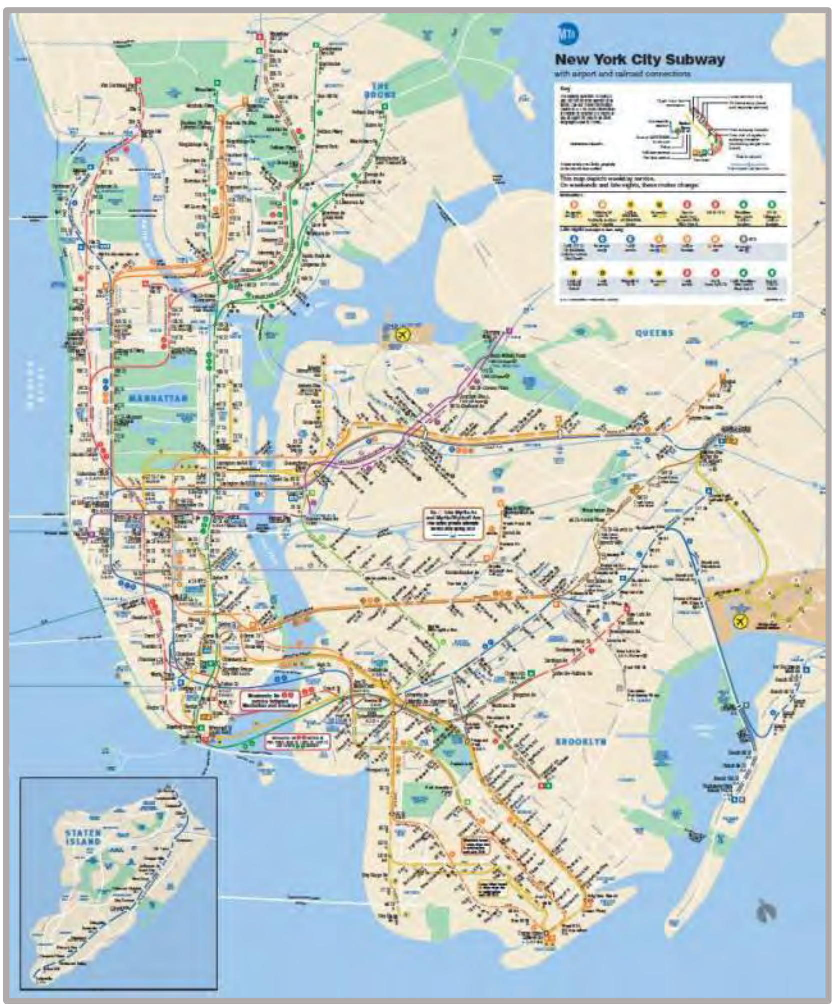


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.
