Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

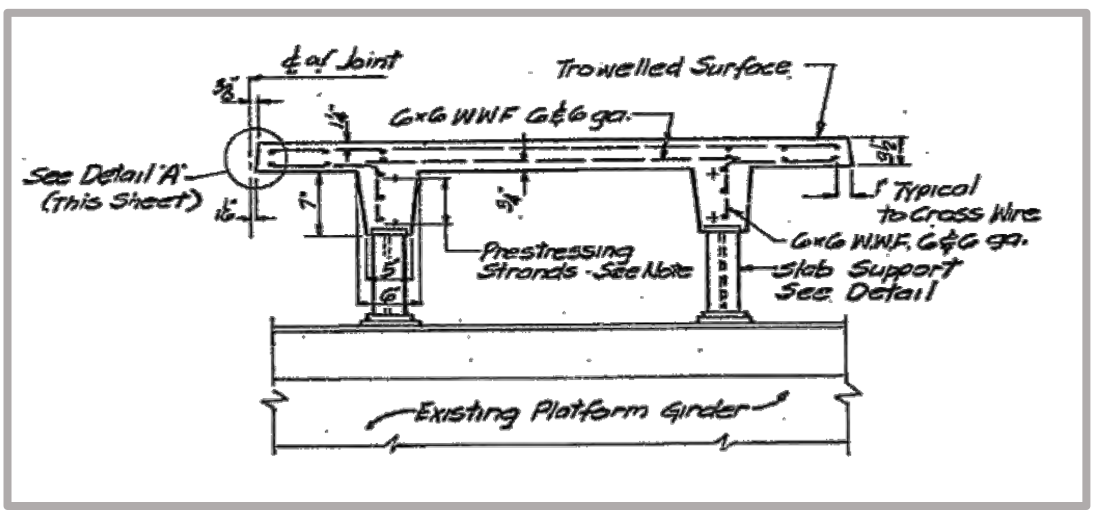

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

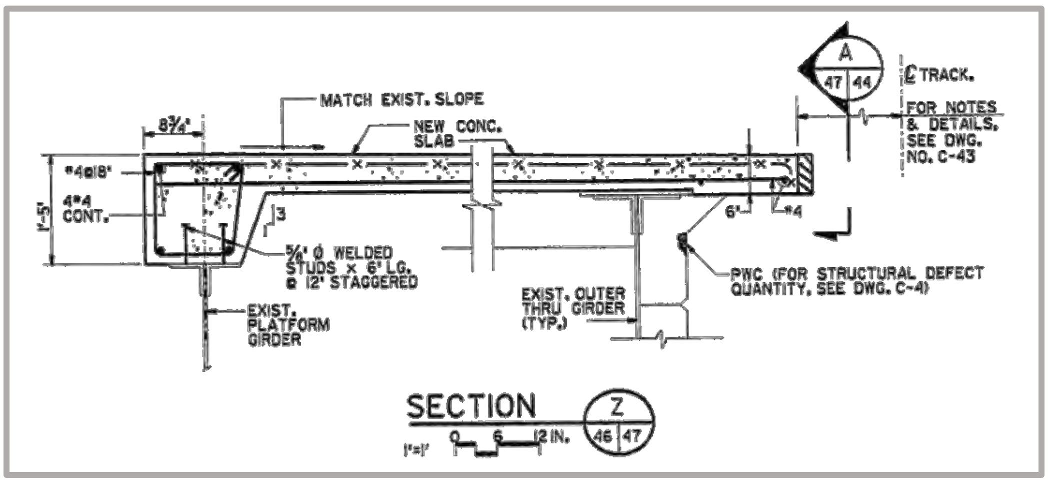

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2’-9”), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

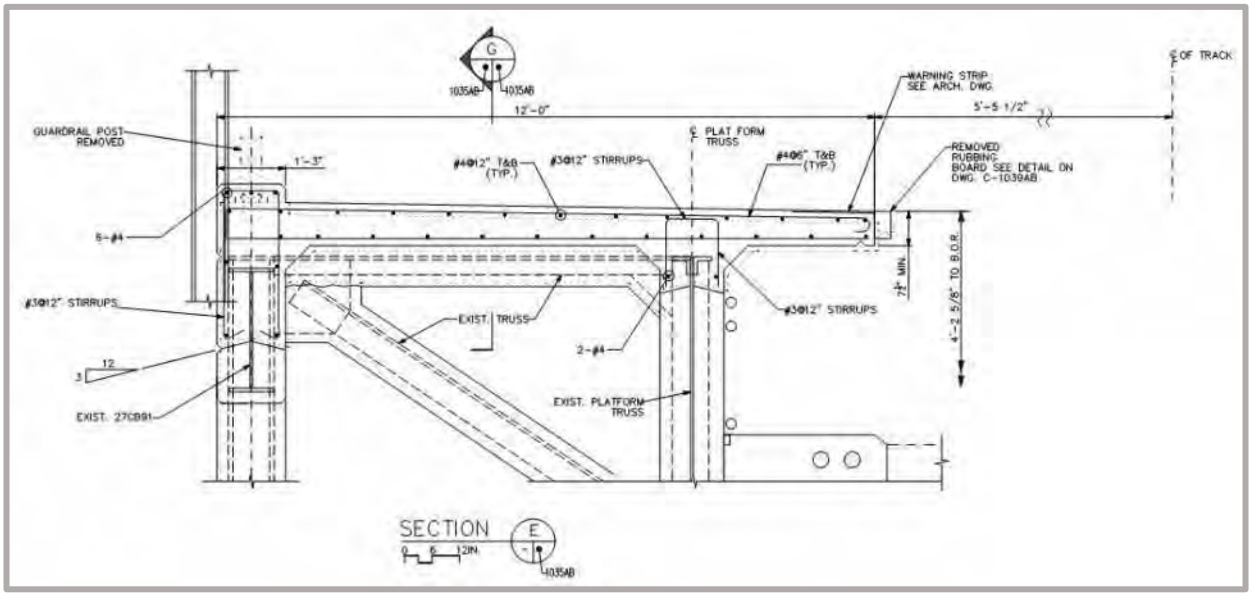

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

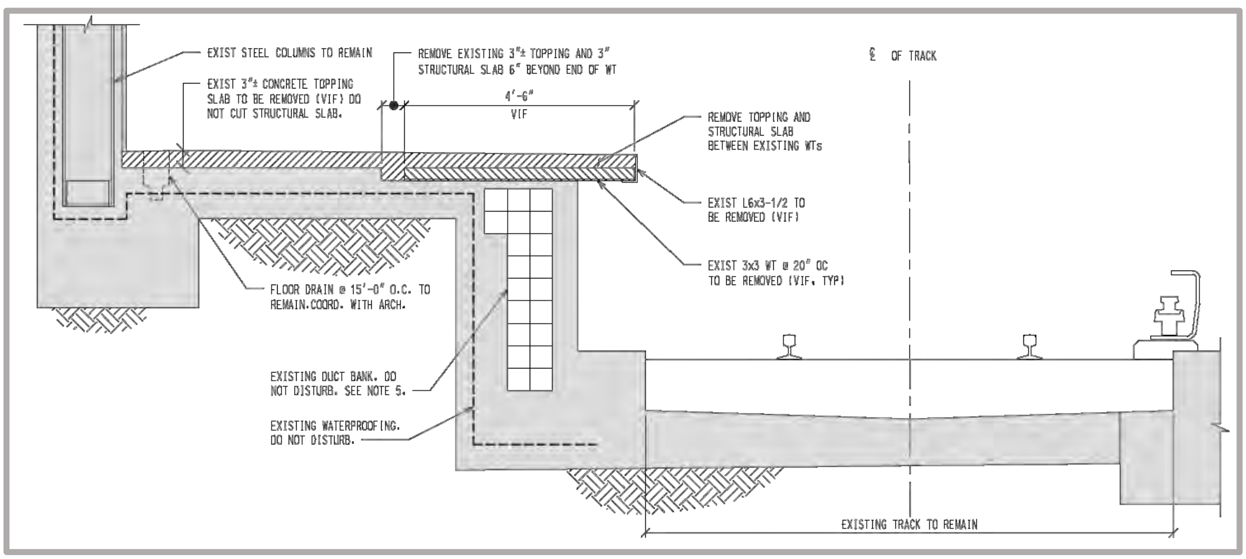

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

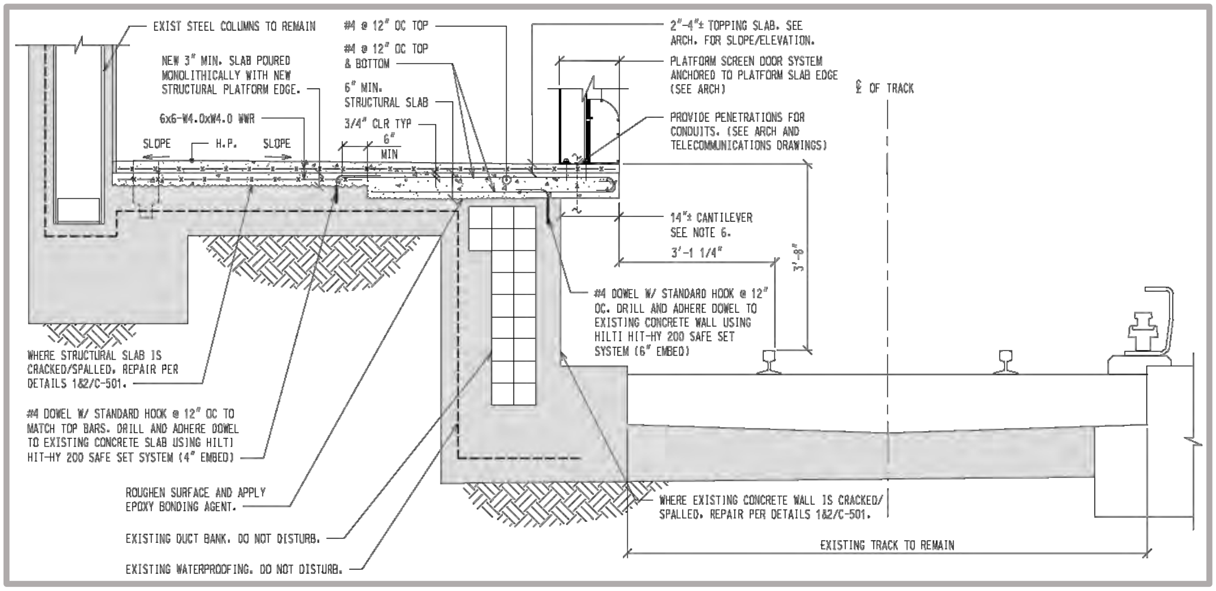

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

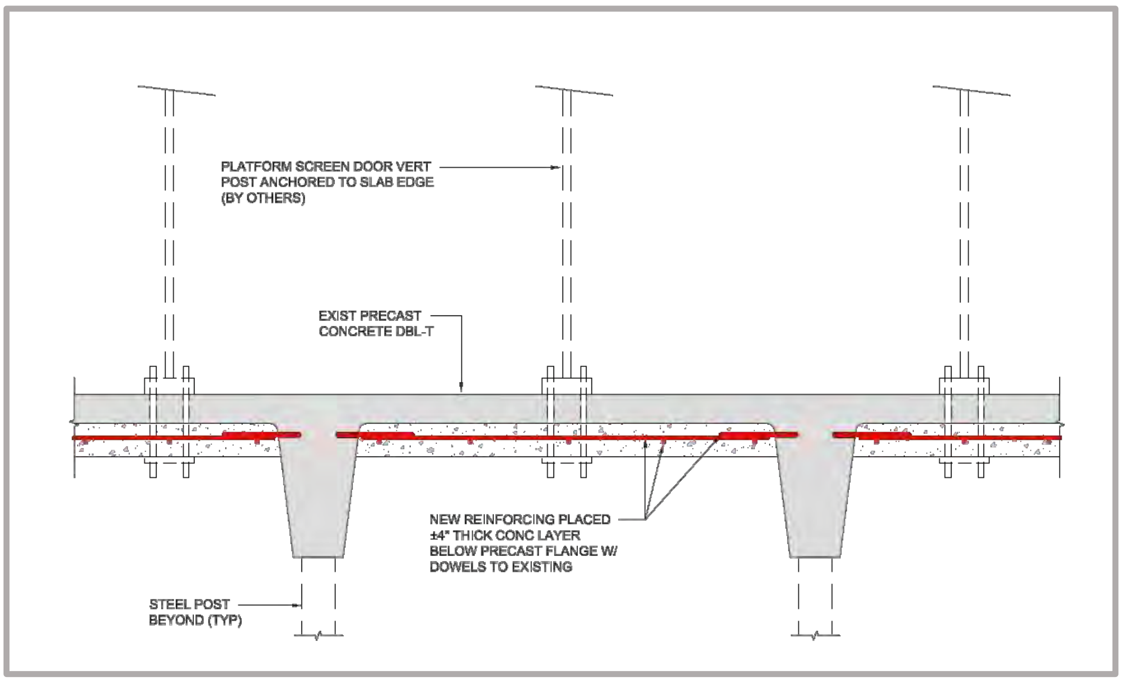

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

MTA/NYCT

October 4, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.2 In respect of the PSD option, only platforms that have not been upgraded in the recent past (assuming over the past two decades) will require platform edge replacement.
2.3 There are no special security requirements made necessary by installation of the APG system
2.4 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.5 This estimate does not provide for the replacement of Platform Edge Lighting
2.6 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

MTA/NYCT

October 4, 2018

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 *Given the limited time available, no drawings were developed to support this estimate.*

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: 21ST STREET - QUEENSBRIDGE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	607	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,222**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,222	LF	7	8,554
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,110	SF	12	73,320
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	123	CY	2,500	307,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,224	EA	25	30,600
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,224	EA	25	30,600
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,222	LF	95	116,090
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,222	LF	15	18,330
26	Remove existing platform tiles	1,222	LF	12	14,664
27	Sawcut existing topping concrete at perimeter of removal area	1,222	LF	5	6,110
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,332	SF	8	58,656
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 12'-6" wide strip	572	SF	8	4,576
30	New Work				
31	New concrete topping to match existing	1,222	SF	15	18,330
32	New concrete topping at ADA boarding area to match existing	572	SF	15	8,580

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: 21ST STREET - QUEENSBRIDGE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	41	LF	90	3,690
39	CMU Wall for equipment room	410	SF	45	18,450
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	189	SF	30	5,670
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	410	SF	40	16,400
45	Mosaic Band to match existing - Assuming 8" high	41	LF	120	4,920
46	Concrete cove to match existing	41	LF	20	820
47	Interior Wall Finish - Paint	410	SF	5	2,050
48	Allow for Misc. floor & ceiling finishes	189	SF	15	2,835
49	Allow for 4" thick concrete pads for equipment	47	SF	20	945
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,214	SF	750	1,660,500
61	Spare Parts - Approx. 10% of Material Cost	1	LS	226,290	226,290
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
71	Allow for conduit / cable runs for power and communications under platform edge	1,222	LF	60	73,320

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: 21ST STREET - QUEENSBRIDGE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
74	Power to PSD Room from EDR including track crossing if needed	250	LF	60	15,000
75	Reserve power to PSD Room from EDR including track crossing if needed	750	LF	60	45,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
79	MISC				
80	Testing and commissioning	1	LS	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	2,000	Hrs	160	319,860
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: ROOSEVELT ISLAND

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	615	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,230	LF	7	8,610
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,230	LF	95	116,850
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
26	Remove existing platform tiles	1,230	LF	12	14,760
27	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 12' wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,230	SF	15	18,450
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920

STATION: LEXINGTON AVE - 63RD ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	615	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,230	LF	7	8,610
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,230	LF	95	116,850
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
26	Remove existing platform tiles	1,230	LF	12	14,760
27	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 21'-6" wide strip at ADA boarding area	418	SF	8	3,344
30	New Work				
31	New concrete topping to match existing	1,230	SF	15	18,450
32	New concrete topping at ADA boarding area to match existing	418	SF	15	6,270

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: YORK ST.

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,320**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 20'-0" wide strip at ADA boarding area	352	SF	8	2,816
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800
32	New concrete topping at ADA boarding area to match existing	352	SF	15	5,280

Tier 2-3 Report on Feasibility of Platform Edge Barriers for F Line Stations

4-Oct-18

STATION: YORK ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [12'-0" x 16'-0"]**				
37	Build off existing Paid Area Slab; 3 Walls only		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	44	LF	90	3,960
39	CMU Wall for equipment room	440	SF	45	19,800
40	Vertical connections with existing structure	20	LF	25	500
41	Fire rated door including frame & hardware	1	EA	2,500	2,500
42	Exterior wall finish				
43	Ceramic Tiling to match existing	440	SF	40	17,600
44	Mosaic Band to match existing - Assuming 8" high	44	LF	120	5,280
45	Concrete cove to match existing	44	LF	20	880
46	Interior Wall Finish - Paint	440	SF	5	2,200
47	Allow for Misc. floor & ceiling finishes	192	SF	15	2,880
48	Allow for 4" thick concrete pads for equipment	48	SF	20	960
49	Allowance for Mechanical Scope	1	LS	40,000	40,000
50	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
51	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
52	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
53					
54	**Automatic Platform Gates [APGs] - 4'-6" High**				
55	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
56	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
57	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
58	Platform End Gates (PEGs)	4	EA	13,000	52,000
59	Fixed Panels including framing and support; 4'-6" High	2,655	SF	750	1,991,250
60	Spare Parts - Approx. 10% of Material Cost	1	LS	246,135	246,135
61	Testing and commissioning	800	HRS	160	127,944
62	Product Warranty	1	LS	1,000,000	1,000,000
63	Allowance for Braille Signage	80	EA	2,500	200,000
64					
65	**Electrical**				
66	Electrical Upgrades				
67	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
68	Power and Lighting				
69	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
70	Allow for conduit / cable runs for power and communications under platform edge	1,320	LF	60	79,200

STATION: STILLWELL AVE - CONEY ISLAND

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [TRACK 5] =	640	LF		
5	LENGTH OF THE PLATFORM EDGE [TRACK 6] =	640	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,280**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,280	LF	7	8,960
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,400	SF	12	76,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	129	CY	2,500	322,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,282	EA	25	32,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,282	EA	25	32,050
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,280	LF	95	121,600
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,280	LF	15	19,200
26	Remove existing platform tiles	1,280	LF	12	15,360
27	Sawcut existing topping concrete at perimeter of removal area	1,280	LF	5	6,400
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,680	SF	8	61,440
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 27'-0" wide strip at ADA boarding area	660	SF	8	5,280
30	New Work				
31	New concrete topping to match existing	1,280	SF	15	19,200
32	New concrete topping at ADA boarding area to match existing	660	SF	15	9,900

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘M’ LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: December 5, 2018

Table of Contents

0.0 Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 36 newly evaluated stations, 32 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the PSD platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the M line service and several overlapping services on the B Division will remain incompatible even after 2032. The M is an eight-car train, whereas the E, F, R lines are ten-car trains. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The M train cannot be extended to a ten-car length because all the station stops in Brooklyn feature station platforms of an eight-car length. Please see the diagrams in Figure 1 below.

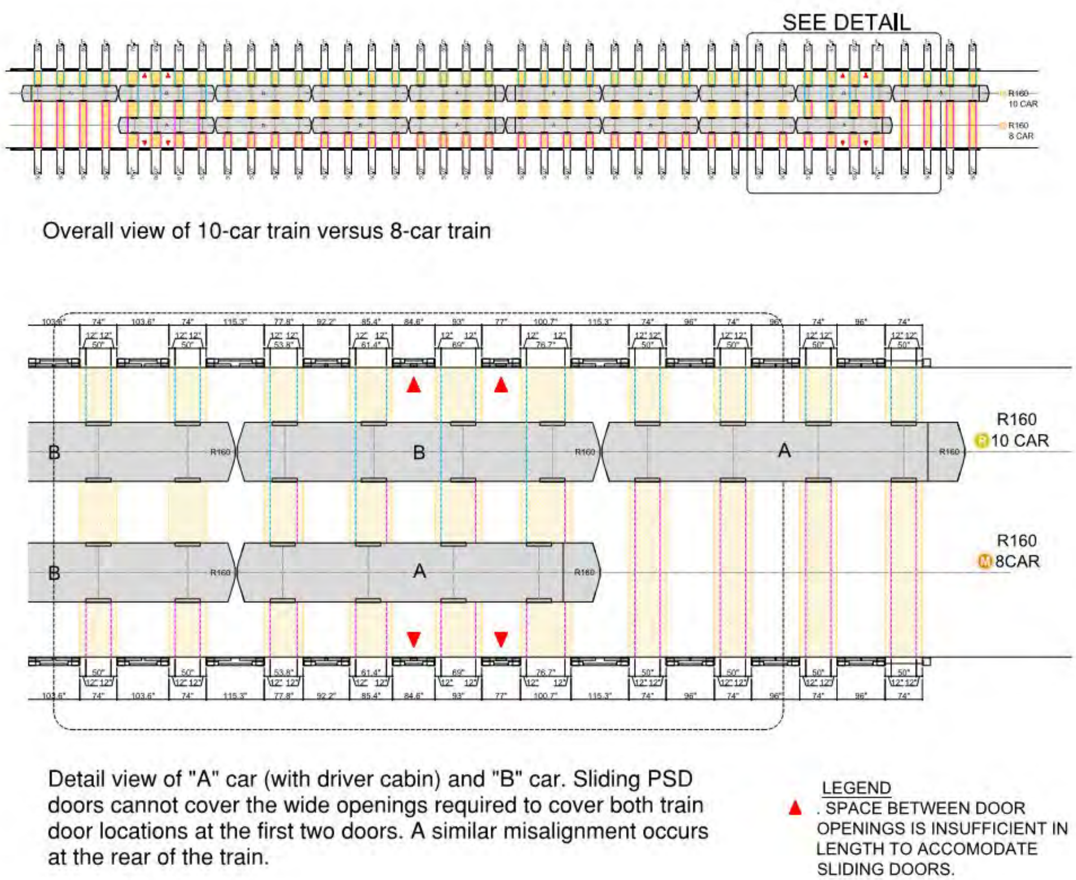

***Figure 1** – Ten-car vs. eight-car train Comparison of door geometry*

Note that a determination full feasibility will require two additional steps

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 11% of the 'M' Line stations. Total implementation cost would be $111.5M for APGs and $138.9M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 4 feasible stations, the aggregate annual maintenance cost would be $3.7M.

Table of Contents

Summary Table

1.0 Station Assessments

1.01 – MRN 097 | Myrtle Avenue-Broadway Station

Summary: *Myrtle Avenue-Broadway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 31" (see figure 1).*

Description

Myrtle Avenue-Broadway Station is an elevated station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 14'-0" throughout. There are three staircases on each of the platforms. Columns are spaced 15'-4" on center and flank the staircases on both sides. Currently the stair barrier and columns measure 46" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 31" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
Myrtle Avenue-Broadway Station

1.02 – MRN 098 | Flushing Avenue Station

Summary: *Flushing Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

Flushing Avenue Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-2" throughout. There are two staircases along each of the platforms located at 40" from the platform edge. With the implementation of a platform edge barrier this width would be reduced to 25", which is not compliant with the ADA minimum of 36". See figure 1 below.

Figure 1 *– Non-Compliant ADA condition*
Flushing Avenue Station

1.03 – MRN 099 | Lorimer Street Station

Summary: *Lorimer Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

Lorimer Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-4" throughout. There are two staircases along each of the platforms located at 40" from the platform edge. With the implementation of a platform edge barrier this width would be reduced to 25", which is not compliant with the ADA minimum of 36". See figure 1 below.

***Figure 1** – Non-Compliant ADA condition*
Lorimer Street Station

1.04 – MRN 100 | Hewes Street Station

Summary: *Hewes Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

Hewes Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-8" throughout. There are two staircases along each of the platforms located at 40" from the platform edge. With the implementation of a platform edge barrier this width would be reduced to 25", which is not compliant with the ADA minimum of 36". See figure 1 below.

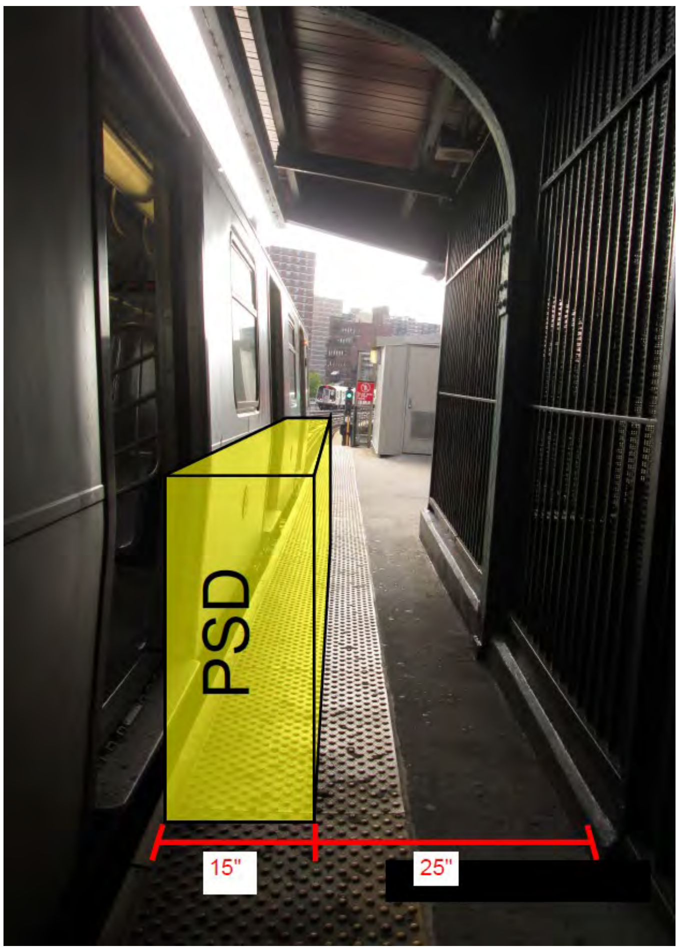

Figure 1 *– Non-Compliant ADA condition*
Hewes Street Station

1.05 – MRN 101 | Marcy Avenue Station

Summary: *Marcy Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description

Marcy Avenue Station is an elevated station consisting of two side platforms. The platform widths are approximately 10'-0". The platforms are straight with a row of a columns in line with the wind screen, which support the station canopy. The canopy covers half of the platform length. See figure 1 & 2 for reference.

Figure 1 *– General Station condition*
Marcy Avenue Station

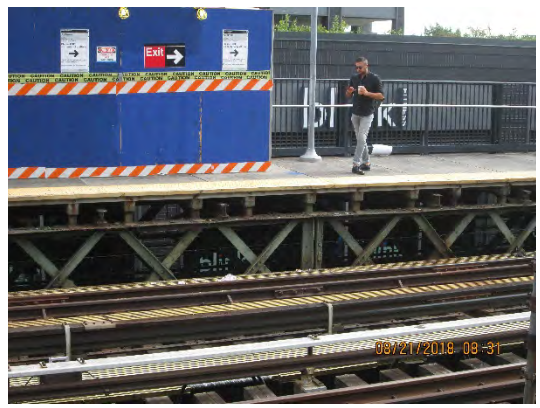

Figure 2 *– Precast Slab*
Marcy Avenue Station

1.06 – MRN 108 | Middle Village Metropolitan Avenue Station

Summary: *Middle Village Metropolitan Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Middle Village Metropolitan Avenue Station is an embankment station with one center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. Columns are centered throughout the length of the platform and are spaced 30'-0 apart on center. Column faces measure approximately 6'-1" from the platform edge. The platform width is approximately 13'-6" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the south end of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are nearly tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey information was not ascertainable at the time of drafting this report, where on a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair. Any platform edge with a rating above 2.5 requires platform rehabilitation regardless of if an APG or PSD system is utilized.

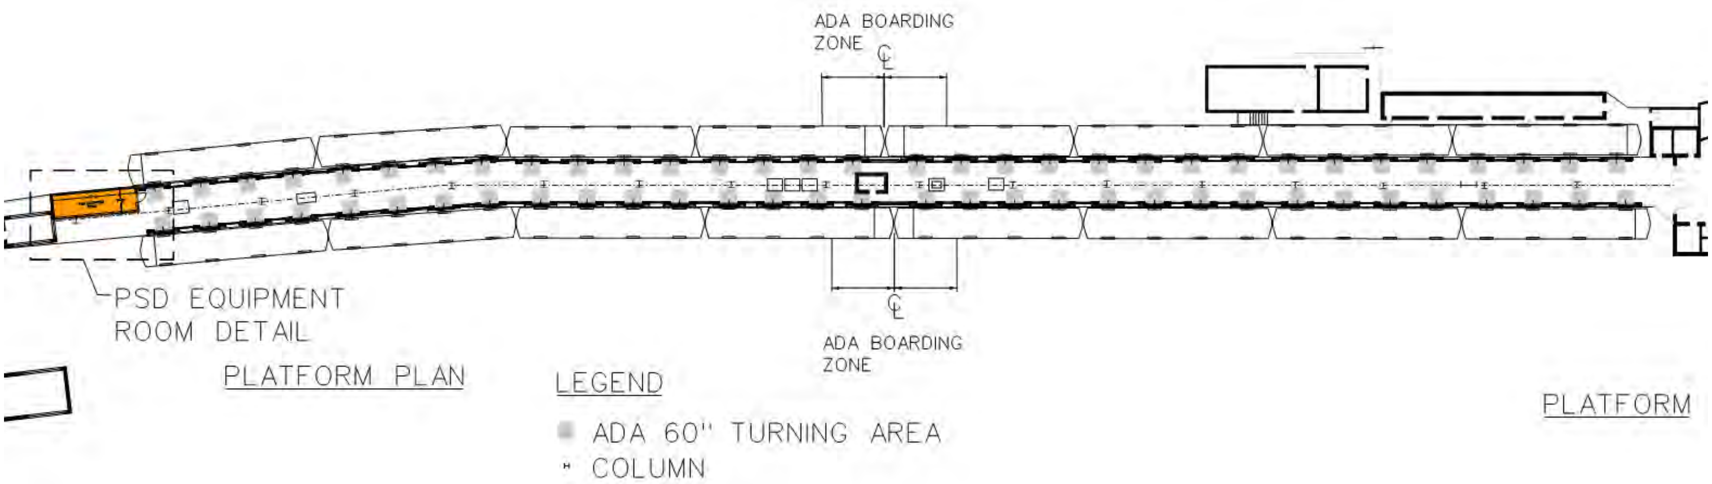

***Figure 1** – Overall Station Plan*
Middle Village Metropolitan Avenue Station

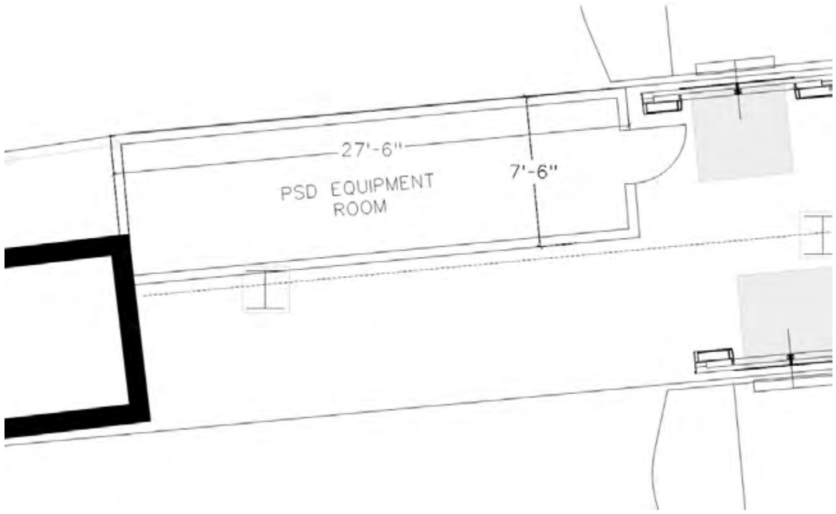

Figure 2 *– PSD Equipment Room 1 Detail*
Middle Village Metropolitan Avenue Station

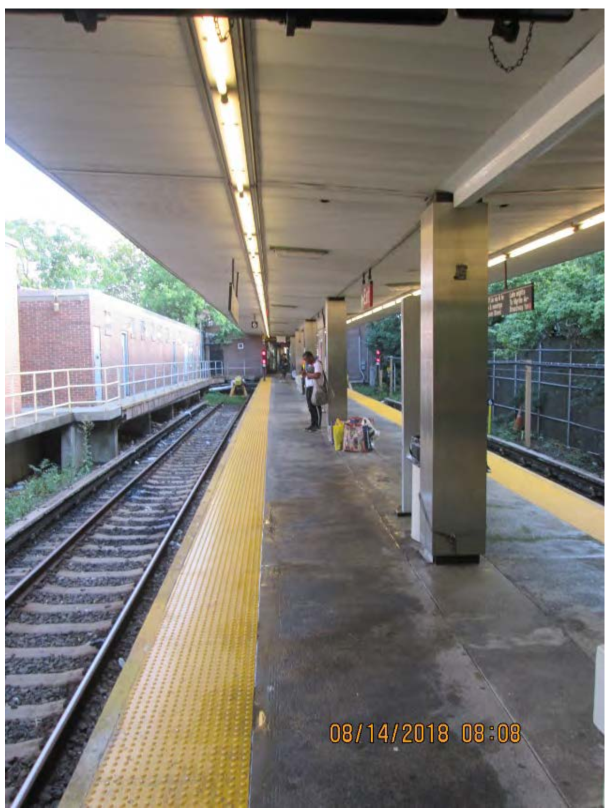

Figure 3 *– Typical platform view*
Middle Village Metropolitan Avenue Station

Platform obstructions within 5' of edge: None

Lighting:
Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis

Station Name	Middle Village Metropolitan Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	79.2
Apparent Power (kVA)	99.0
Station Peak Demand Load, Max Current, (A)	275.0
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.4
Total Load (Station Peak + PSD), (A)	440
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	360
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**.

Power Capacity Analysis

Station Name	Middle Village Metropolitan Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	37.2
Apparent Power (kVA)	46.5
Station Peak Demand Load, Max Current, (A)	129.2
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.4
Total Load (Station Peak + PSD), (A)	295
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	505
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Reserve service**.

***Table 2**. Reserve Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.9M to install APGs and $36.0M to install PSDs (See Appendix E)

1.07 – MRN 109 | Fresh Pond Road Station

Summary: *Fresh Pond Road Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Fresh Pond Road Station is an elevated station with one center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. Columns are located throughout the length of the canopy in two rows and are spaced approximately 22'-0" apart on center. The canopy covers approximately 2/3 of the platform length. Column faces measure approximately 4'-0" from the platform edge. The platform width is approximately 26'-0" throughout except for a taper at the south end where the platform measures 17'-0". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The installation of full height PSDs beyond the canopy will require an overhead support structure.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. At parts of the platform not covered by a canopy, minimal overhead structures would be required to support cameras and sensors.

Equipment Room

The equipment room can be located at the north end of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are nearly tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

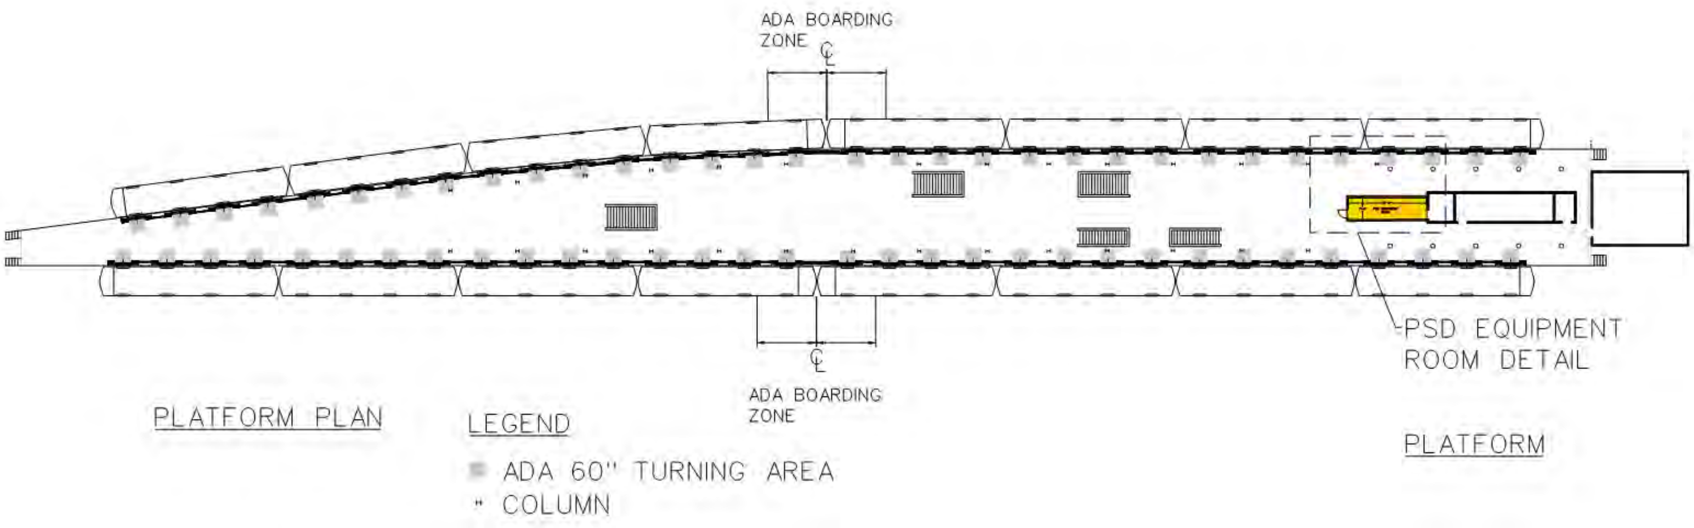

***Figure 1** – Overall Station Plan*
Fresh Pond Road Station

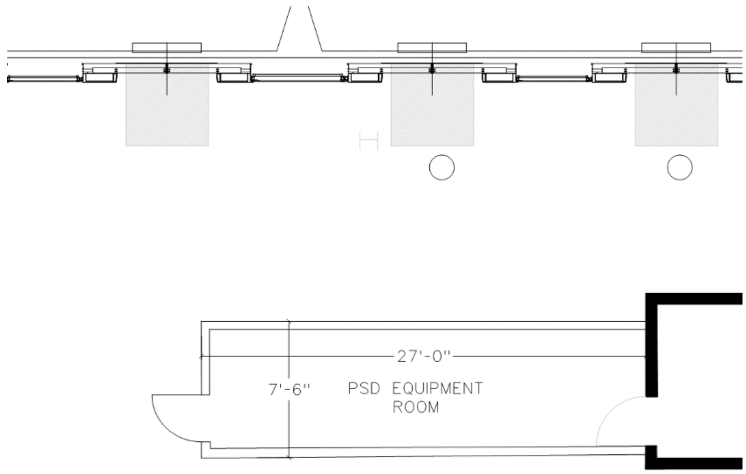

Figure 2 *– PSD Equipment Room 1 Detail*
Fresh Pond Road Station

Figure 3 *– Typical platform view*
Fresh Pond Road Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing columns which obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.3M to install APGs and $34.0M to install PSDs (See Appendix E)

1.08 – MRN 110 | Forest Avenue Station

Summary: *Forest Avenue 67th Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Forest Avenue Station is an elevated station with one center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. Columns are located throughout the length of the platform in two rows and are spaced approximately 25'-0" apart on center. Column faces measure approximately 2'-6" from the platform edge. The platform width is approximately 19'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The installation of full height PSDs beyond the canopy will require an overhead support structure.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. At parts of the platform not covered by a canopy, minimal overhead structures would be required to support cameras and sensors.

Equipment Room

The equipment room can be located at the north end of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

Figure 3 *– Typical platform view*
Forest Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing columns which obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Forest Avenue 67th Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	24.0
Apparent Power (kVA)	30.0
Station Peak Demand Load, Max Current, (A)	83.3
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.4
Total Load (Station Peak + PSD), (A)	249
Station Service Power Capacity, (Main SB or SG Rating), (A)	400
Service Spare Capacity, (A)	151
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 400A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.3M to install APGs and $33.9M to install PSDs (See Appendix E)

Table of Contents

1.09 – MRN 111 | Seneca Avenue Station

Summary: *Seneca Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 17" (see figure 1).*

Description

Seneca Avenue Station an elevated station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platforms is approximately 15'-0" throughout. There are two staircases on the platform, located a minimum of 32" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 17" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

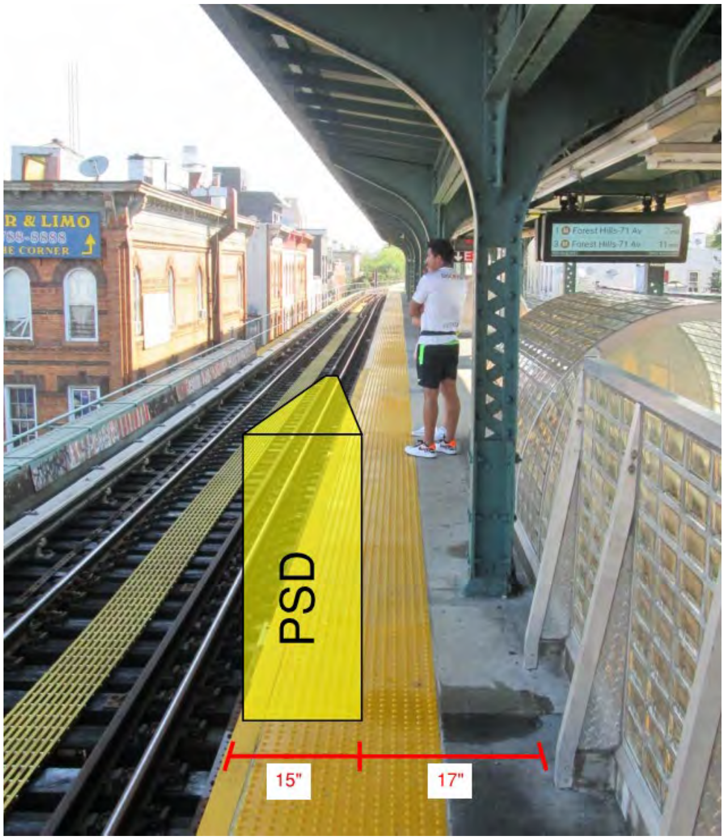

Figure 1 *– Non-Compliant ADA condition*
Seneca Avenue Station

1.10 – MRN 112 | Myrtle/Wyckoff Avenue Station

Summary: *Myrtle/Wyckoff Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Information regarding electrical capacity was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

Myrtle/Wyckoff Avenue Station is an elevated station with one center / island platform **(see Figure 1)**. The platform structure is cast-in-place concrete. Columns are located throughout the length of the platform in four rows and are spaced approximately 20'-0" apart on center. Column faces measure approximately 2'-6" from the platform edge. The platform width is approximately 15'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The installation of full height PSDs beyond the canopy will require an overhead support structure.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. At parts of the platform not covered by a canopy, minimal overhead structures would be required to support cameras and sensors.

Equipment Room

The equipment room can be located at the west end of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last ten years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

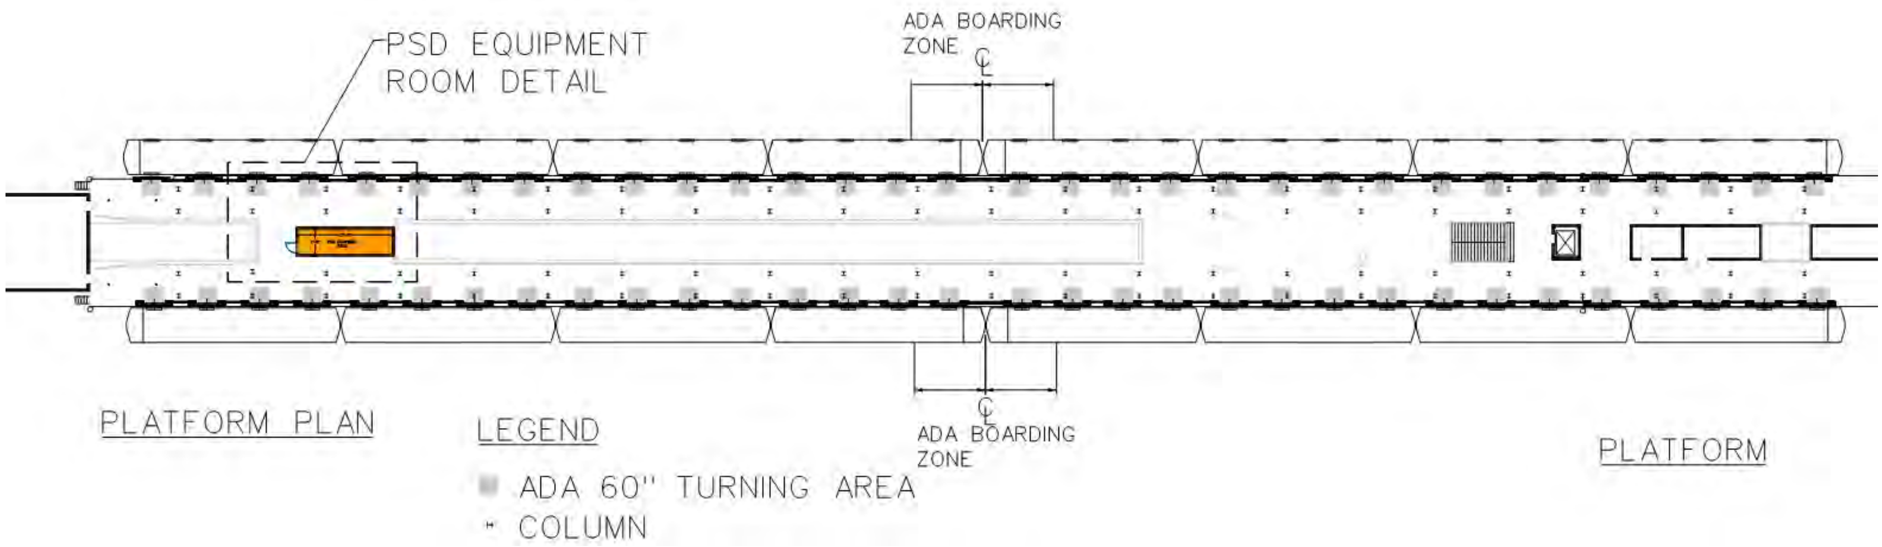

Figure 1 – Overall Station Plan
Myrtle/Wyckoff Avenue Station

Myrtle/Wyckoff Avenue Station

Figure 3 *– Typical platform view*
Myrtle/Wyckoff Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; perpendicular to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.0M to install APGs and $35.0M to install PSDs (See Appendix E)

Table of Contents

1.11 – MRN 113 | Knickerbocker Station

Summary: *Knickerbocker Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 17" (see figure 1).*

Description

Knickerbocker Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-0" throughout. There is one staircase along each of the platforms located at 34" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 17" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 below.

Figure 1 *– Non-Compliant ADA condition*
Knickerbocker Avenue Station

1.12 – MRN 114 | Central Avenue Station

Summary: *Central Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 19" (see figure 1).*

Description

Central Avenue Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-0" throughout. There is one staircase along each of the platforms located at 34" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 19" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 below.

Figure 1 *– Non-Compliant ADA condition*
Central Avenue Station

Table of Contents

1.13 – MRN 233 | Essex Street / Delancey Street Station

Summary: *Essex / Delancey Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at one stair as the remaining width would be 9" (see figure 1). (Note: this report examines only the Essex Street portion of the station; See the F-line report for the Delancey Station)*

Description

Essex / Delancey Station is a below-grade station with straight side and island platforms. The platform structures are cast-in-place concrete. The width of both platforms is approximately 12'-8". Columns are spaced 15'-0" on center with faces between 1'-8" and 3'-0" from the platform edge. A stairway is located 24" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 9" would not allow for ADA compliant wheelchair movement nor normal passenger movement. (see figure 1).

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for <u>Tier 2 Stations'</u> screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for <u>Tier 3 Stations</u> will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies

Assessment Factors General Factors	Specific Subfactors	PSDs	APGs	RPSDs	Grading system
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

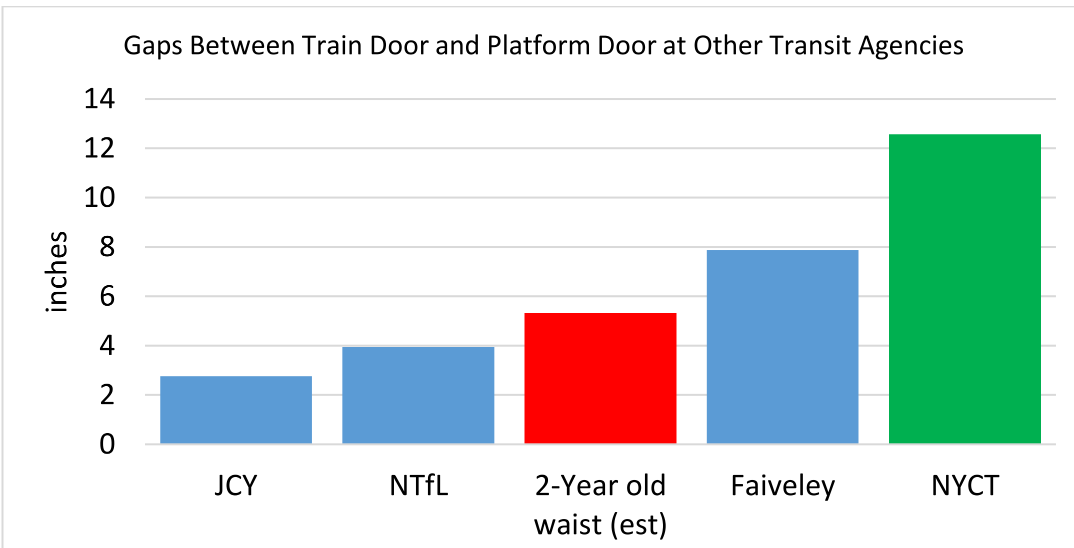

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

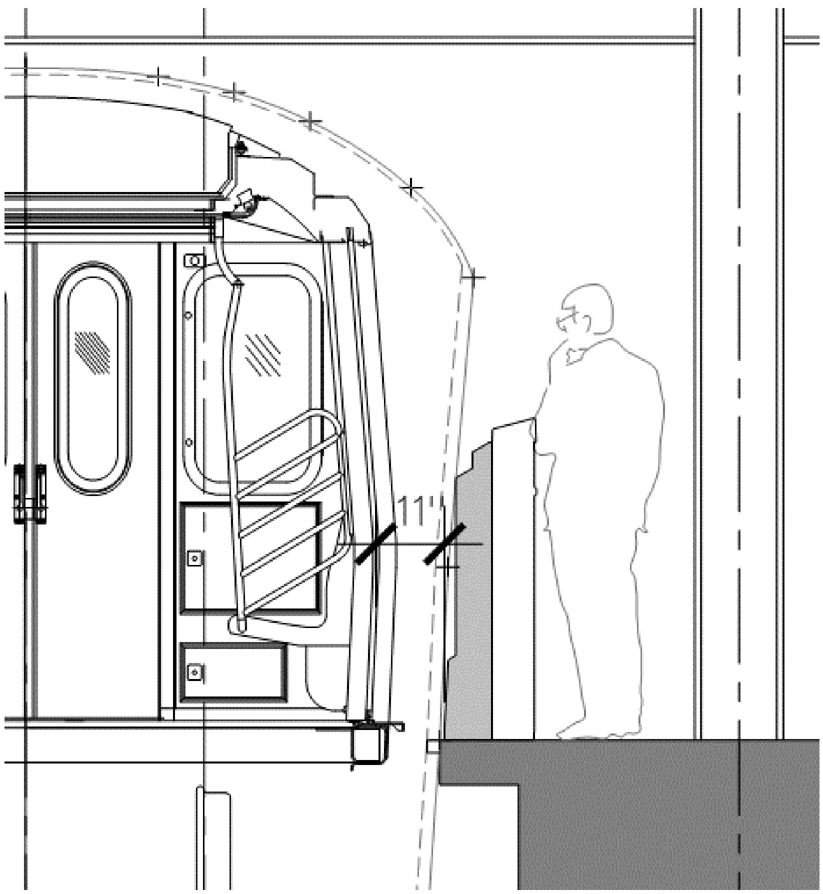

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	**3rd Ave.**	**6th Ave.**	**14 St / Union Square**	**1st Ave.**
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

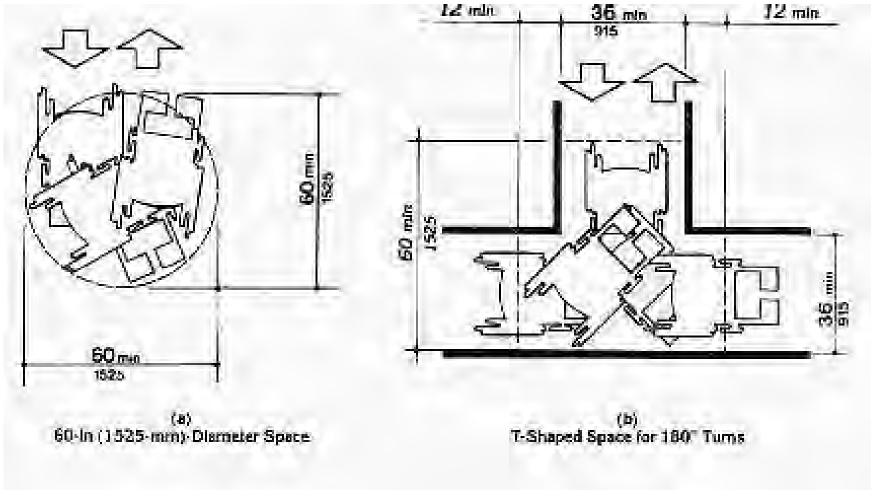
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

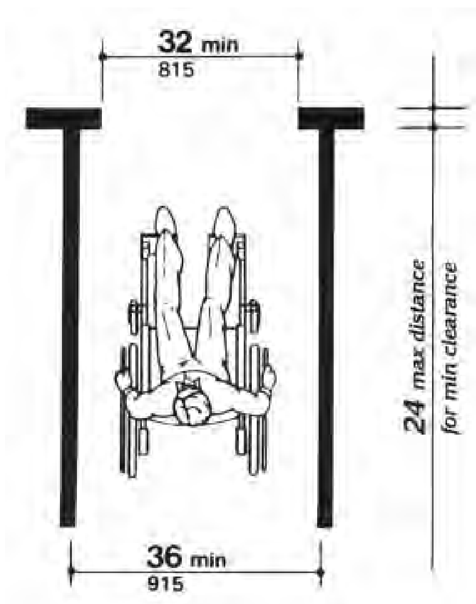


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

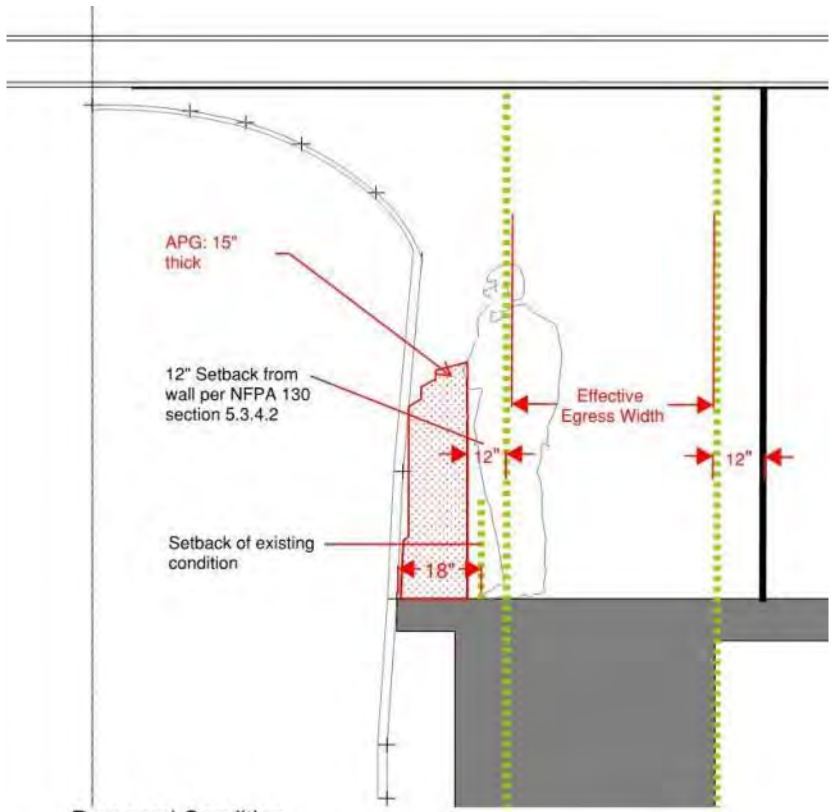
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents

Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

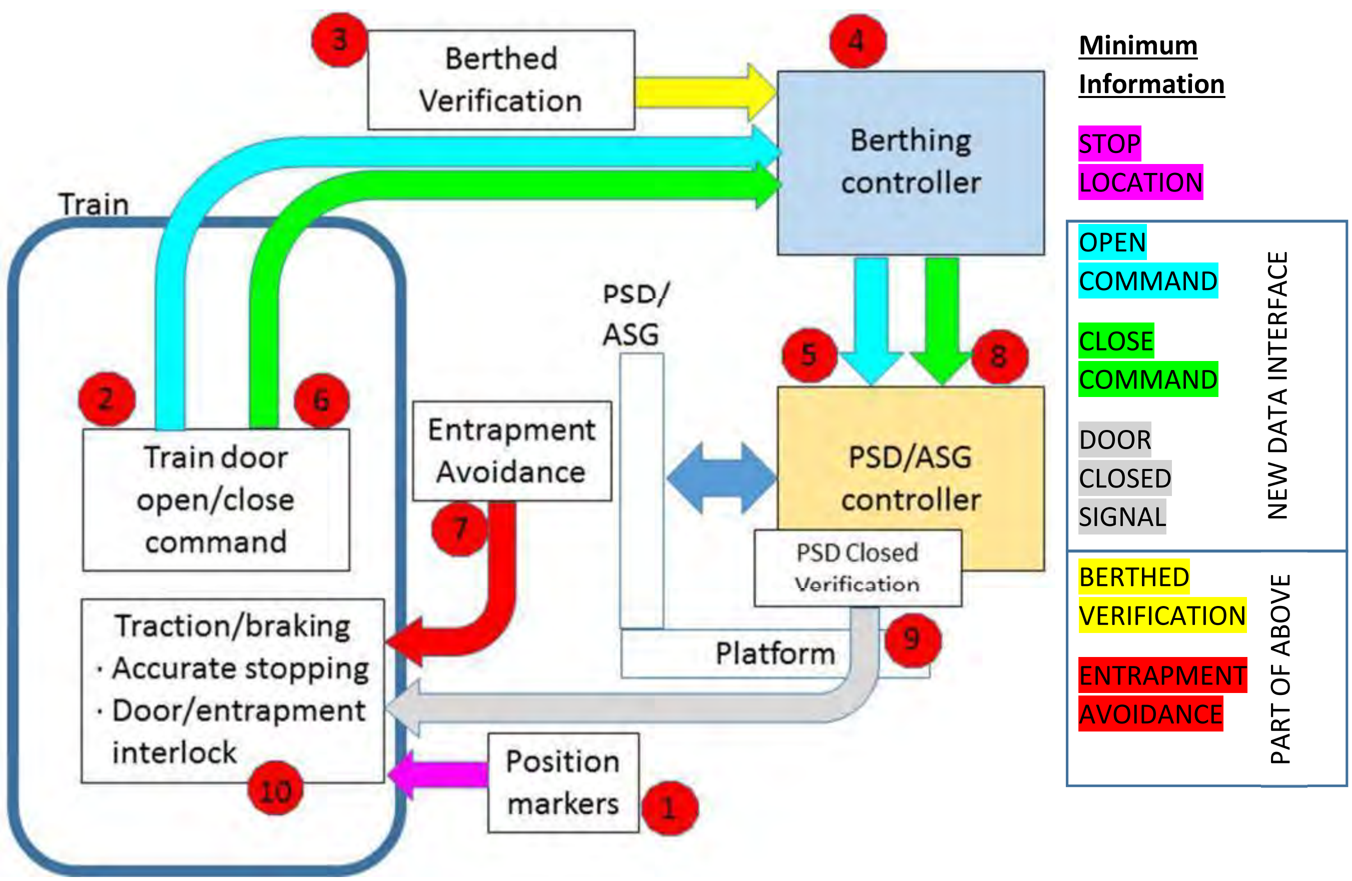
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

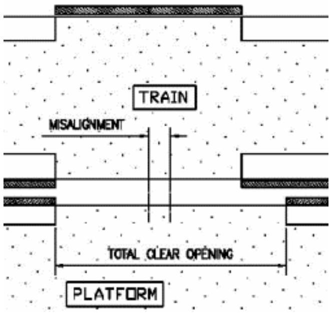
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

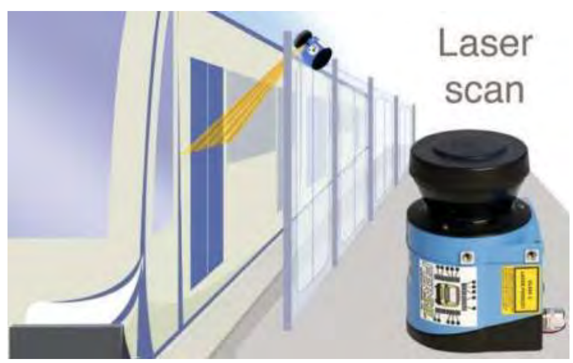
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

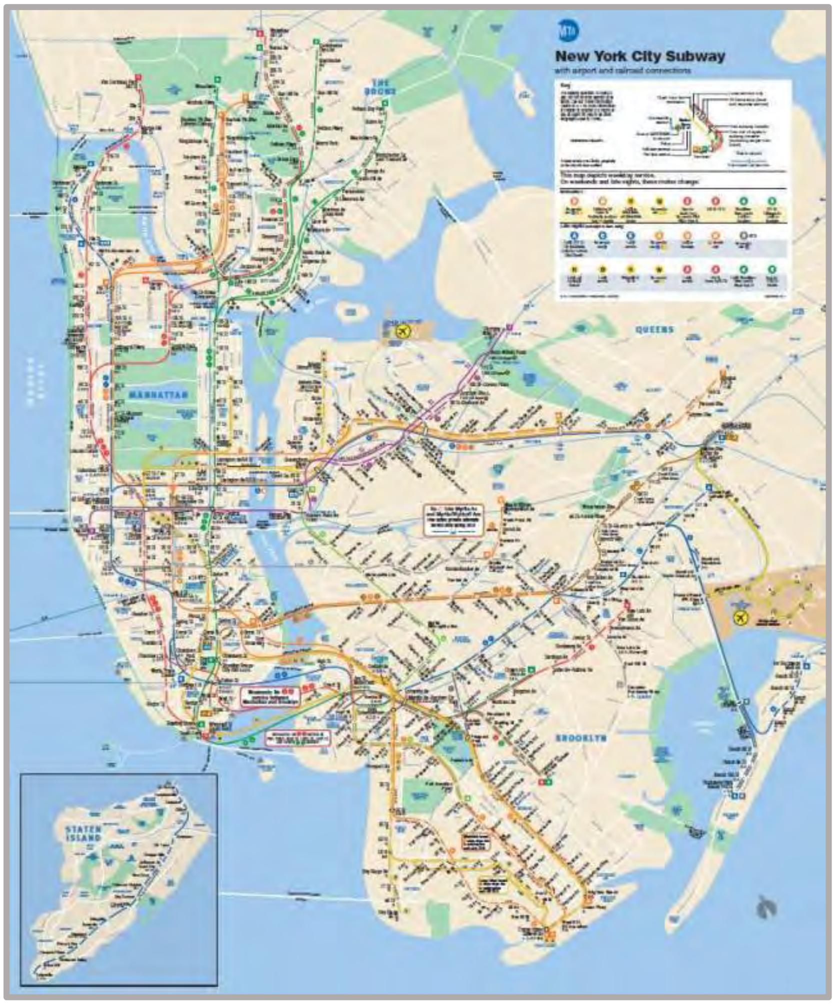


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

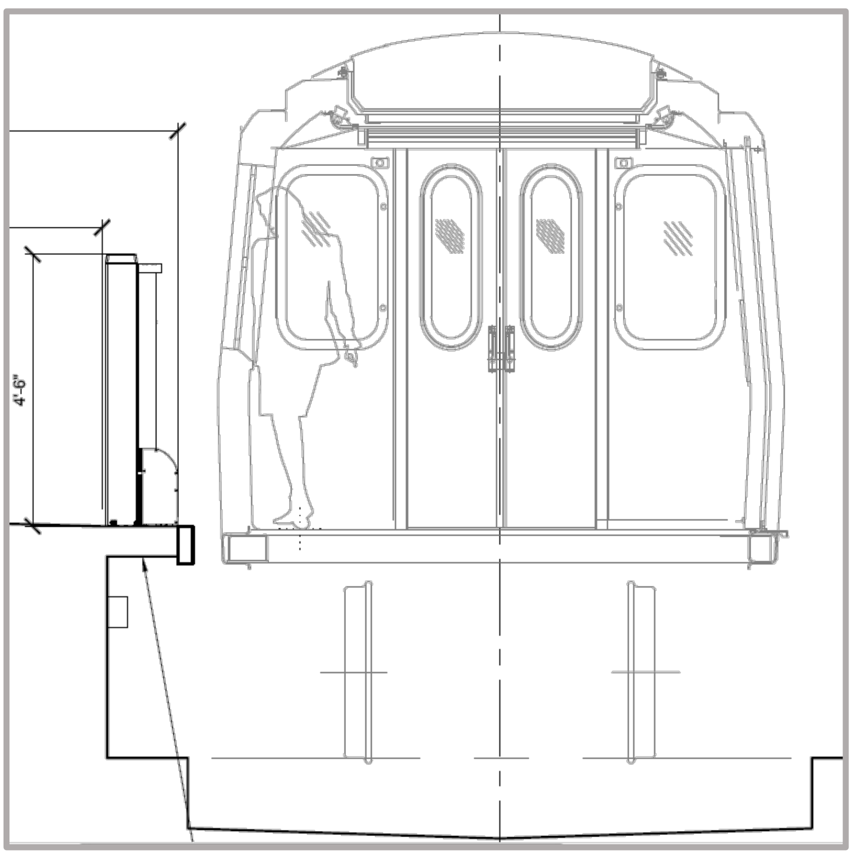

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 $lbs/ft.^2$ (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

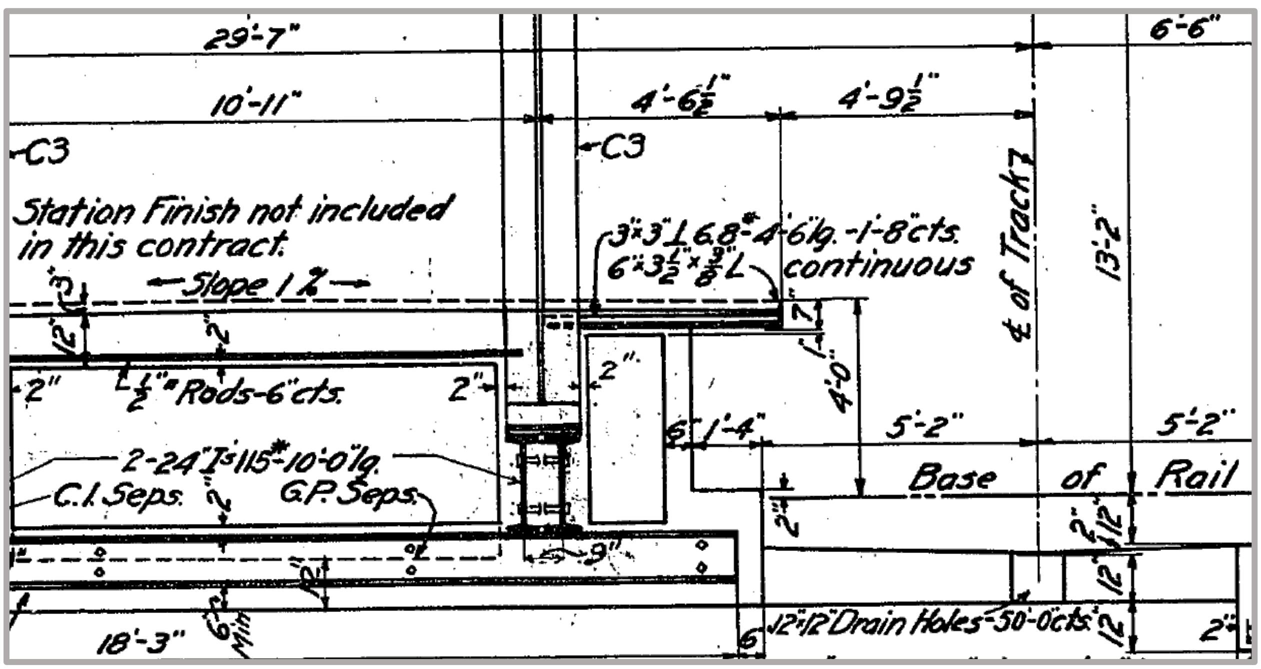

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

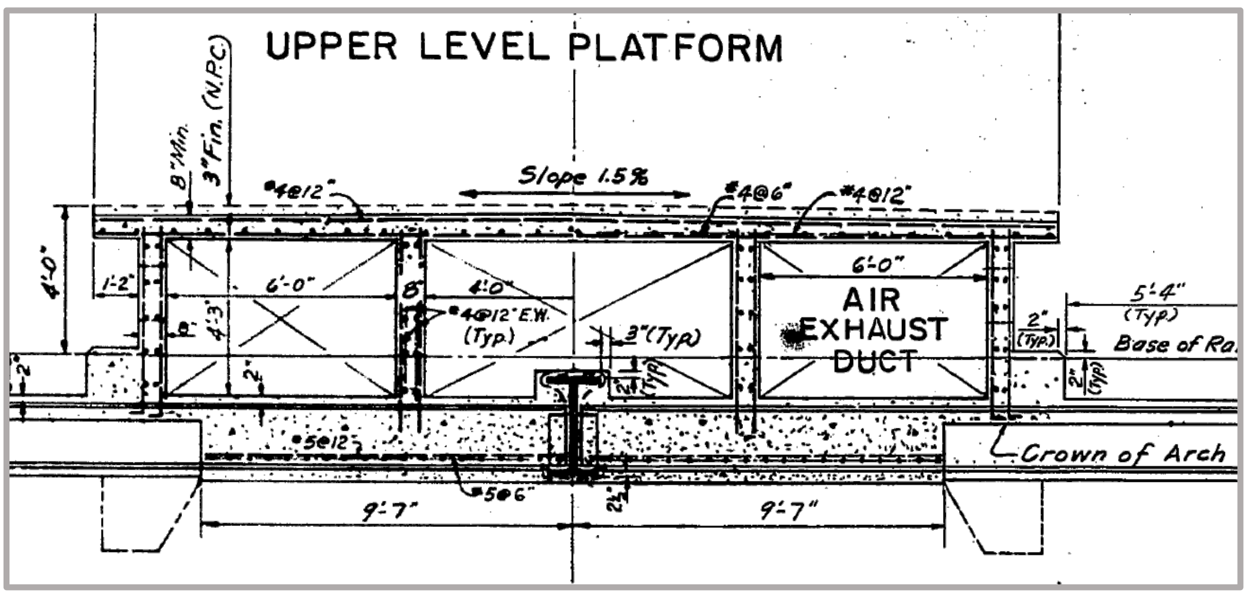

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

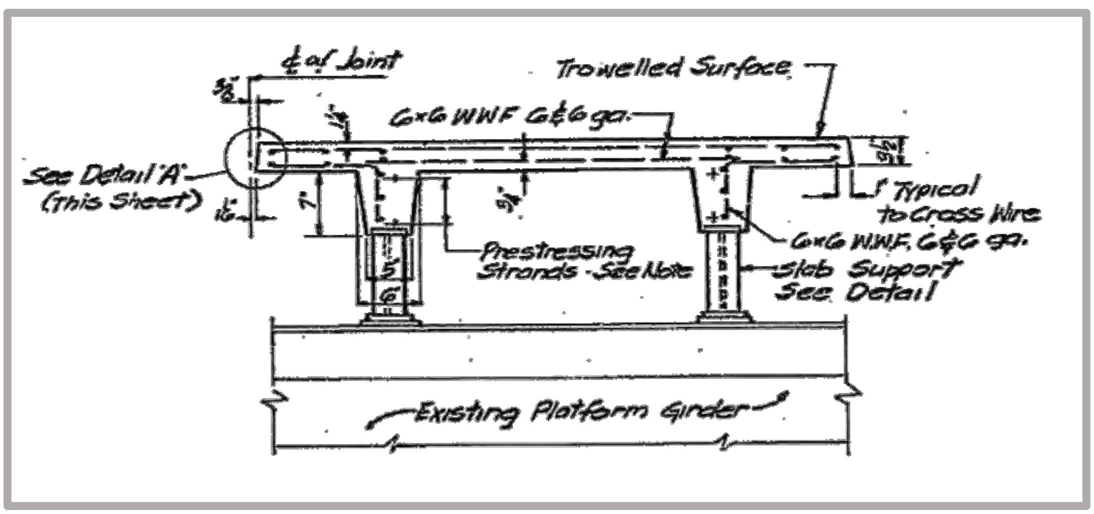

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

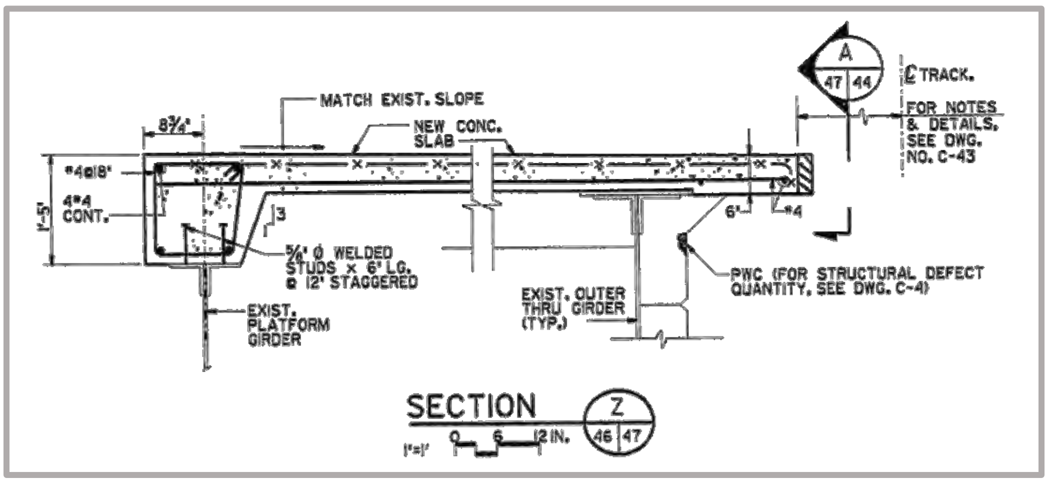

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2’-9”), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

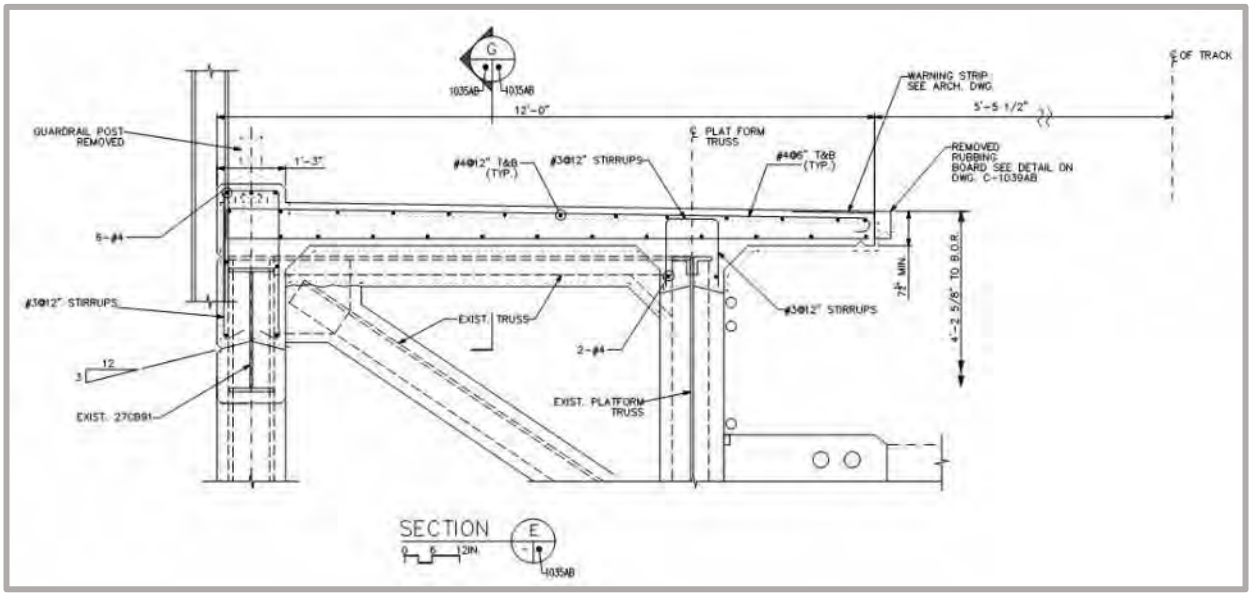

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

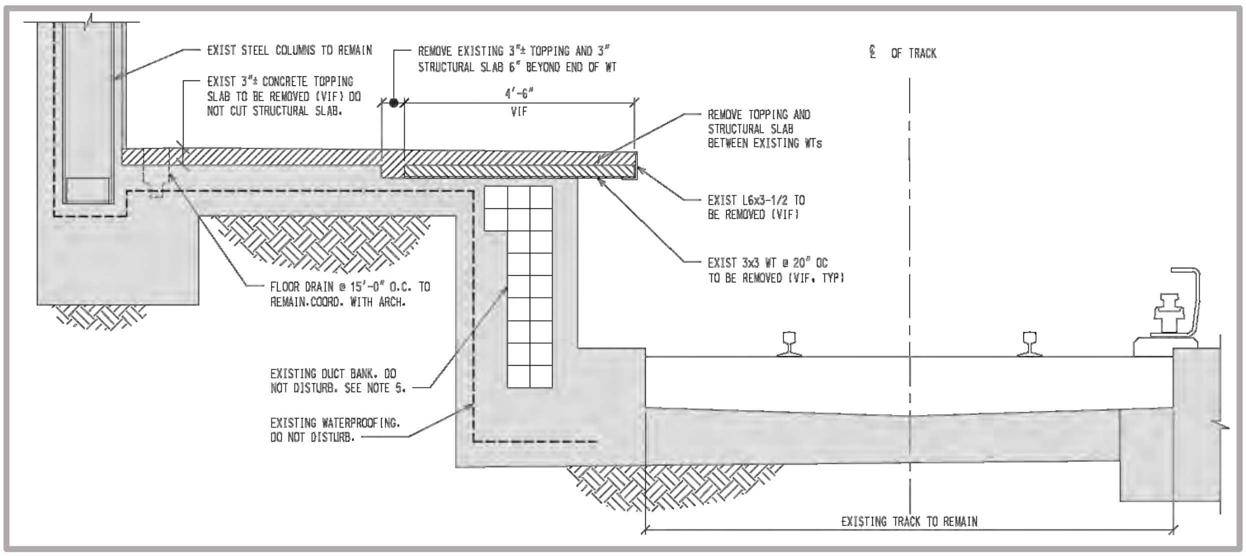

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

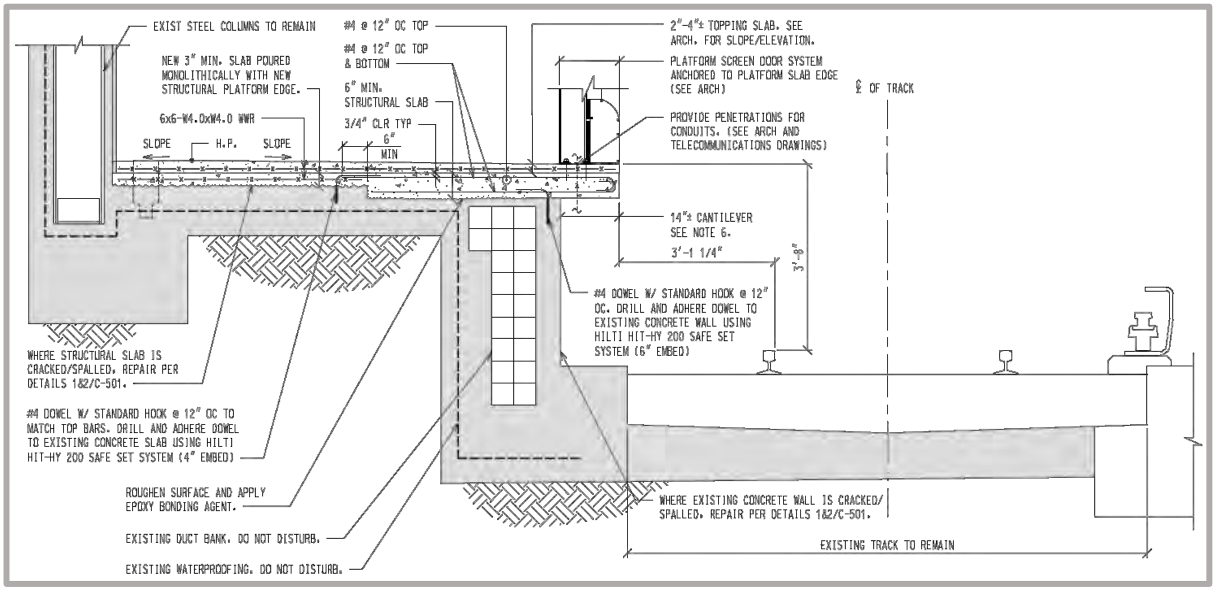

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

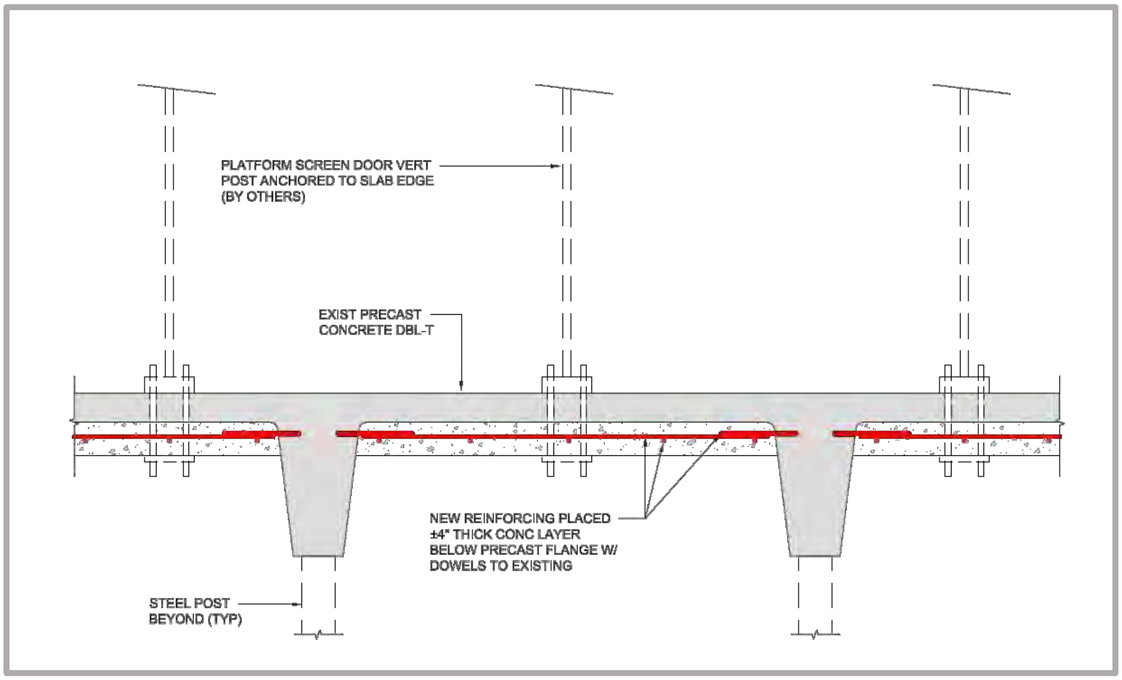

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for M - Line Stations

MTA/NYCT

October 29, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 31 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 8 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for M - Line Stations

MTA/NYCT

October 29, 2018

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	525	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	525	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,050**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**8**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,050	LF	7	7,351
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,251	SF	12	63,006
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	106	CY	2,500	265,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,052	EA	25	26,303
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,052	EA	25	26,303

Tier 2-3 Report on Feasibility of Platform Edge Barriers for M - Line Stations

29-Oct-18

STATION : FOREST AVENUE 67TH AVE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,053	LF	60	63,204
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Rooms from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	8	EA	16,000	128,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	8	EA	15,000	120,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	192	EA	4,629	888,814
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	192	EA	5,566	1,068,588
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for M - Line Stations

29-Oct-18

STATION : MYRTLE / WYCKOFF AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	556	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	556	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,112**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**8**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,112	LF	7	7,783
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,559	SF	12	66,708
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	112	CY	2,500	280,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,114	EA	25	27,845
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,114	EA	25	27,845
19	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
20	Polyethylene edge strip	1,112	LF	95	105,621
21	Provide sleeves for HV & LV wires	264	EA	110	29,040
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,112	LF	15	16,677
26	Remove existing platform tiles	1,112	LF	12	13,342
27	Sawcut existing topping concrete at perimeter of removal area	1,112	LF	5	5,559
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,671	SF	8	53,366
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,112	SF	15	16,677

MTA New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘G’ LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

SUBMITTAL DATE: December, 26 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 21 newly evaluated stations, 15 have been found to be not suitable for the installation of PSDs.

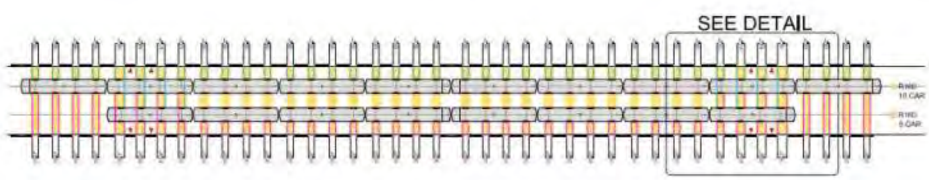
[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the G line service and an overlapping service on the B Division will remain incompatible even after 2032. Per discussions with Operations Planning, (see Appendix F) future trains will consist of eight 60-foot cars, whereas the F line is a ten-car train. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The G train ridership does not warrant a ten-car train, so this incompatibility will likely remain into the foreseeable future. Therefore, 8 of the 21 stations are infeasible due to this incompatibility. Please see the diagrams in Figure 1 below.



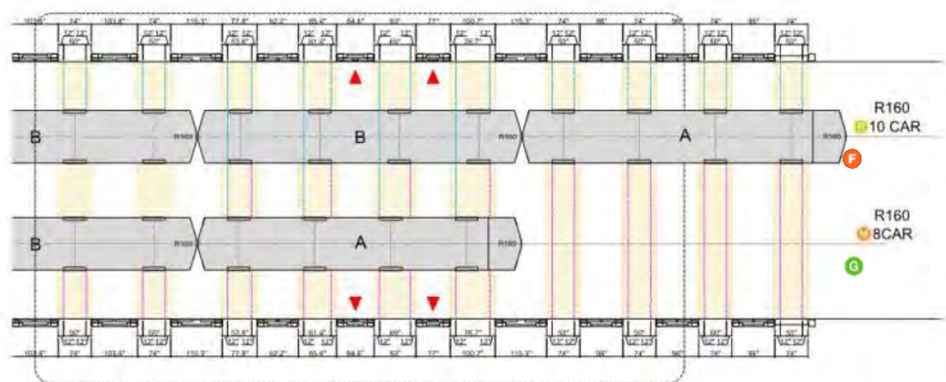


***Figure 1** – Ten-car vs. eight-car train*
Comparison of door geometry

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at 13 of the stations on the 'G' Line. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 29% of the 'G' Line stations. Total implementation cost would be $183.4M for APGs and $239.6M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 6 feasible stations, the aggregate annual maintenance cost would be $5.6M.

Summary Table

G Line Summary of Feasibility					(29% feasible; 6/21)

					TOTAL	**183.4M**	**239.6M**

1.0 Station Assessments

1.01 – MRN 175 | Hoyt Schermerhorn Streets

Summary: *Hoyt Schermerhorn Streets Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see Figure 1). This condition occurs at multiple stairs both station platforms.*

Description

Hoyt Schermerhorn Streets Station is a below-grade station with four platforms, two open revenue platforms in the center and two abandoned platforms on the sides. The revenue platforms are in island configuration, they are straight and have slight curves at their southern ends. The platform structures are cast-in-place concrete. The width of the platforms is approximately 20'-6" throughout tapering down to 16'-10" at the southern end of the station. There are three staircases along each revenue platform, all of which would not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. These staircases are centered on the platform and flanked on both sides by the typical station columns, where the column face is 3'-4" away from adjacent platform edge. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. As seen in Figure 1, the implementation of a platform edge barrier would reduce this width below the required minimum of 32" for pinch-points, the remaining 25" would not allow for ADA compliant wheelchair movement.

Figure 1: *Non-Compliant ADA condition at stairs (typical on all platforms)*
MRN 175: Hoyt Schermerhorn Streets Station

1.02 – MRN 281 | Court Square Station

Summary: *Court Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at all 4 staircases on the platform (See Figure 1). Wheelchair paths at the aforementioned locations would be constricted to less than 32".*

Description

Court Square Station is a below-grade station with one straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 19'-6" throughout. There are four staircases along the platform and two rooms, all of which would not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-5" away from all platform edges. The stairs are not centered on the platform but shifted towards the southbound track edge. All stairs are flanked on both side by the aforementioned typical station columns. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-5" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32" for pinch-points. The remaining 26" would not allow for ADA compliant wheelchair movement. Please see Figure 1 for reference

***Figure 1** – Non-Compliant ADA condition*
MRN 281: Court Square

1.03 – MRN 282 | 21st Street Van Alst Jackson Avenue

Summary: *21st Street Van Alst Jackson Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at both staircases on the platform. Wheelchair paths at the staircase locations would be constricted to less than 32".*

Description

21st Street Van Alst Jackson Avenue is a below-grade station with one straight center/island platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 19'-4" throughout. There are two open staircases along the platform (and one closed staircase at the south end), both of which would not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-5" away from all platform edges. The stairs are centered on the platform. The stair are flanked on both sides by the typical station columns. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-5" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32" for pinch-points. The remaining 26" would not allow for ADA compliant wheelchair movement. Please see Figure 1 for reference

Figure 1 *– Non-Compliant ADA condition at staircase P5*
MRN 282: 21st Street Van Alst Jackson A

1.04 – MRN 283 | Greenpoint Avenue Station

Summary: *Greenpoint Avenue Station is feasible for both APGs and PSDs. There is a continuous standpipe running through multiple locations of the platform edges (see Figure 3). This standpipe would likely need to be relocated in the implementation of a full height PSD system. There are also two ceiling mounted monitors located above the southbound platform edge with a vertical clearance of 6'8", which would also require relocation. Platform edge reconstruction will be required to support the requirements of an APG (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Greenpoint Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-2" from the platform edge. The southbound platform width is approximately 11'-6" throughout. The northbound platform width is approximately 11'-8" throughout. On the southbound platform there are two ceiling mounted monitors located above the platform edge, with a vertical clearance of 6'-8", (see Figure 3). Ceiling heights measure no less than 7'-6" throughout. Please see Figure 1 for overall station plan and Figure 2 for an enlarged room location.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station. Ceiling mounted monitors located above the platform edge would need to be relocated in the implementation of full height PSDs (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the southeast of the mezzanine, flush to the wall as seen in Figure 2. The proposed room dimension is 27'-0" x 11'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 1. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

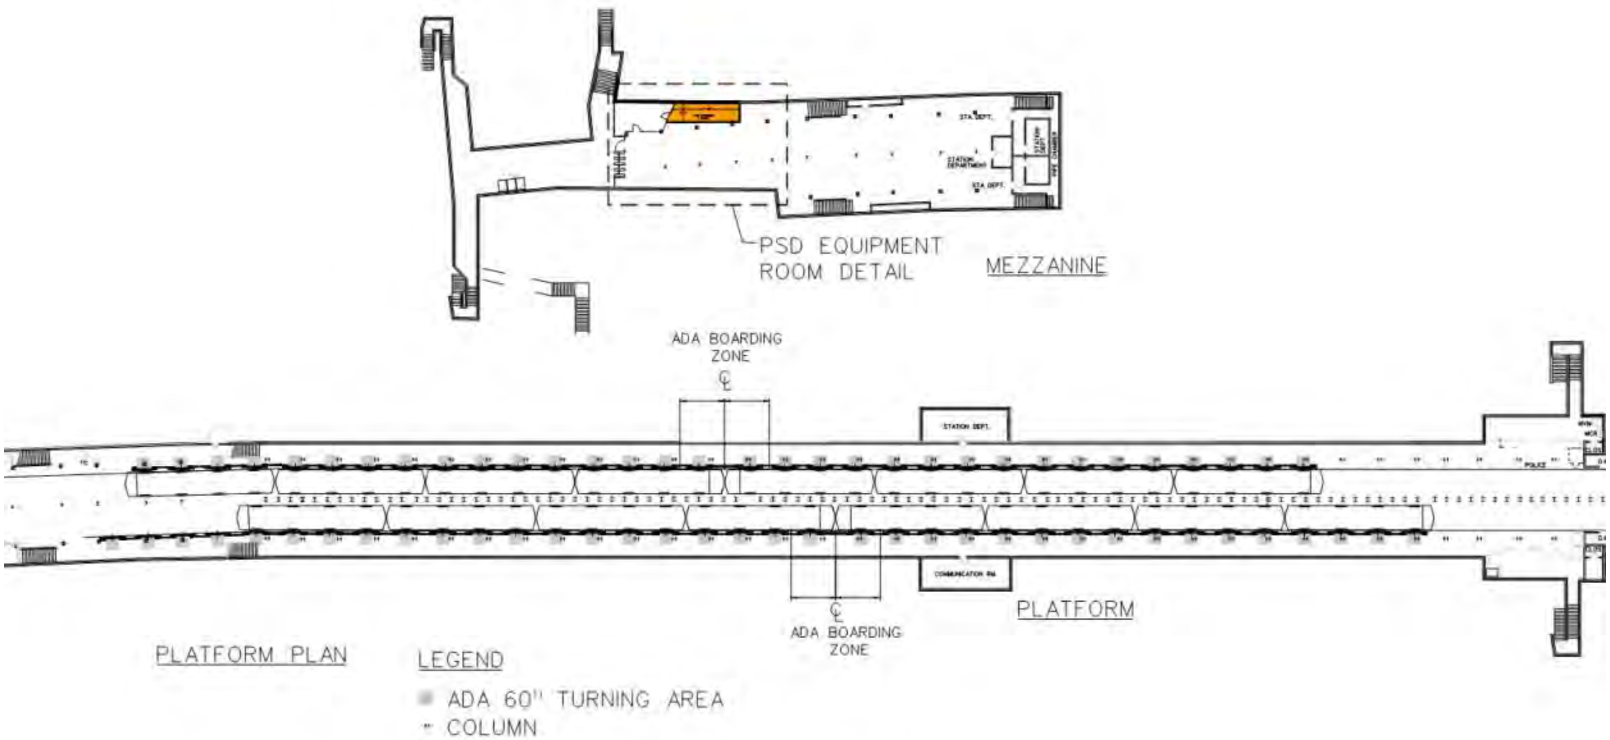

***Figure 1** – Station Plan*
MRN 283: Greenpoint Avenue
Note: Since currently the 'G' line runs a 4 car consist, accurate measurements could not be obtained for train stopping locations. As such the train locations shown on this report are approximated to center each 8 car consist on its respective platform

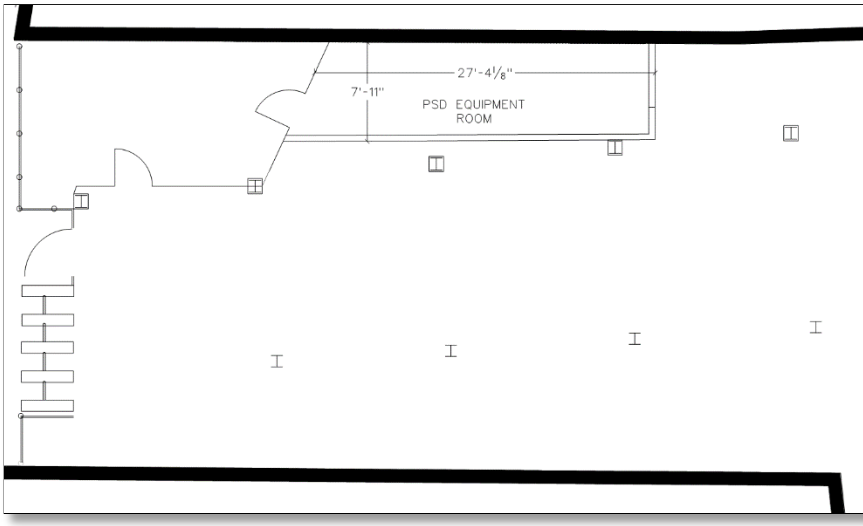

***Figure 2** – PSD Equipment Room Detail*
MRN 283: Greenpoint Avenue

Platform obstructions within 5' of edge:

Southbound Track:

- Columns
- Freestanding monitors

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:
Existing electrical service has adequate capacity to support the implementation of a APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Greenpoint Ave Manhattan Ave.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	74.4
Apparent Power (kVA)	93.0
Station Peak Demand Load, Max Current, (A)	258.3
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	423
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	377
Is Electrical Service Adequate?	**YES**
Notes	Service rating is based on the Field survey: 800 Amps (Fuse & Feeder)

Table 1 *–Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.4M to install APGs and $39.9M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with standpipe*
MRN 283 – Greenpoint Avenue

1.05 – MRN 284 | Nassau Avenue Station

Summary: *Nassau Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction will be required to support the requirements of an APG (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Nassau Avenue Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Back-of-house elements are located throughout the platform level either in non-public rooms or at the platform ends away from the circulation paths. Columns are spaced 15’-0” on center with column faces approximately 3’-5” from the platform edge. Typically, the platform widths are approximately 11’-8”. Ceiling heights measure no less than 7’-6” throughout. Please see Figure 1 for overall station plan, Figure 2 for an enlarged room location and Figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the Southbound Platform (To Brooklyn) adjacent to Control Area N406. The proposed room dimension is 27’-0” x 7’-0” (see Figure 1 & Figure 2 for reference)

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

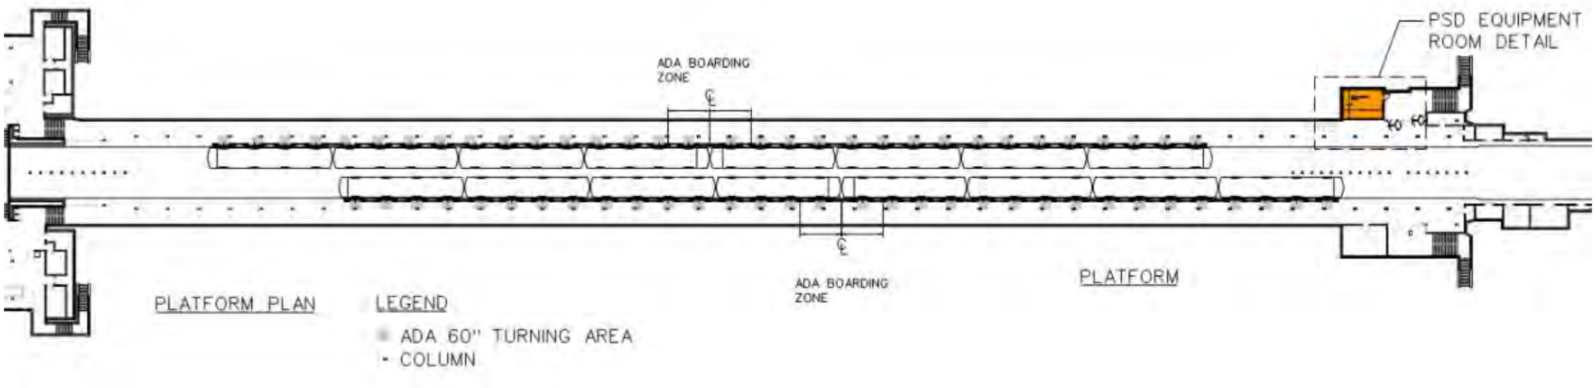

Figure 1 *– Station Plan*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.8M to install APGs and $41.1M to install PSDs (See Appendix E)

Figure 3 *– Typical platform view*
MRN 284: Nassau Avenue

1.06 – MRN 285 | Metropolitan Avenue

Summary: *Metropolitan Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch-point width requirement for ADA complaint wheelchair movement would not be met at the platform edge adjacent the southernmost staircase on both platforms as the remaining width would be 27" (see Figure 1).*

Description

Metropolitan Avenue Station is a below-grade station with two side platforms. The platform structures are cast-in-place concrete. The width of both platforms is approximately 11'-4" throughout. There are three staircases along each platform. Columns are typically spaced 15' on center with column faces typically 3'-6" away from all platform edges. Passengers requiring an ADA-compliant path of travel can currently move along any area on both platforms. The implementation of a platform edge barrier would reduce existing widths below the required minimum of 32" for pinch-points at the platform edge adjacent to the southernmost staircase on both platforms. Currently the columns adjacent to the southernmost staircases are 42" measured column face to platform edge. If a PSD System is implemented the remaining 27" would not allow for ADA compliant wheelchair movement. Please see Figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition at the platform edge adjacent to southernmost staircase on the southbound platform MRN 285: Metropolitan Avenue*

1.07 – MRN 286 | Broadway Union Avenue

Summary: Broadway Union Avenue station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch-point width requirement for ADA complaint wheelchair movement would not be met at platform edges adjacent to all staircases as the remaining width would be 23" (see Figure 1).

Description

Broadway Union Avenue Station is a below-grade station with two side platforms. The platform structures are cast-in-place concrete. The width of both platforms is approximately 11'-2" throughout. There are two staircases along each platform. Columns are typically spaced 15' on center with column faces typically 3'-2" away from all platform edges. Passengers requiring an ADA-compliant path of travel can currently utilize the corridor between the platform edge and the column faces. The implementation of a platform edge barrier would reduce existing widths below the required minimum of 32" for pinch-points at the platform edges adjacent to all platform level staircases. Currently the staircases are flanked by typical columns on the side adjacent to the platform edge. If a PSD System is implemented the remaining 23" would not allow for ADA compliant wheelchair movement. Please see Figure 1 for reference.

***Figure 1** – Non-Compliant ADA condition at the platform edge adjacent to staircase P3 on the southbound platform MRN 286: Broadway Union Avenue*

1.08 – MRN 287 | Flushing Avenue Station

Summary: *Flushing Avenue is feasible for both APGs and PSDs. Platform edge reconstruction will be required to support the requirements of an APG or PSD system (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Flushing Avenue Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-4" from the platform edge. The platform widths vary from approximately 11'-8" to 17'8". Ceiling heights measure no less than 7'-6" throughout. Please see Figure 1 for overall station plan, Figure 2 for an enlarged room location and Figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the Northbound-bound platform adjacent to the Control Area N414. The proposed room dimension is 27'-0" x 7'-0" (see Figure 1 & Figure 2 for reference)

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Platform edge reconstruction would be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

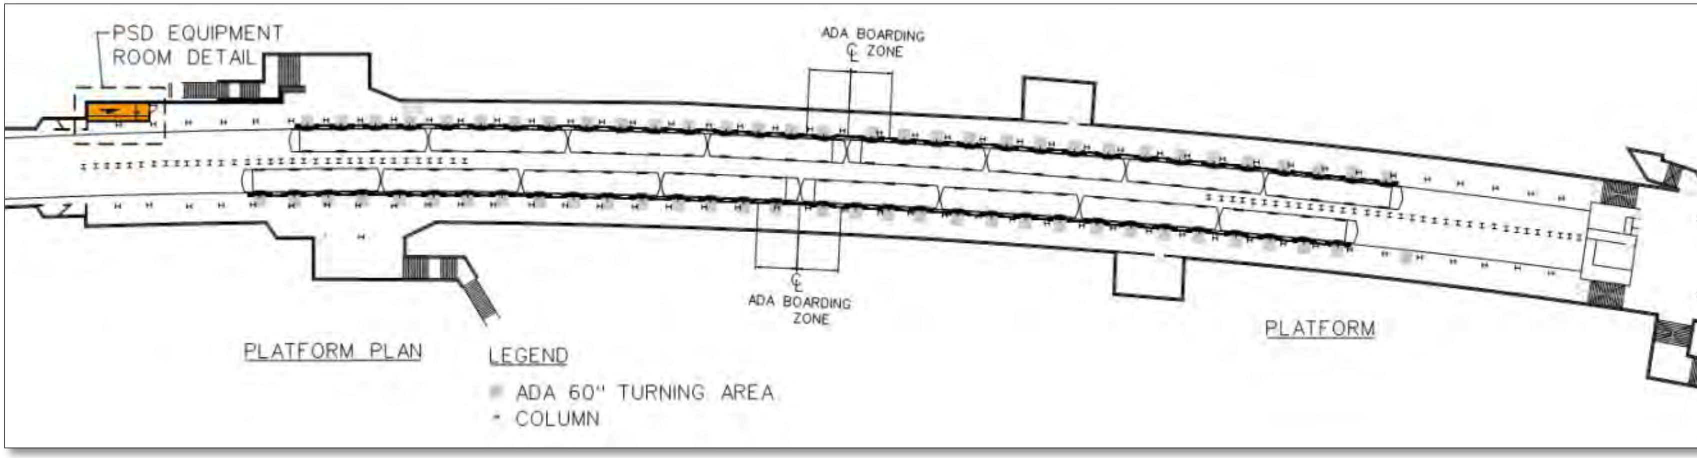

***Figure 1** – Station Plan*
MRN 287: Flushing Avenue Station

Note: Since currently the 'G' line runs a 4 car consist, accurate measurements could not be obtained for train stopping locations. As such the train locations shown on this report are approximated to center each 8-car consist on its respective platform

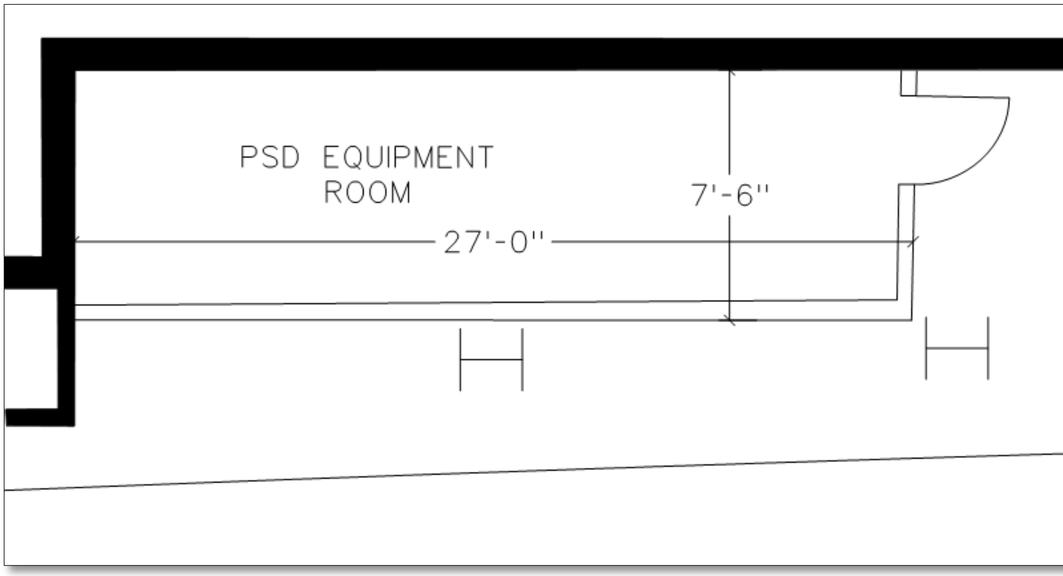

Figure 2 – *PSD Equipment Room Detail*
MRN 287: Flushing Avenue Station

Platform obstructions within 5' of edge:

Southbound Track (To Brooklyn):

- Columns
- Freestanding Monitor

Northbound Track (To Queens):

- Columns

These obstructions do not present an impediment to the installation of PSDs

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Existing electrical service has adequate capacity to support the implementation of a APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Flushing Avenue Marcy Ave.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	55.2
Apparent Power (kVA)	69.0
Station Peak Demand Load, Max Current, (A)	191.7
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	357
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	443
Is Electrical Service Adequate?	**YES**
Notes	Service rating is based on the Field survey: 800 Amps (Fuse & Feeder)

***Table 1** – Power Capacity Analysis*

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.6M to install APGs and $39.3M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with MRN 287 – Flushing Avenue Station*

1.09 – MRN 288 | Myrtle Willoughby Street Station

Summary: *Myrtle Willoughby Street station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at the all underpass stairs (see figure 1).*

Description

Myrtle Willoughby Streets Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. The width of both platforms varies from 13'-4" to 17-'4" throughout. There are four staircases along each platform, two of which lead to the underpass and do not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-4" away from all platform edges. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. The implementation of a platform edge barrier would reduce this width at the underpass stairs below the required minimum of 32 for pinch-points". The remaining 25" would not allow for ADA compliant wheelchair movement. Please see Figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition at the platform edge adjacent to the underpass stairs*
MRN 288: Myrtle Willoughby Streets Station

1.10 – MRN 289 | Bedford Nostrand Avenue Station

Summary: *Bedford Nostrand Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 33" (see figure 1). This condition occurs at all stairs on both sides of each platform throughout the station.*

Description

Bedford Nostrand Avenue station is a below-grade station with two straight center/island platforms. The platform structure is cast-in-place concrete. The width of both platforms is approximately 13'-8" throughout. There are six staircases along each platform, all of which would not allow for the 36" width required for wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 6'-4" away from all both platform edges. The stairs are centered on the platform. Staircases are not flanked by typical station columns, rather the columns are situated along the platform centerline, in line with the staircases. The staircases are 4' away from both platform edges. Passengers requiring an ADA-compliant path of travel can currently move anywhere along the platform. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 33" would not allow for ADA compliant wheelchair movement.

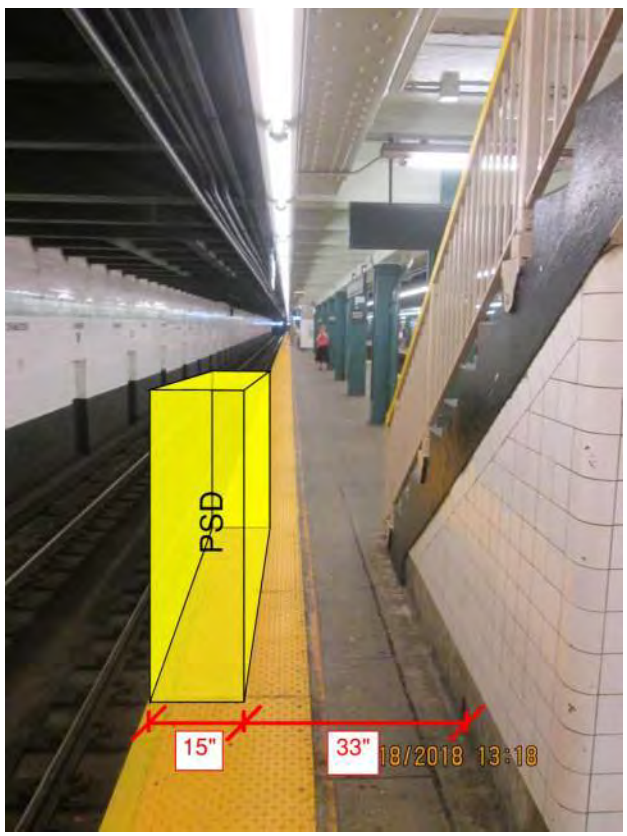

Figure 1 *– Non-Compliant ADA condition at the platform edge by a staircase*
MRN 289: Bedford Nostrand Avenue Station

1.11 – MRN 290 | Classon Avenue Station

Summary: *Classon Avenue is feasible for both APGs and PSDs. There is a continuous standpipe running through multiple locations of the southbound platform edge (see Figure 3). This standpipe would likely need to be relocated in the implementation of a full height PSD system. Platform edge reconstruction will be required to support the requirements of an APG (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Classon Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Columns are spaced 15’-0” on center with column faces approximately 3’-4” from the platform edge. Typically, the platform widths are approximately 11’-4”. On the southbound platform there is a continuous standpipe running through multiple locations of the platform edges. This standpipe would likely need to be relocated in the implementation of a full height PSD system. Ceiling heights measure no less than 7’-6” throughout. Please see Figure 1 for overall station plan, Figure 2 for enlarged room location and Figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station. Present Standpipe on southbound platform would need to be relocated in the implementation of full height PSDs (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the east side of the mezzanine level adjacent to staircase P4. The proposed room dimension is 27’-0” x 7’-6” (see figure 1 & figure 2)

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

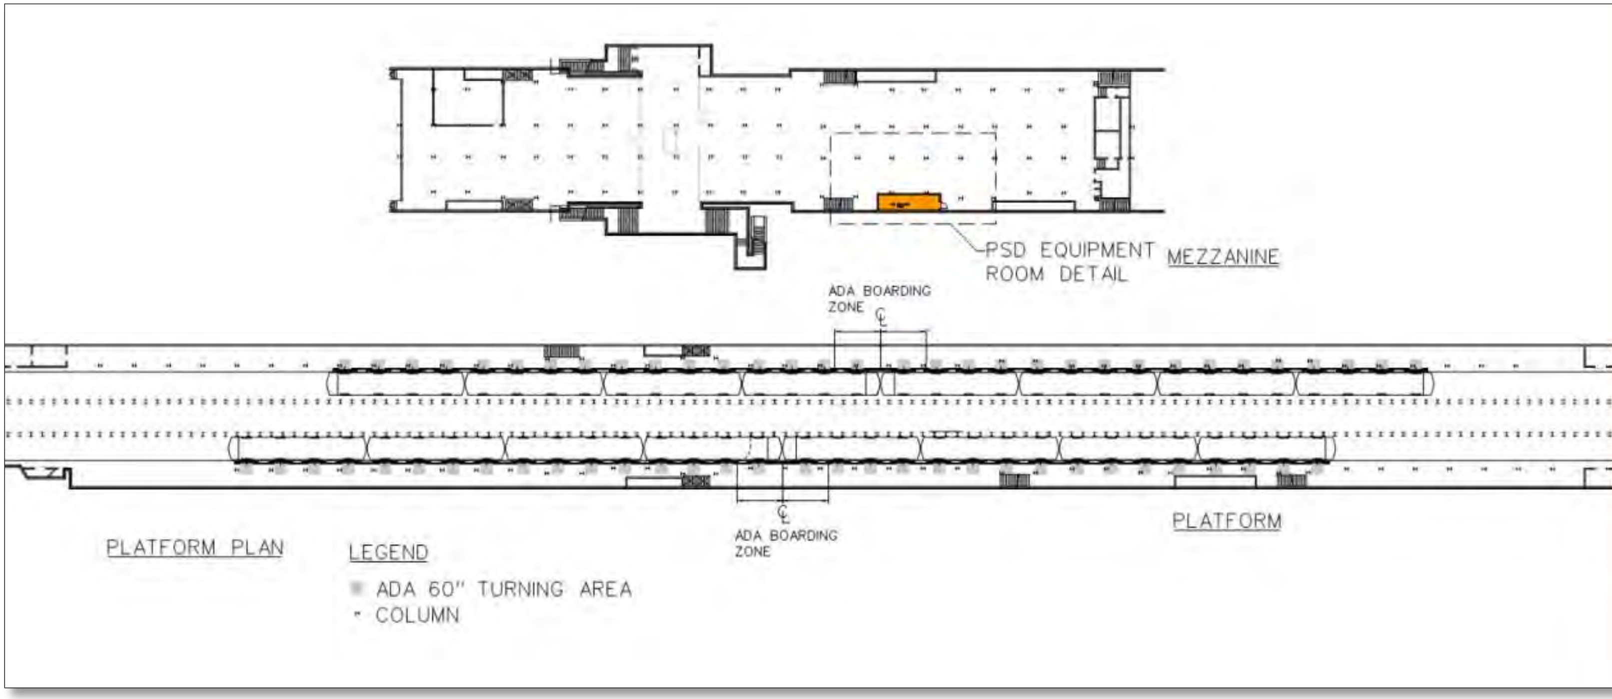

Figure 1 *– Station Plan*
MRN 290: Classon Avenue

Note: Since the 'G' line currently runs a 4 car consist, accurate measurements could not be obtained for train stopping locations. As such the train locations shown on this report are approximated to center each 8-car consist on its respective platform

The total cost for this station is estimated to be $30.5M to install APGs and $39.4M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with standpipe*
MRN 290 – Classon Avenue Station

1.12 – MRN 291 | Clinton & Washington Avenues Station

Summary: *Clinton & Washington Avenues Station is feasible for both APGs and PSDs. There is a continuous standpipe running through multiple locations of the platform edges (see Figure 3). This standpipe would likely need to be relocated in the implementation of a full height PSD system. Platform edge reconstruction will be required to support the requirements of an APG (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Clinton & Washington Avenues Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-4" from the platform edge. Typically, the platform widths are approximately 11'-4". On both platforms there is a continuous standpipe running through multiple locations of the platform edges. This standpipe would likely need to be relocated in the implementation of a full height PSD system. Ceiling heights vary throughout the station, ranging from 7-0" to 7'-6". Please see Figure 1 for overall station plan, Figure 2 for enlarged room location and Figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station. Present Standpipe on both platforms would need to be relocated in the implementation of full height PSDs (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the east side of the mezzanine level adjacent to staircase P7. The proposed room dimension is 27'-6" x 7'-0" (see figure 1 &* figure 2)

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. ***Figure 3** – Typical platform view with standpipe & free-standing monitor*
MRN 291 – Clinton & Washington Avenues

1.13 – MRN 292 | Fulton Street Lafayette Avenue Station

Summary: *Fulton Street Lafayette Avenue is feasible for both APGs and PSDs. There is a continuous standpipe running through multiple locations of both platform edges (see Figure 3). This standpipe would likely need to be relocated in the implementation of a full height PSD system. On the northbound platform edge there are is also a ceiling mounted monitor located above the platform edge with a vertical clearance of 6'-8" and a signal light located above the platform edge with a vertical clearance of 7'-8" both of which would also require relocation. Platform edge reconstruction will be required to support the requirements of an APG or PSD system (see structural report; Appendix B). Electrical capacity at this station is adequate to support a APG/PSD system*

Description

Fulton Street Lafayette Avenue Station is a below-grade station with two straight side platforms. The platform structure is cast-in-place concrete. Columns are spaced 15'-0" on center with column faces typically 3'-4" from the platform edge. The platform widths vary from approximately 5'-6" to 20' 10". There is a continuous standpipe running through multiple locations of both platform edges (see Figure 3). This standpipe would likely need to be relocated in the implementation of a full height PSD system. On the northbound platform edge there are is also a ceiling mounted monitor located above the platform edge with a vertical clearance of 6'-8" and a signal light located above the platform edge with a vertical clearance of 7'-8" both of which would also require relocation. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station. Existing standpipe, ceiling mounted monitors & signals lights would need to be relocated in the implementation of full height PSDs (see figure 3)

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the northbound platform adjacent to the Transfer Closet. The proposed room dimension is 27'-0" x 7'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Platform edge reconstruction would be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.25 On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

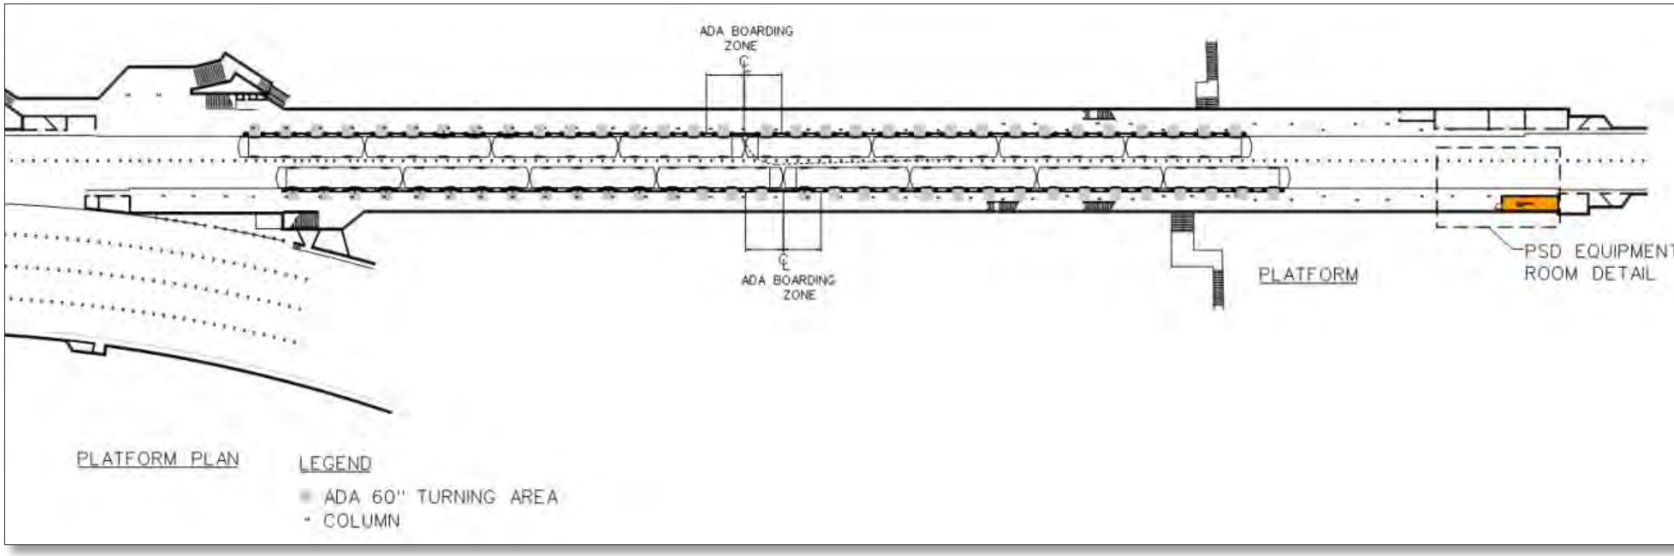

Figure 1 *– Station Plan*

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for <u>Tier 2 Stations'</u> screening will include the following:*
>
> - *a. Column location in relation to the platform edge*
> - *b. Platform edge clearance adjacent to stairs and other impediments*
> - *c. Impacts to ADA path of travel and boarding areas*
> - *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> - *e. Sufficient platform width*
> - *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for <u>Tier 3 Stations</u> will include the following:*
>
> - *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> - *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> - *c. Confirmation of adequate power for PSD/APG/RPSDs*
> - *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> - *e. Determination of communications requirements, availability and cost*
> - *f. Determination of gap detection and entrapment avoidance technology requirements*
> - *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

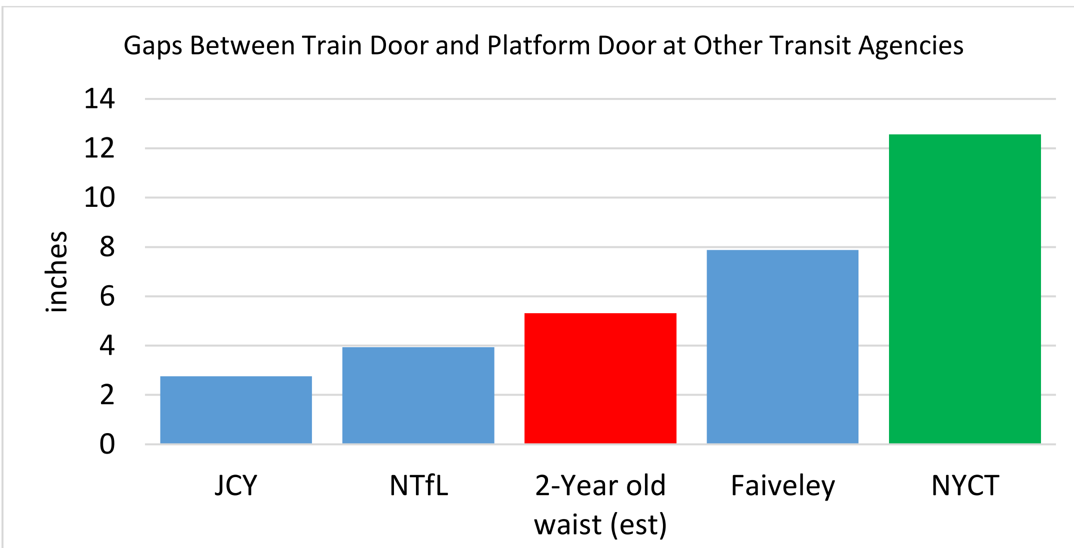

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

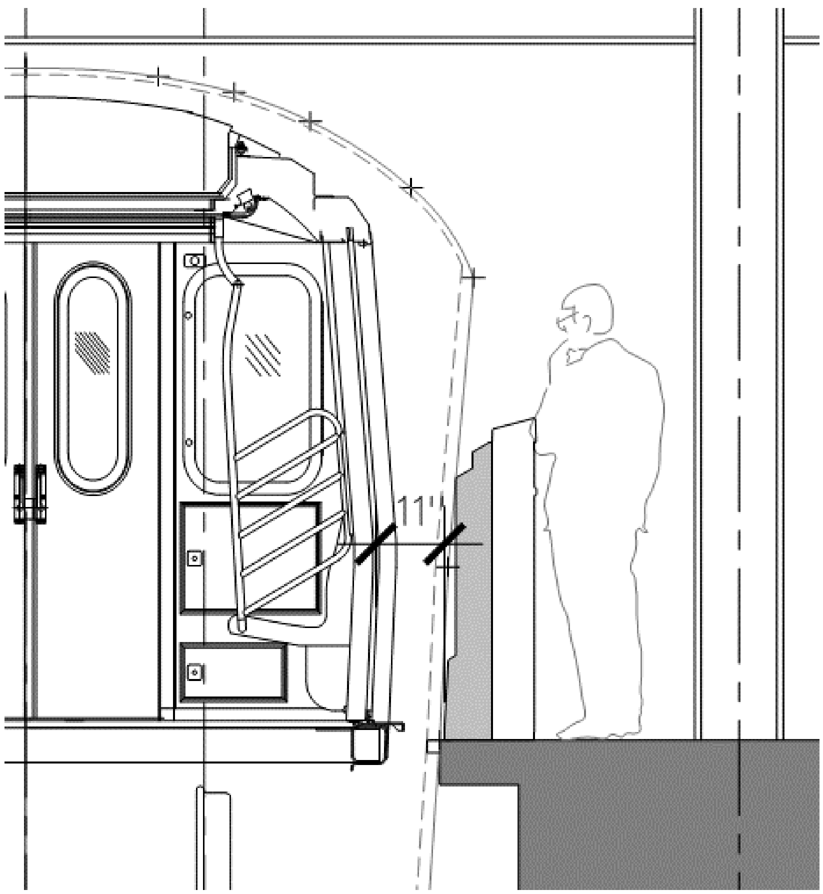

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

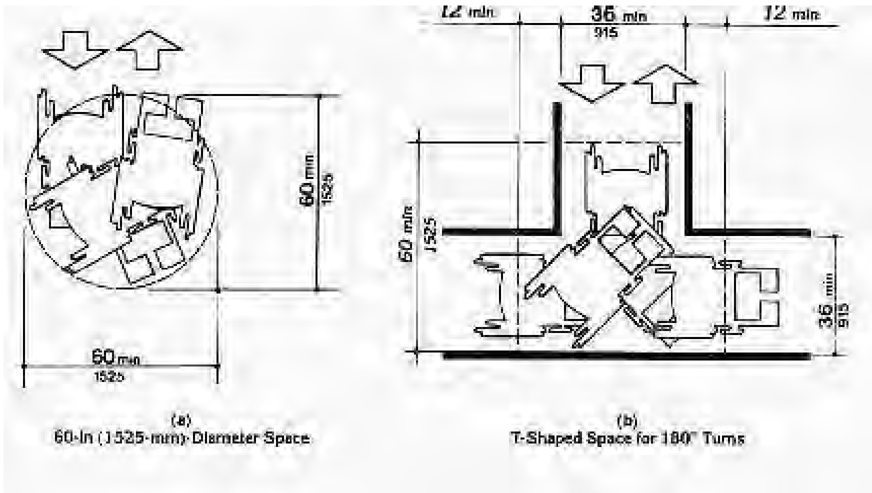
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

> *Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.*

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

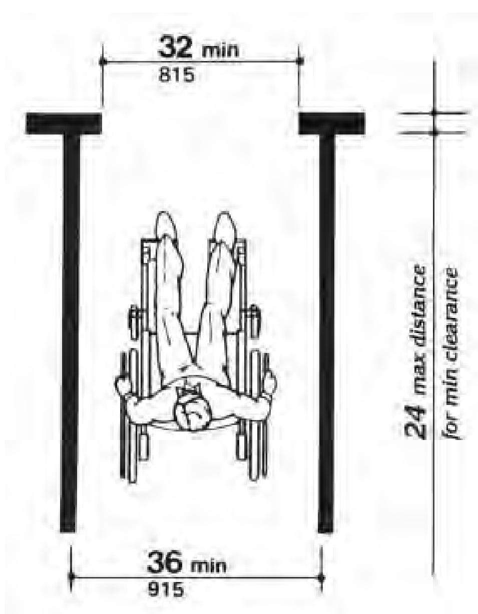


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as “existing”; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60” turning radius in which to make this turn. (the “T” shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an “alteration to the path of travel”, requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32” point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

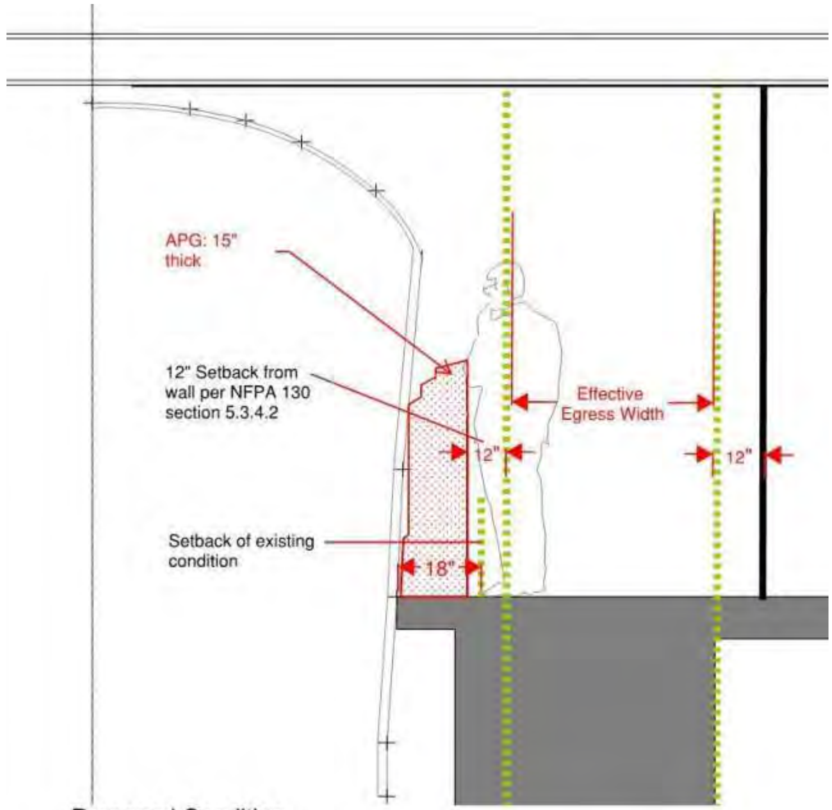
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

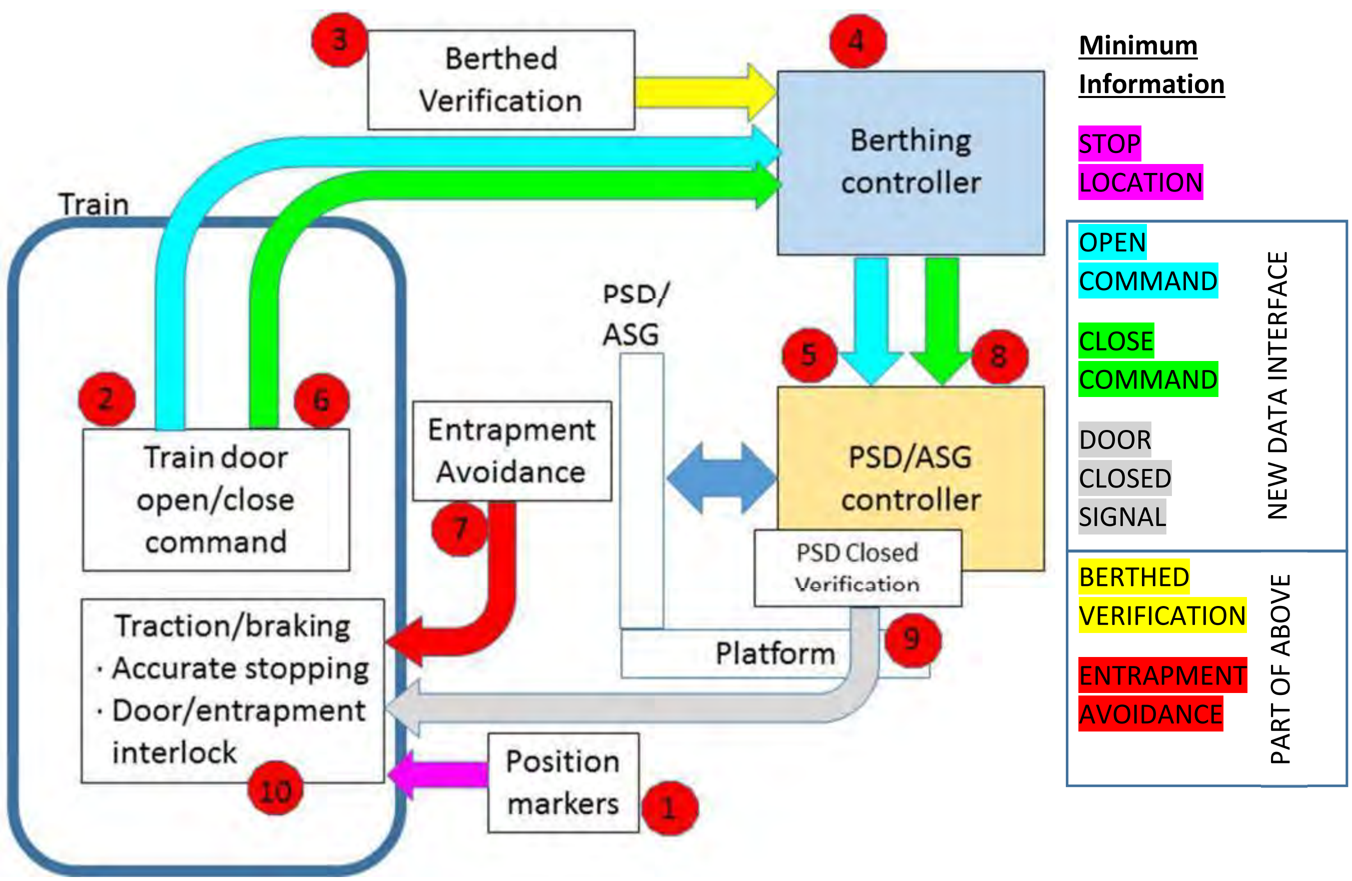
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

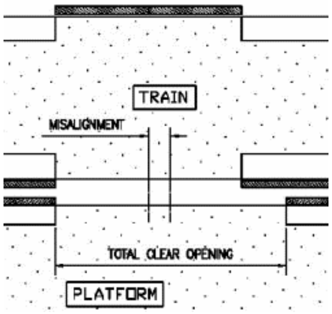
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

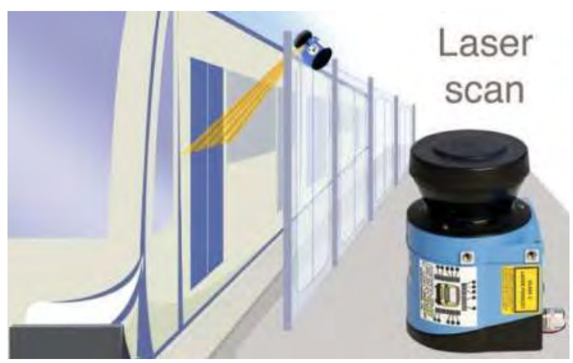
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

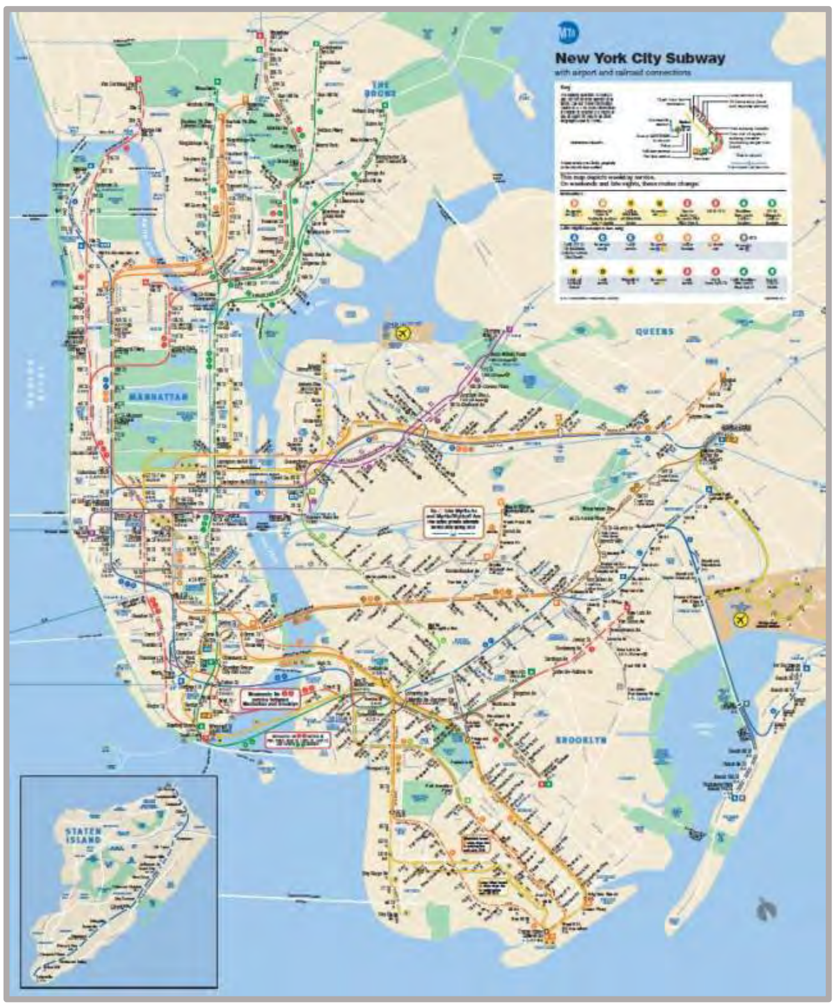


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

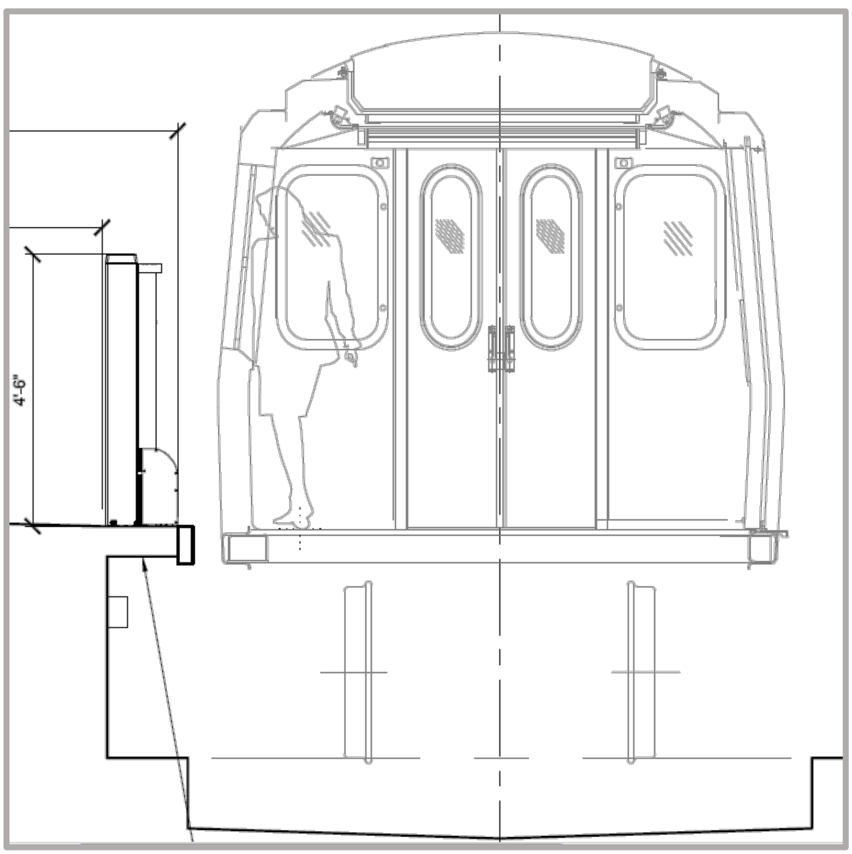

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

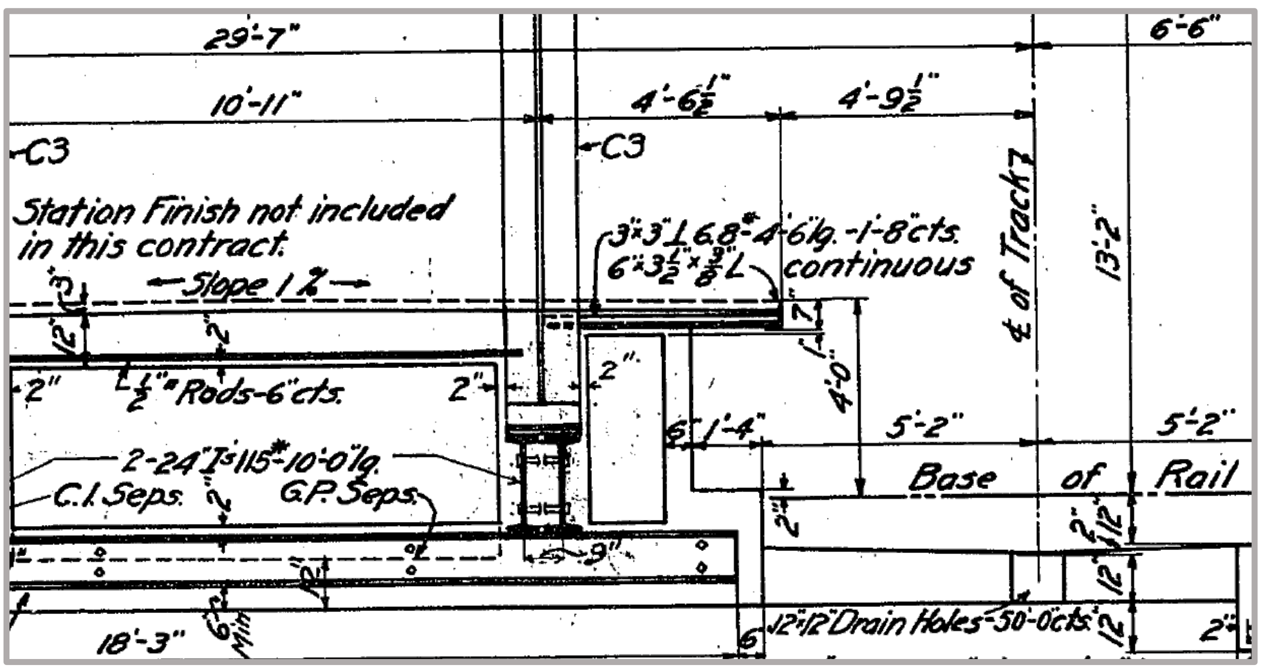

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

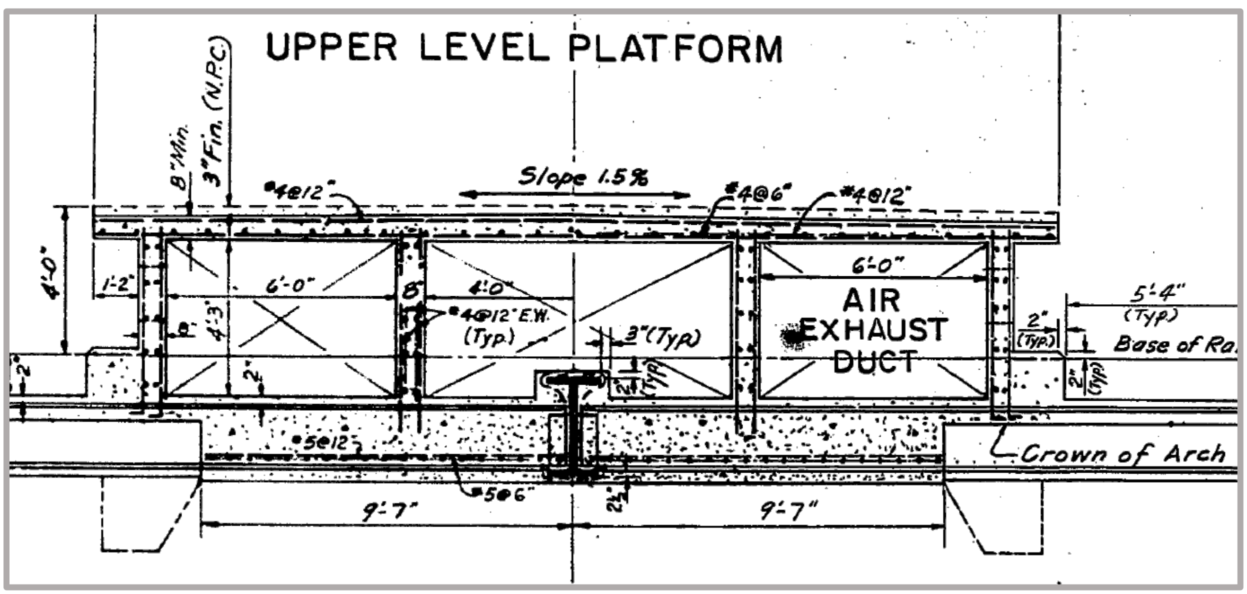

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

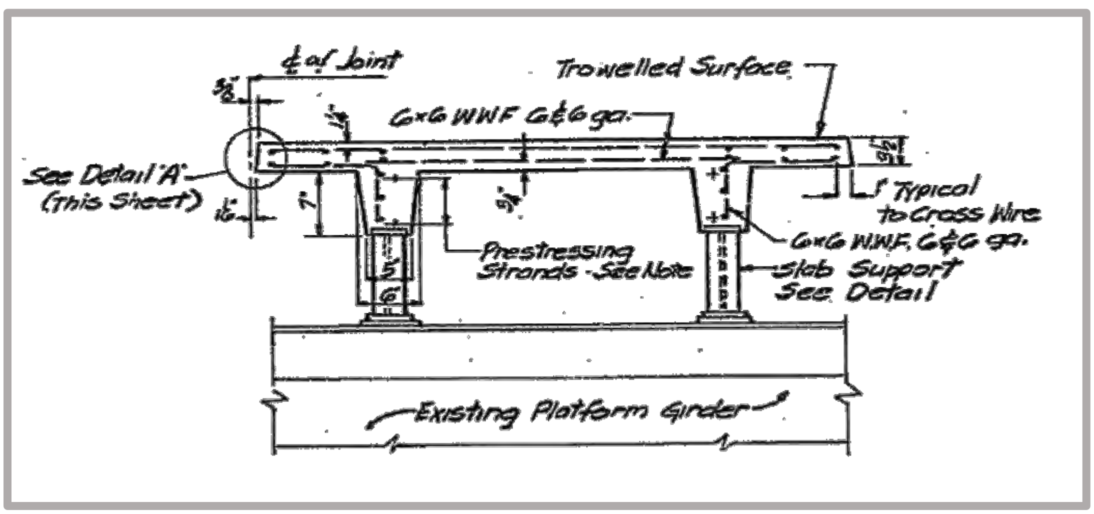

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

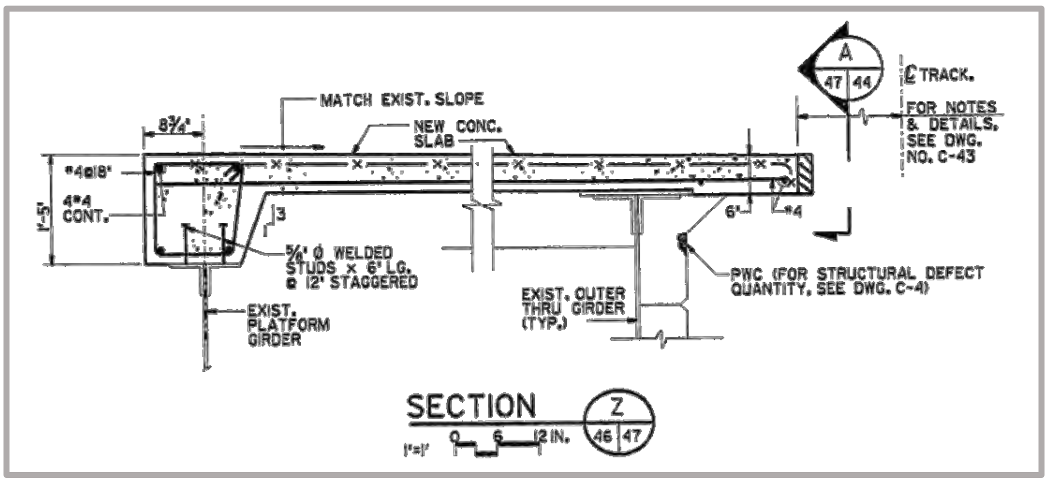

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2’-9”), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

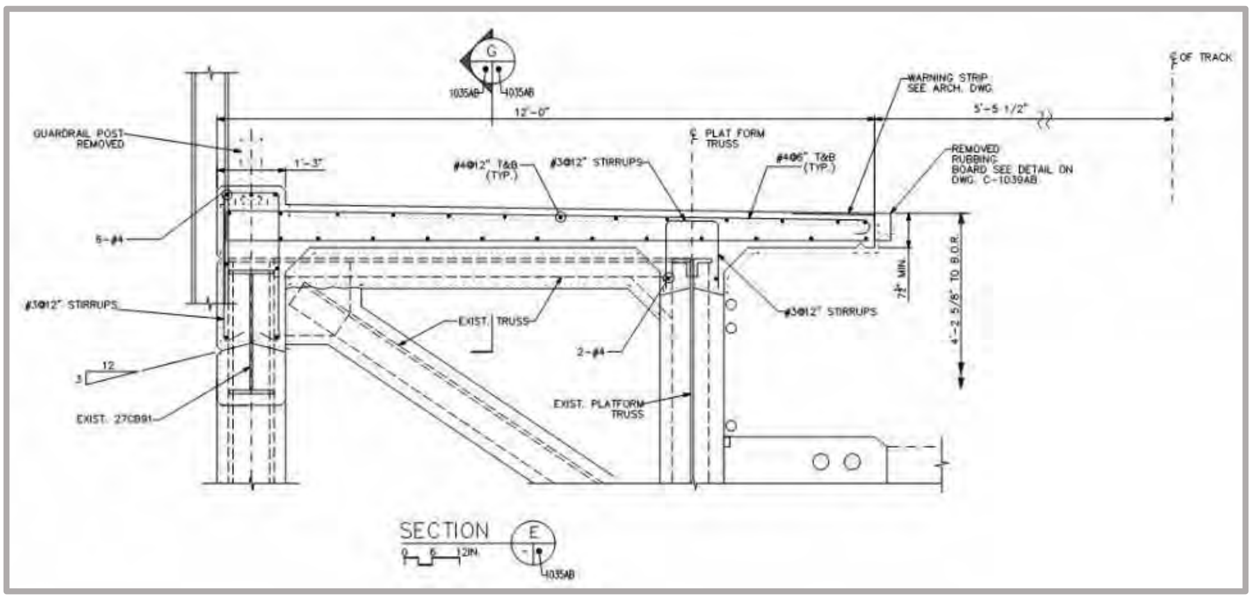

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

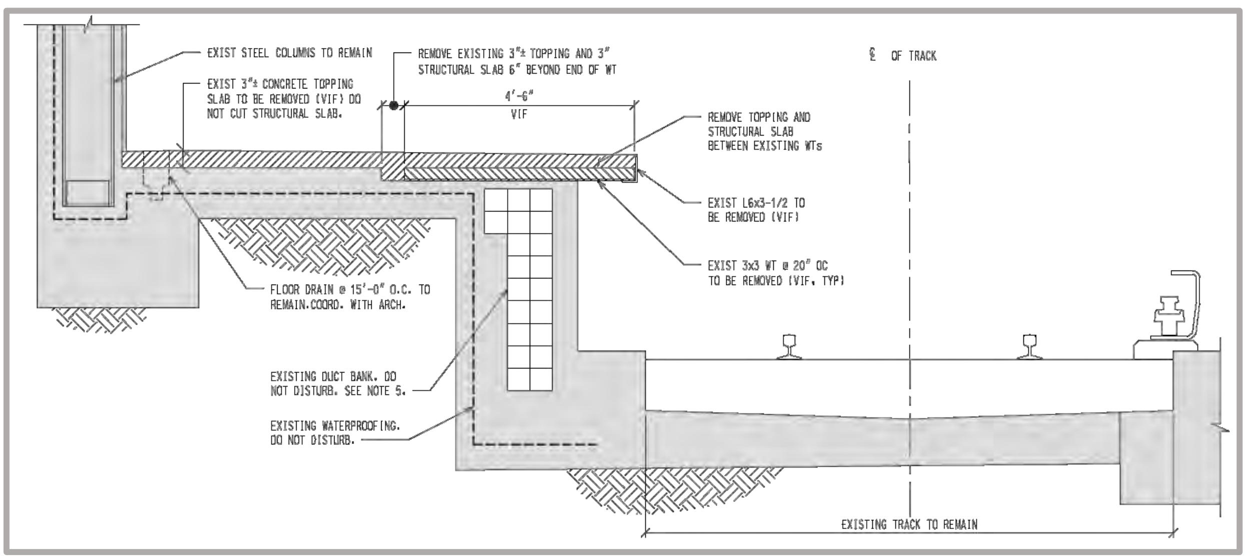

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

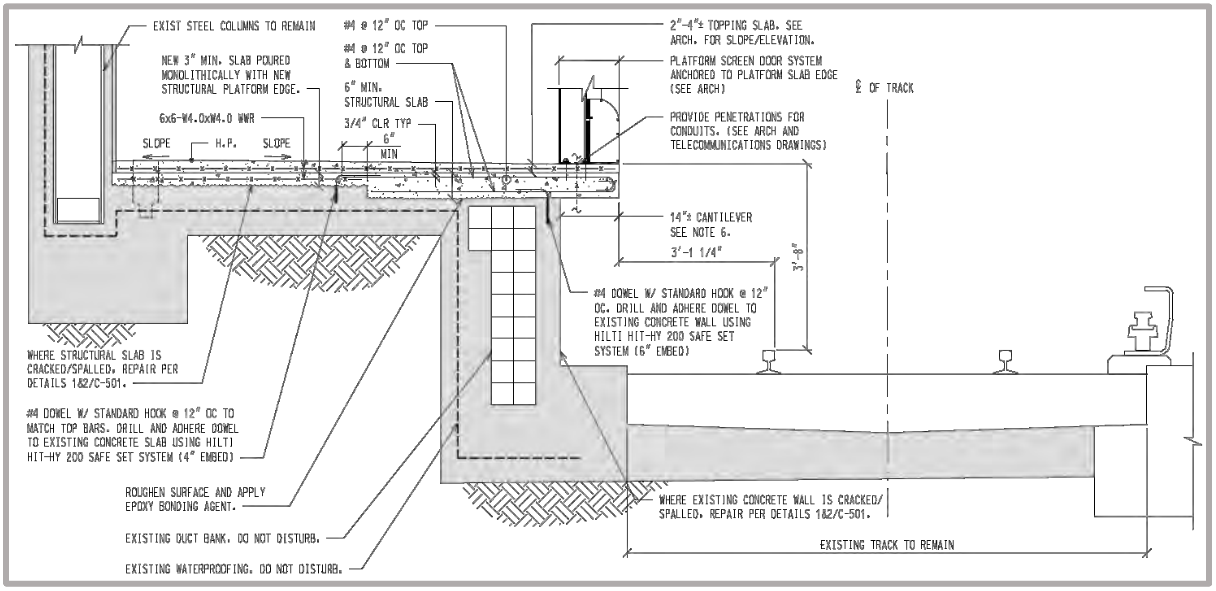

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

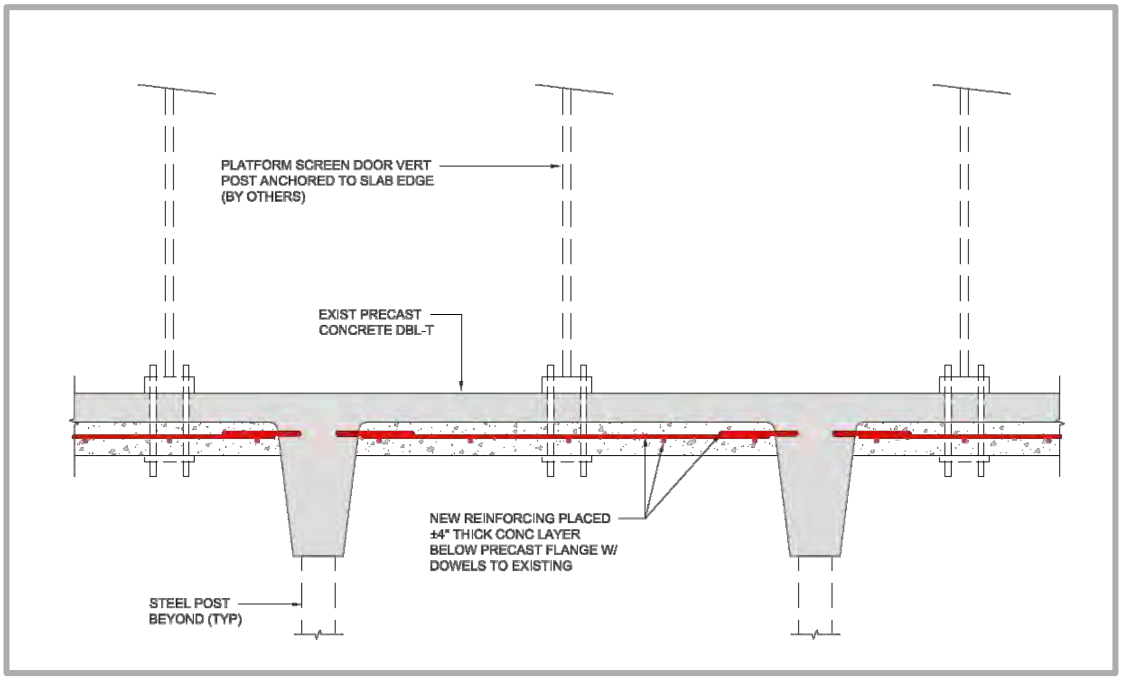

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

A CONSTRUCTION CONSULTING FIRM

Tier 2-3 Report on Feasibility of Platform Edge Barriers for G Line Stations

MTA/NYCT

August 31, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs / PSDs will provide 31 emergency egress doors with push bars per platform*
1.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.2 In respect of the PSD option, only platforms that have not been upgraded in the recent past (assuming over the past two decades) will require platform edge replacement.
2.3 There are no special security requirements made necessary by installation of the APG system
2.4 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.5 This estimate does not provide for the replacement of Platform Edge Lighting
2.6 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

Tier 2-3 Report on Feasibility of Platform Edge Barriers for G Line Stations

MTA/NYCT

August 31, 2018

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 *Below the line or "soft" costs:*

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 *Additional Notes*

5.1 *Given the limited time available, no drawings were developed to support this estimate.*

STATION: GREENPOINT AVENUE STATION

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [BROOKLYN BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,320	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	8	CARS		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,320	LF	7	9,240
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,600	SF	12	79,200
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	133	CY	2,500	332,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,322	EA	25	33,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,322	EA	25	33,050
19	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
20	Polyethylene edge strip	1,320	LF	95	125,400
21	Provide sleeves for HV & LV wires	264	EA	110	29,040
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,320	LF	15	19,800
26	Remove existing platform tiles	1,320	LF	12	15,840
27	Sawcut existing topping concrete at perimeter of removal area	1,320	LF	5	6,600
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,920	SF	8	63,360
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	1,320	SF	15	19,800

STATION: GREENPOINT AVENUE STATION

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	528	SF	15	7,920
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	384	LF	110	42,240
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	Equipment Room [6'-6" x 16'-0"]				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	29	LF	90	2,610
39	CMU Wall for equipment room	290	SF	45	13,050
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	104	SF	30	3,120
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	290	SF	40	11,600
45	Mosaic Band to match existing - Assuming 8" high	29	LF	120	3,480
46	Concrete cove to match existing	29	LF	20	580
47	Interior Wall Finish - Paint	290	SF	5	1,450
48	Allow for Misc. floor & ceiling finishes	104	SF	15	1,560
49	Allow for 4" thick concrete pads for equipment	26	SF	20	520
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54	Allowance for additional builders work (chases, coring, patching, etc.) associated with locating Equipment Room at Mezzanine Level	1	LS	10,000	10,000
55					
56	Automatic Platform Gates [APGs] - 4'-6" High				
57	Automatic bi-parting gates; Assumed 6'-0" wide (8 Cars x 4 Doors = 32 No. per platform)	64	EA	15,000	960,000
58	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #31 per Platform	62	EA	10,500	651,000
59	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
60	Platform End Gates (PEGs)	4	EA	13,000	52,000
61	Fixed Panels including framing and support; 4'-6" High	3,303	SF	750	2,477,250
62	Spare Parts - Approx. 10% of Material Cost	1	LS	250,815	250,815
63	Testing and commissioning	800	HRS	160	127,944
64	Product Warranty	1	LS	1,000,000	1,000,000
65	Allowance for Braille Signage	64	EA	2,500	160,000
66					
67	Electrical				
68	Electrical Upgrades				
69	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
70	Power and Lighting				

STATION: GREENPOINT AVENUE STATION

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
72	Allow for conduit / cable runs for power and communications under platform edge	1,320	LF	60	79,200
73	PSD Connections	1	LS	75,000	75,000
74	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
75	Power to PSD Rooms from EDR [Conduit & Cable]	100	LF	60	6,000
76	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
77	Allowance for power to cross tracks to opposite platform	1	LS	15,000	15,000
78	No allowance for new lighting as if APG's are used		Note		EXCL.
79	Grounding				
80	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
81	MISC				
82	Testing and commissioning	1	LS	30,000	30,000
83	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000
84					
85	Communications				
86	FA System				
87	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
88	CCTV coverage				
89	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
90	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
91	Berthing Technology Sensors				
92	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	8	EA	16,000	128,000
93	Train Door Detection System				
94	Train Door Detection Sensor including software and hardware requirements	8	EA	15,000	120,000
95	Entrapment concerns				
96	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	192	EA	4,629	888,814
97	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	192	EA	5,566	1,068,588
98	Engineering and Testing	2,000	Hrs	160	319,860
99	Centralized monitoring/control				
100	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
101	MISC				
102	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000

31-Aug-18

STATION: FLUSHING AVE MARCY AV

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [BROOKLYN BOUND] =	660	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	660	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,320	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	8	CARS		
8

Operations Planning Meeting

Issued: 8/09/18

C–32516: Platform Screen Door (PSD) System-Wide Feasibility Study

MEETING PURPOSE: Vehicle Assignments on G-Service – Impact to PSD Feasibility Study

MEETING DATE: August 9, 2018

ATTENDEES:

Don Willemann	NYCT – CPM Systems & Security
Glenn Lunden	NYCT – Operations Planning
David Foell	STV
Liz Opper	STV
Khaled Mohamed	STV

Meeting Minutes

Issue / Action Description

VEHICLE ASSIGNMENTS TO G-LINE:

The purpose of the meeting was to establish an assumed future vehicle assignment for G-train service encompassing the PSD feasibility study design year of 2032.

1) Glenn Lunden made the following observations in regard to this subject:

   a. Current G-trains are 300' long each (four 75-foot cars).

   b. As part of the L-train (Canarsie Line) shutdown mitigation in 2019, the trains are to be lengthened to eight 60-foot cars.

   c. Current expectations are for the eight 60-foot car assignments to remain permanently after the Canarsie Line is restored to service; this has not been confirmed by senior NYCT management, but should be assumed for the purposes of this analysis.

   d. F-train service is occasionally diverted to the G-train line when there are significant traffic issues in Manhattan. The F-trains utilize 10-car trains, comprised of 60-foot cars.

   e. There are no plans to lengthen G-trains to use a 10-car train.

2) It was noted that 10-car trains and 8-car trains cannot share a PSD system due to dimensional differences in the door placement in the A-car and B-car of the respective train consists. Therefore, any PSD system oriented toward the G-train 8-car train would preclude the possibility of an F-train stopping at any of the G-train service stations.

3) **Conclusion:** it was decided to study PSD installation assuming usage by only the 8-car G-train. The feasibility report will note that future diversions of F-train service will be precluded or limited to thru-service without any stops between Queens Plaza, Queens, and Hoyt Schermerhorn in downtown Brooklyn (a 12-station bypass).

MTA New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'JZ' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: October 17, 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 30 newly evaluated stations, 24 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at Sutphin Blvd and Jamaica Center/ Parsons. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings, and shows that platform edge barriers are feasible at 20% of the 'JZ' Line stations. Total implementation cost would be $170.0M for APGs and $213.8M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 6 feasible stations, the aggregate annual maintenance cost would be $5.6M.

Summary Table

1.0 Station Assessments

1.01 – MRN 080 | 121st Street Station

Summary: *121st Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

121st Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-10" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 28" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 13" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
121st Street Station

1.02 – MRN 081 | 111st Street Station

Summary: *111st Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

111st Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-10" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 24" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 9" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
111st Street Station

1.03 – MRN 082 | 104th Street Station

Summary: *104th Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

104th Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 8'-0" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 24" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 9" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

***Figure 1** – Non-Compliant ADA condition*
104th Street Station

1.04 – MRN 083 | Woodhaven Boulevard Station

Summary: *Woodhaven Boulevard Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Woodhaven Boulevard Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-10" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 20" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 5" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
Woodhaven Boulevard Station

Table of Contents

1.05 – MRN 084 | 85th Street-Forest Parkway Station

Summary: *85th Street-Forest Parkway Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

85th Street-Forest Parkway Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-10" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 20" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 5" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

***Figure 1** – Non-Compliant ADA condition*
85th Street-Forest Parkway Station

1.06 – MRN 085 | 75th Street-Elders Lane Station

Summary: *75th Street-Elders Lane Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

75th Street-Elders Lane Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-8" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 24" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 5" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

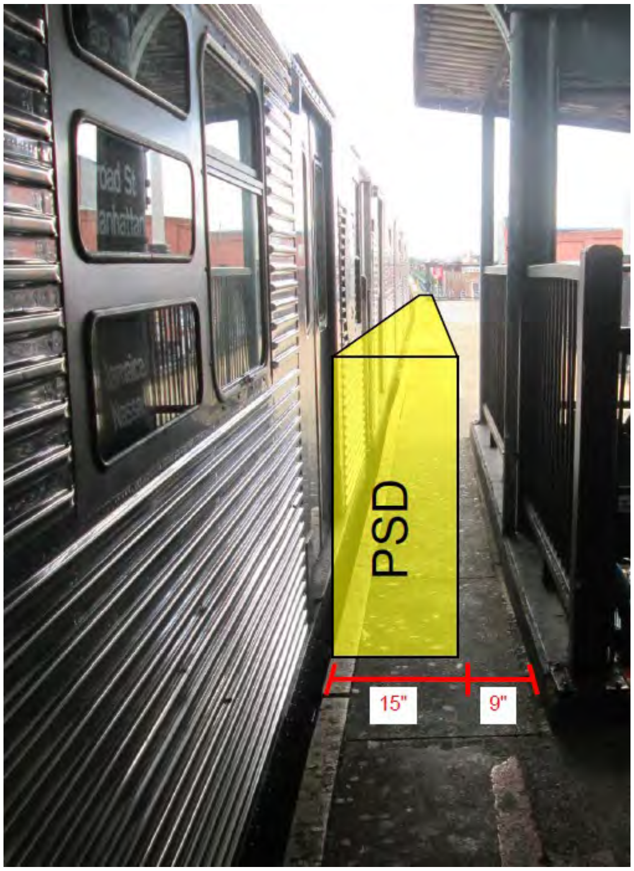

Figure 1 *– Non-Compliant ADA condition*
75th Street-Elders Lane Station

1.07 – MRN 086 | Cypress Hills Station

Summary: *Cypress Hills Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Cypress Hills Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 7'-8" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 22" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 7" would not allow for ADA compliant wheelchair movement nor normal passenger movement. See figure 1 for reference.

Table of Contents

1.08 – MRN 087 | Crescent Street Station

Summary: *Crescent Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Crescent Street Station is an elevated station consisting one center/island platform. The platform is approximately 17'-0" wide. The platform is straight with a row of a columns in the center of the platform, which support the station canopy. The canopy covers approximately a third of the platform length. See figure 1 for reference.

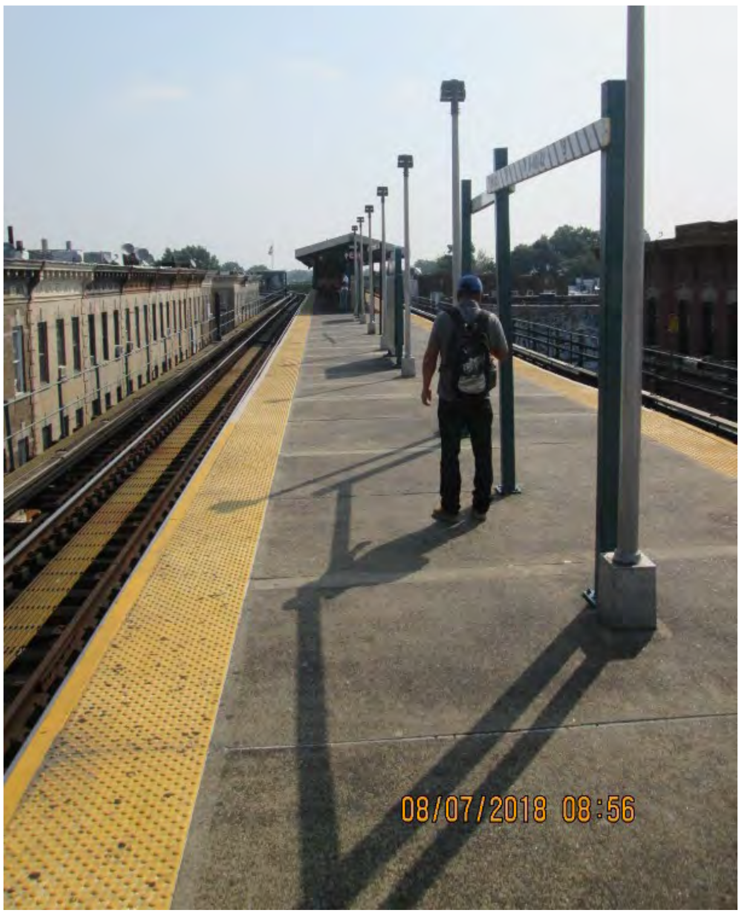

Figure 1 *– Precast platform*
Crescent Street Station

1.09 – MRN 088 | Norwood Avenue Station

Summary: *Norwood Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Norwood Avenue Station is an elevated station consisting one center/island platform. The platform width varies from approximately 12'-6" to17'-0" wide. The platform is straight with a row of a columns in the center of the platform, which support the station canopy. The canopy covers a quarter of the platform length. See figure 1 for reference.

Figure 1 *– Precast platform*
Norwood Avenue Station

Table of Contents

1.10 – MRN 089 | Cleveland Street Station

Summary: *Cleveland Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Cleveland Street Station is an elevated station consisting one center/island platform. The platform width is approximately 13-0" wide. The platform is straight with a row of a columns in the center of the platform, which support the station canopy. The canopy covers a quarter of the platform length. See figure 1 for reference.

***Figure 1** – Precast platform*
Cleveland Street Station

1.11 – MRN 090 | Van Siclen Avenue Station

Summary: *Van Siclen Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Van Siclen Avenue Station is an elevated station consisting one center/island platform. The platform width is approximately 14-6" wide. The platform is straight with a row of a columns in the center of the platform, which support the station canopy. The canopy covers a quarter of the platform length. See figure 1 for reference.

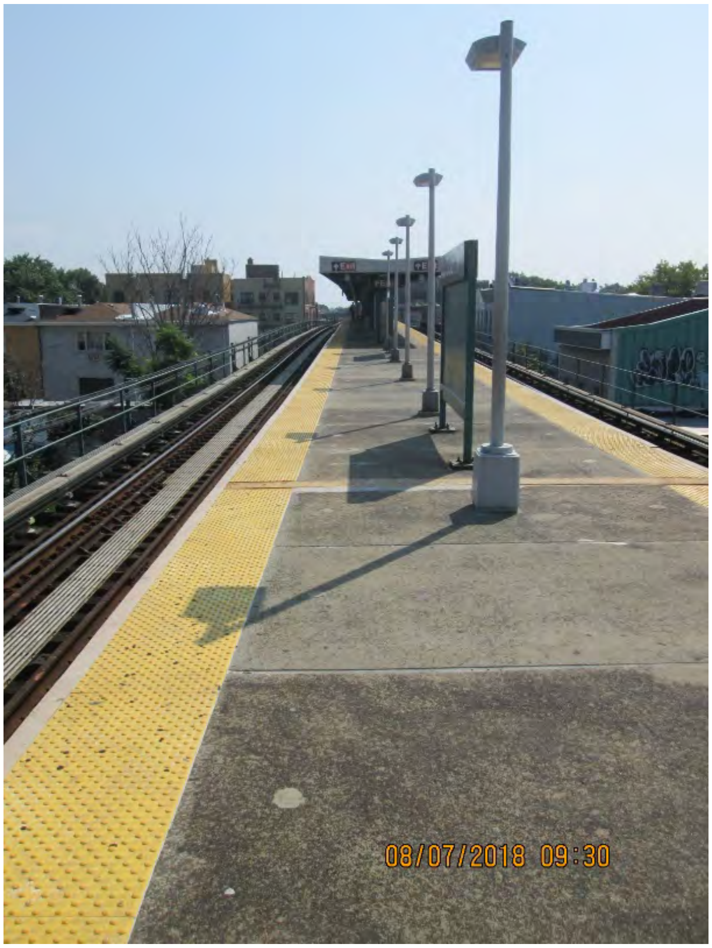

Figure 1 *– Precast platform*
Van Siclen Avenue Station

1.12 – MRN 091 | Alabama Avenue Station

Summary: *Alabama Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Alabama Avenue Station is an elevated station consisting one center/island platform. The platform width is approximately 14-6" wide. The platform is straight with a row of a columns in the center of the platform, which support the station canopy. The canopy covers a quarter of the platform length. See figure 1 for reference.

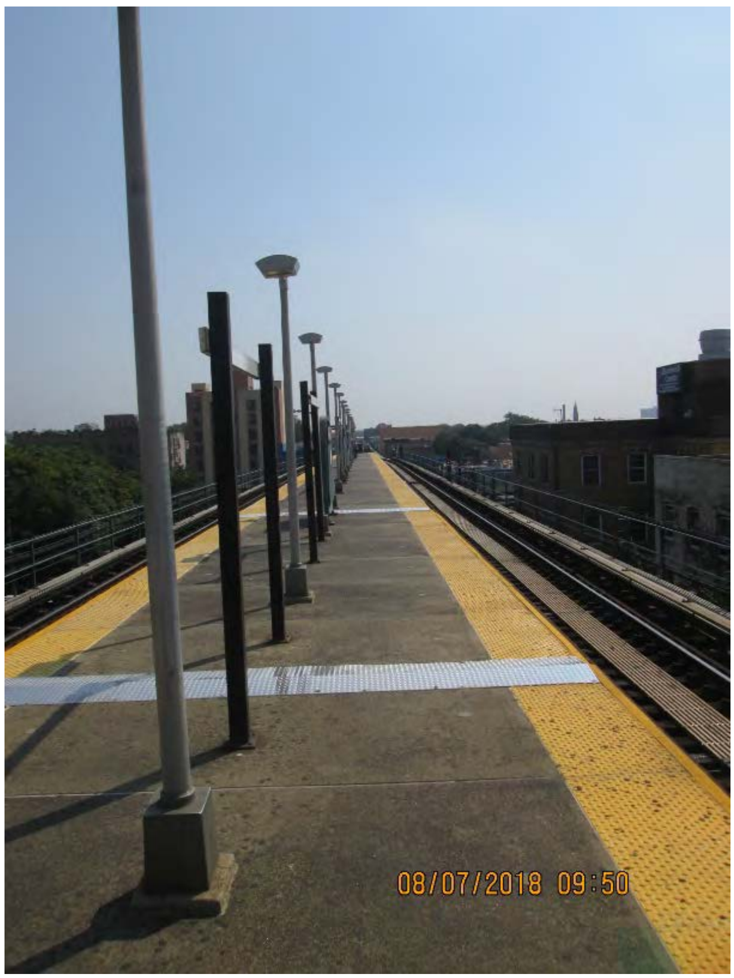

Figure 1 *– Precast platform*
Alabama Avenue Station

1.13 – MRN 092 | Broadway Junction Station

Summary: *Broadway Junction Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Broadway Junction Station is an elevated station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 14'-0" throughout. There are three staircases throughout each of the platforms. Columns are spaced 15'-0" on center and flank the staircases on both sides. Columns measure 3'-6" away from all platform edges. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

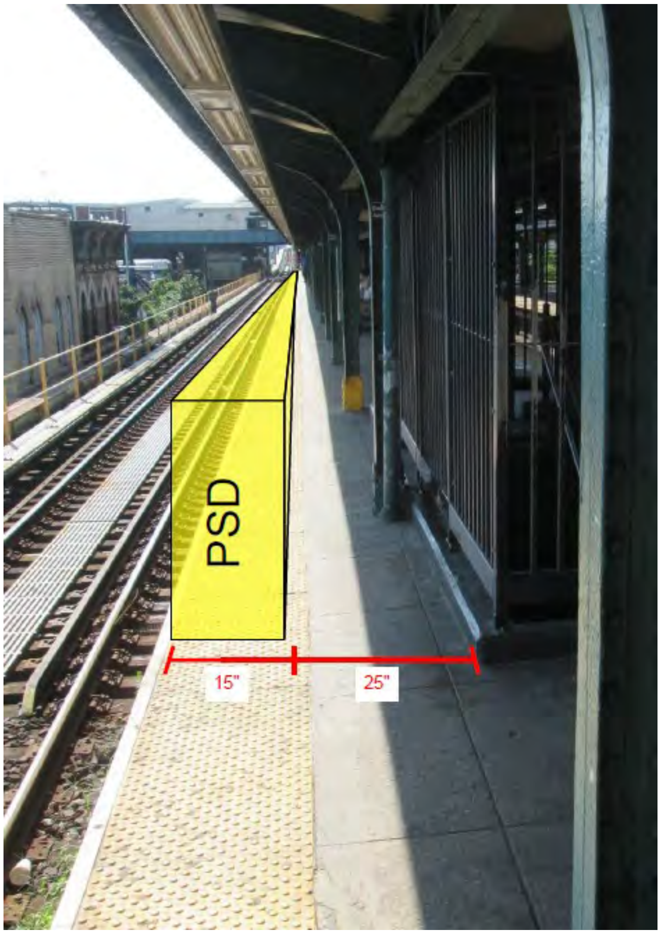

Figure 1 *– Non-Compliant ADA condition*
Broadway Junction Station

1.14 – MRN 093 | Chauncey Street

Summary: *Chauncey Street is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Chauncey Street is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-6" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

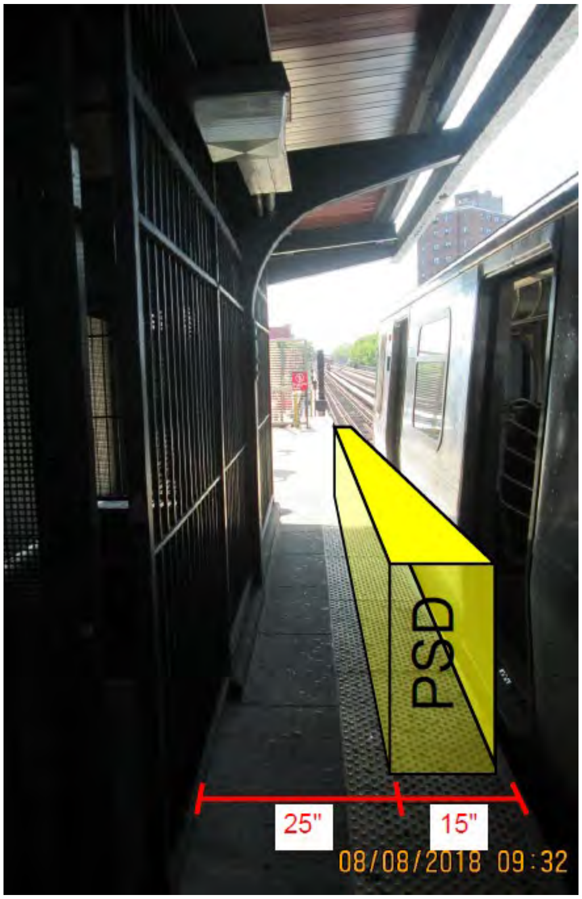

***Figure 1** – Non-Compliant ADA condition*
Chauncey Street

1.15 – MRN 094 | Halsey Street Station

Summary: *Halsey Street is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Halsey Street is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-6" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

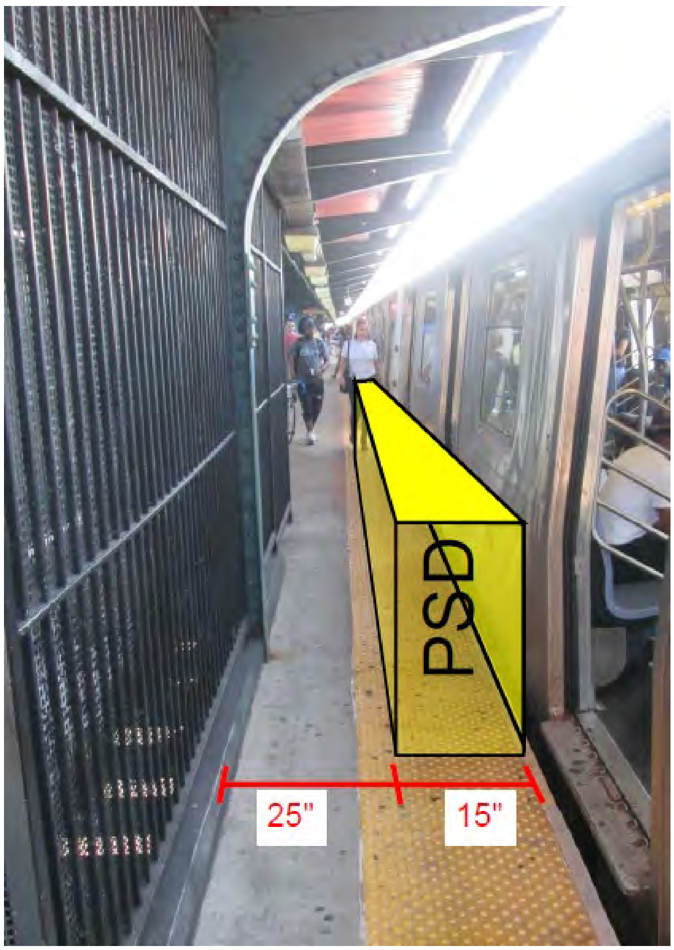

Figure 1 *– Non-Compliant ADA condition*
Halsey Street

1.16 – MRN 095 | Gates Avenue Station

Summary: *Gates Avenue is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Gates Avenue is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-6" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
Gates Avenue

1.17 – MRN 096 | Kosciusko Street Station

Summary: *Kosciusko Street is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Kosciusko Street is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-6" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

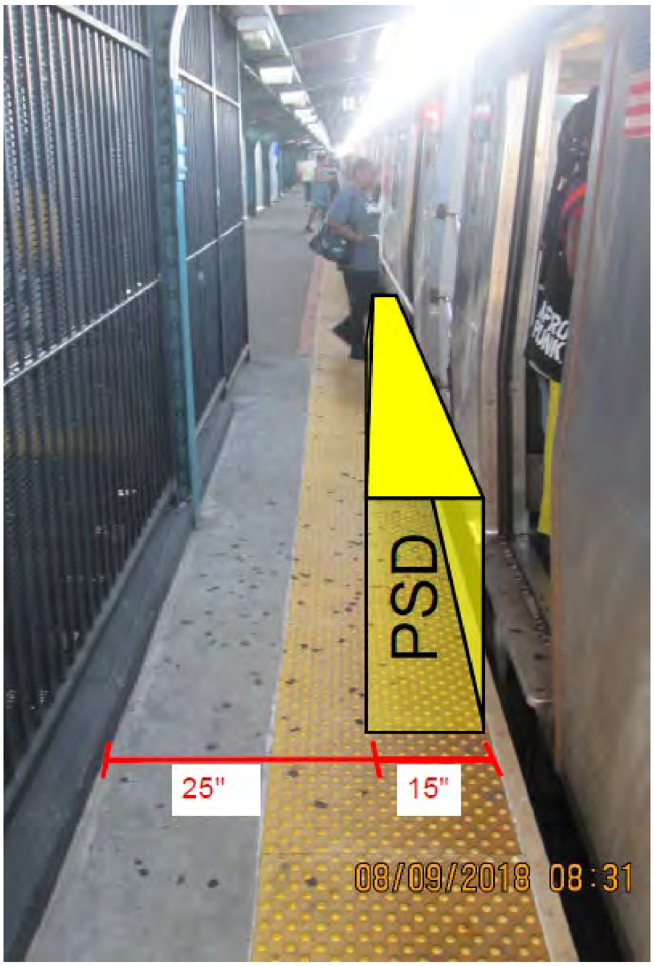

***Figure 1** – Non-Compliant ADA condition*
Kosciusko Street

1.18 – MRN 097 | Myrtle Avenue-Broadway Station

__Summary:__ Myrtle Avenue-Broadway Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.

Description

Myrtle Avenue-Broadway Station is an elevated station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 14'-0" throughout. There are three staircases throughout each of the platforms. Columns are spaced 15'-4" on center and flank the staircases on both sides. Columns measure between 3'-10" and 2'-10" away from all platform edges. Currently the stair guardrail and columns sit 46" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 31" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

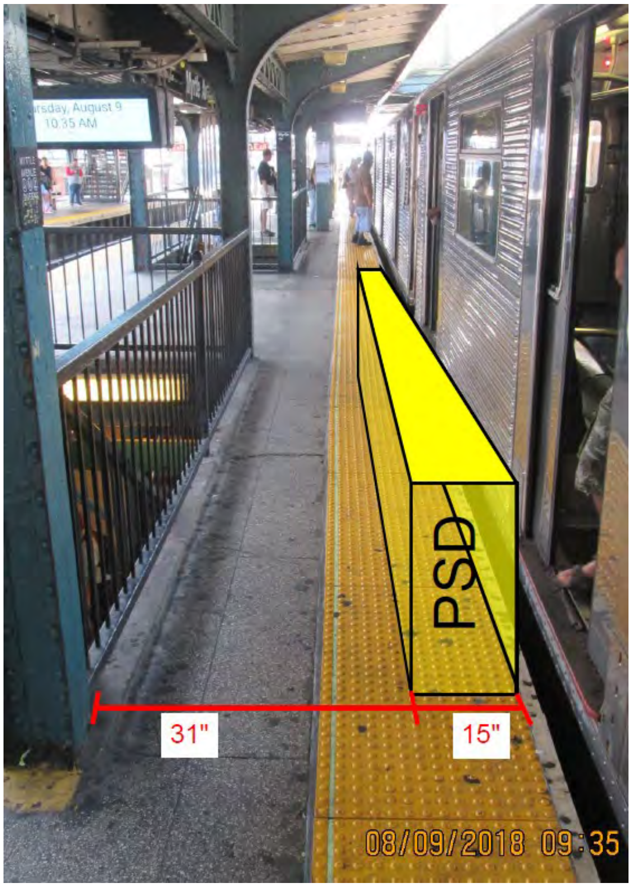

***Figure 1** – Non-Compliant ADA condition*
Myrtle Avenue-Broadway Station

1.19 – MRN 098 | Flushing Avenue Station

Summary: *Flushing Avenue Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Flushing Avenue Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-2" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

***Figure 1** – Non-Compliant ADA condition*
Flushing Avenue Station

1.20 – MRN 099 | Lorimer Street Station

Summary: *Lorimer Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Lorimer Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-4" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

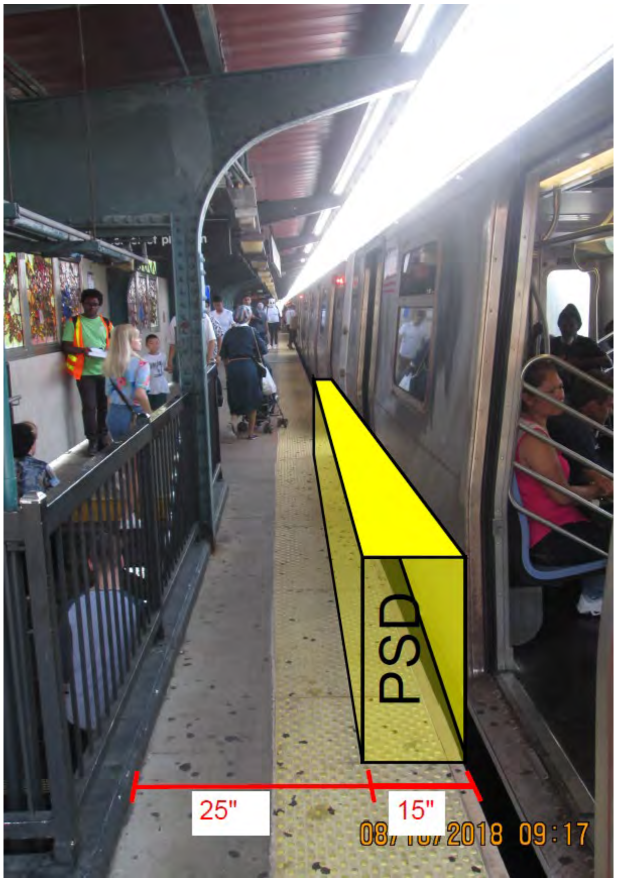

Figure 1 *– Non-Compliant ADA condition*
Lorimer Street Station

1.21 – MRN 100 | Hewes Street Station

Summary: *Hewes Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Hewes Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 9'-8" throughout. There are two staircases at each end of the platforms. Currently the stair guardrail sits 40" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36" at all staircases. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

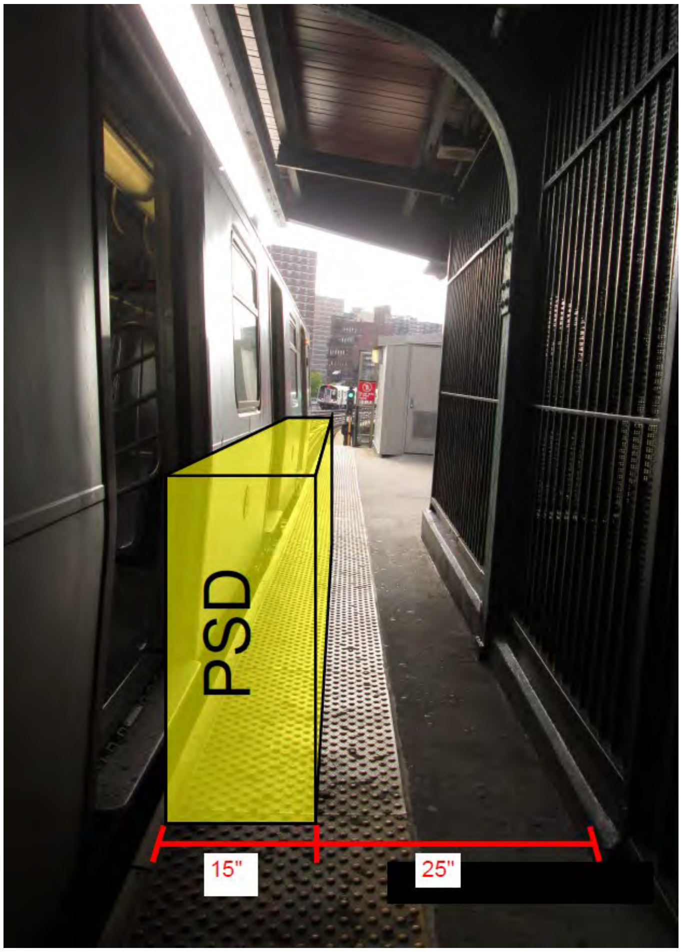

***Figure 1** – Non-Compliant ADA condition*

Table of Contents

1.22 – MRN 101 | Marcy Avenue Station

Summary: *Marcy Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description

Marcy Avenue Station is an elevated station consisting of two side platforms. The platform widths are approximately 10'-0". The platforms are straight with a row of a columns in line with the wind screen, which support the station canopy. The canopy covers a half of the platform length. See figure 1 & 2 for reference.

Figure 1 *– General Station condition*
Marcy Avenue Station

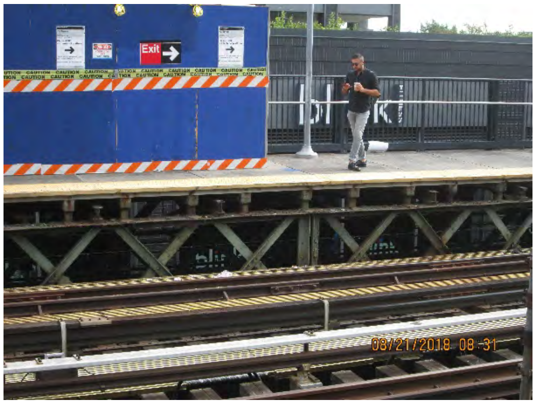

Figure 2 *– Precast Slab*
Marcy Avenue Station

1.23 – MRN 102 | Delancey Street - Essex Street Station

Summary: *Delancey Street - Essex Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Delancey Street - Essex Street Station is a below grade station with 1 straight center/island platforms & 1 Side platform. The platform structures are cast-in-place concrete. The width of the side platform is approximately 22-0" throughout - columns are spaced 15'-0" on center and measure 2'-8" from column face to platform edge. The width of the center/island platform is approximately 16'-4" throughout with columns spaced 15'-0" on center and measuring between 2'-6" and 3'-0" from column face to platform edge. On the center/island platform the columns flank multiple staircases and their presence would not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. At staircase PL-18 this condition is observed where the column faces measures 30" from the platform edge. The implementation of a platform edge barrier would reduce this width to 15" which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

***Figure 1** – Non-Compliant ADA condition*
Delancey Street - Essex Street Station

1.24 – MRN 103 | Bowery Station

Summary: *Bowery Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the structural loads of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Bowery Station is a below-grade station with one open center/island platform and one closed center/island platform **(see Figure 1)**. The platform structures are cast-in-place concrete. At the open platform columns are spaced 15'-0" on center with column faces ranging from 2'-6" to 4'-8" from the platform edge. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling height varies throughout the station.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the closed northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures. **(See Figure 3)**

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.000. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

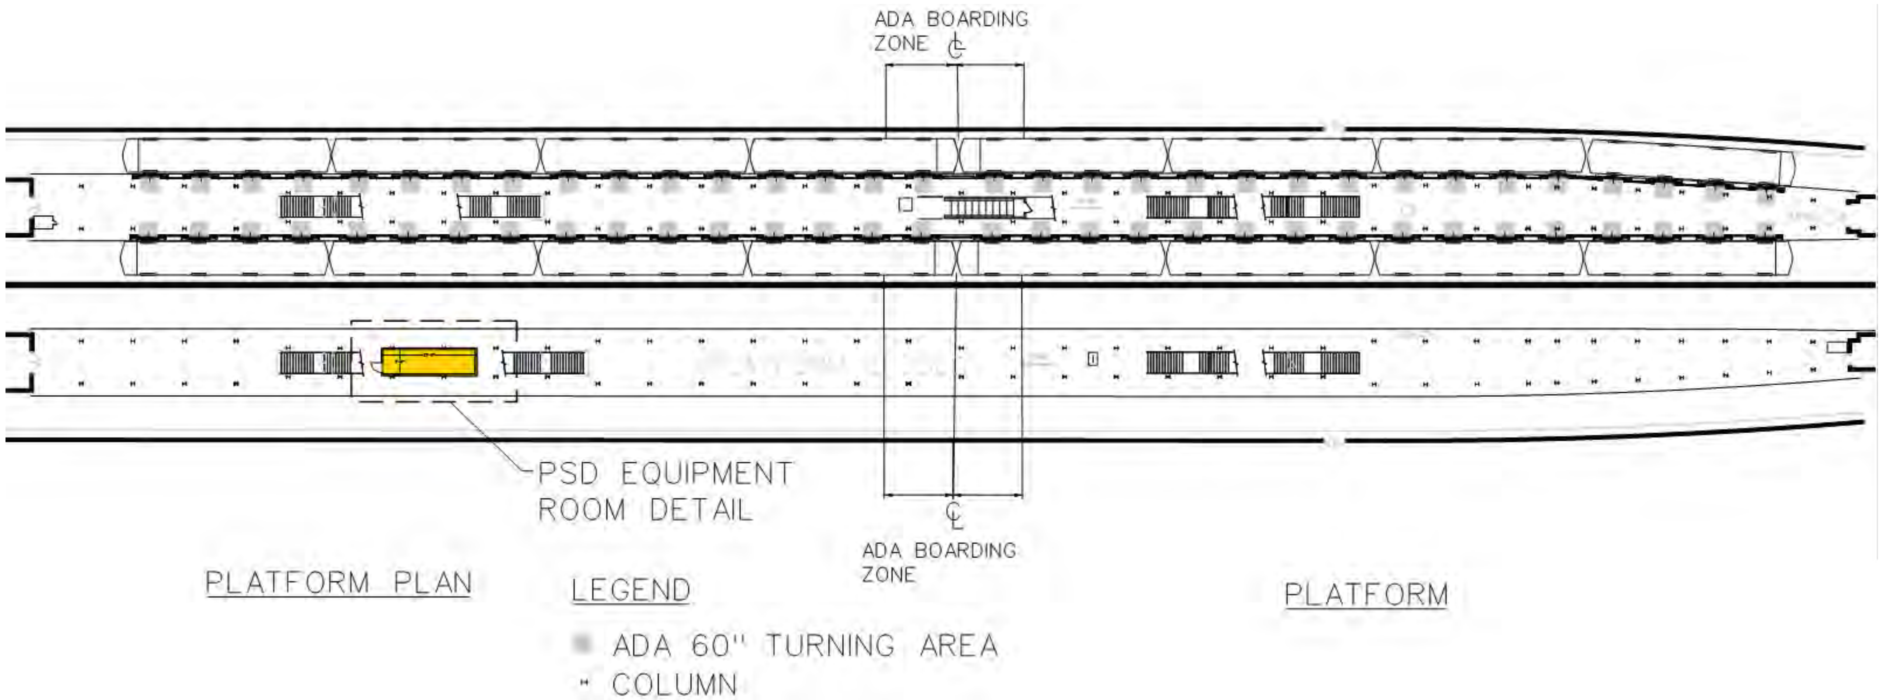

***Figure 1** – Overall Station Plan*
Bowery Station

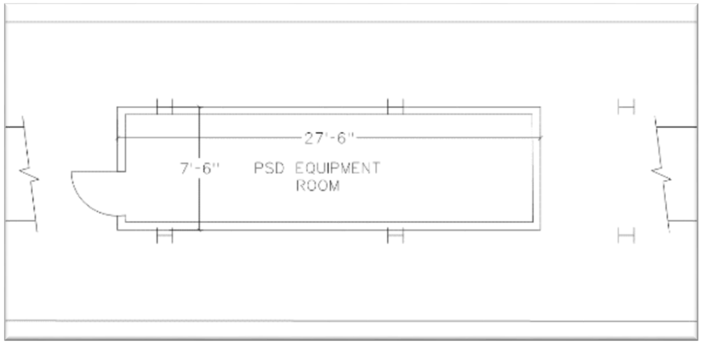

***Figure 2** – PSD Equipment Room 1 Detail*
Bowery Station

***Figure 3** – Typical platform view*
Bowery Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; perpendicular to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Bowery
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	56.4
Apparent Power (kVA)	70.5
Station Peak Demand Load, Max Current, (A)	195.8
Maximum Amount of Doors	64.0
PSD Total Load Including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	361
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	439
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on 1 line diagram. The analysis is based on available one Normal meter reading. (No access to Tunnel Reserve room)

Table 1*- Power Capacity Analysis*

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.6M to install APGs and $35.6M to install PSDs (See Appendix E)

Table of Contents

1.25 – MRN 104 | Canal Street Station

Summary: *Canal Street Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Canal Street Station is a below-grade station with one open center/island platform and one closed center/island platform **(see Figure 1)**. The platform structures are cast-in-place concrete. At the open platform the platform width is approximately 19"-0" and columns are spaced 15'-0" on center with column faces measuring approximately 4'-6" from the platform edge. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling height varies throughout the station.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the closed northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are tangent. We are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.750. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair

Total Load (Station Peak + PSD), (A)	390
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	410
Is Electrical Service Adequate?	**Yes**
	Service rating is based on 1 line diagram. The Station has only normal EDR and one Normal meter reading.

Table 1- *Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $26.6M to install APGs and $32.5M to install PSDs (See Appendix E).

1.26 – MRN 105 | Chambers Street Station

Summary: *Chambers Street Station is not feasible for both APGs and PSDs. Current conditions at various locations in this station do not meet ADA compliance requirements. The implementation of an APG/PSD system would further constrain the aforementioned non-compliant locations.*

Description

Chambers Street Station is below grade station with two active straight center/island platforms, 1 closed center/island platform and 2 closed side platforms. The platform structures are cast-in-place concrete. The width of the open platforms is approximately 22'-8" throughout. Columns are spaced 15'-0" on center and measure between 2'-6" and 3'-6" away from all platform edges. The platform columns flank multiple staircases and their presence would not allow for the 32" pinch-point width required for wheelchair movement with PSDs installed. At staircase P43A/B this condition is observed where a column face measures 40" from the platform edge. The implementation of a platform edge barrier would reduce this width to 25". See figure 1 for reference.

Figure 1 *– Non-Compliant ADA condition*
Chambers Street Station

1.27 – MRN 106 | Fulton Street Station

Summary: *Fulton Street Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Fulton Street Station is a below-grade station with two mildly curved side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-4" from the platform edge. The southbound platform width varies from approximately 14'-0" to 17'-8". The northbound platform width is approximately 14'-6" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling height varies throughout the station.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound platform in a closed control area (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are on a mild radius. Therefore, the gaps between the platform and train will slightly exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Reserve service**.

Table 1- *Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be \$27.4M to install APGs and \$34.1M to install PSDs (See Appendix E)

1.28 – MRN 107 | Broad Street Station

Summary: *Broad Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located above the each platform edge with a vertical clearance ranging between 7' 4" and 8'-0", which would require relocation to implement a PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see structural report; Appendix B). At the time of this report's submission, no electrical data could be ascertained. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

Broad Street Station is a below-grade station with two mildly curved side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound platform width varies from approximately 8'-6" to 20'-0". The northbound platform width varies from approximately 10'-8" to 20'-2". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The ceiling height varies throughout the station. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northbound platform, flush to the wall (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-0" x 6'-6".

Track Layout

Tracks are on a mild radius. Therefore, the gaps between the platform and train will slightly exacerbate the gap between the train doors and the PSDs. Per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

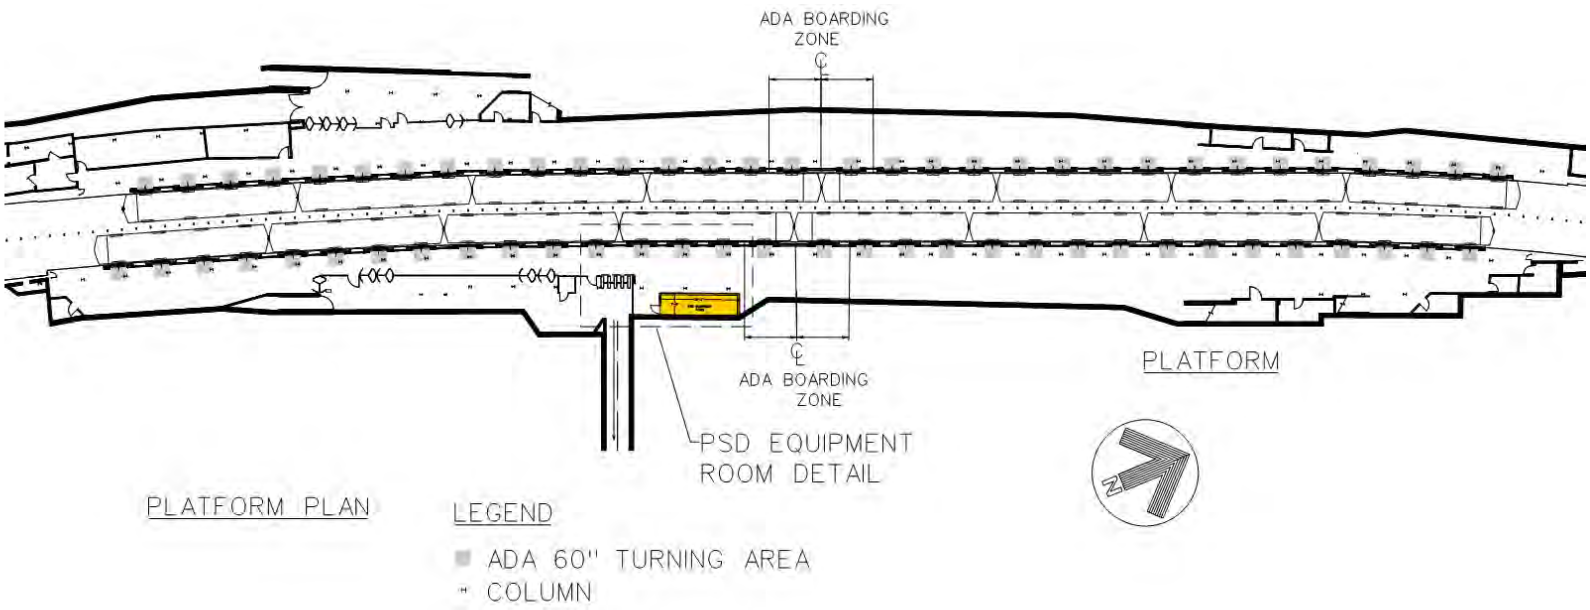

Figure 1 *– Overall Station Plan*
Broad Street Station

Broad Street Station

Figure 3 *– Typical platform view*
Broad Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; perpendicular to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed at the time of this report's submission. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.4M to install APGs and $34.1M to install PSDs (See Appendix E)

1.29 – MRN 278 | Jamaica Center– Parsons/Archer Station

Summary: *Parsons Boulevard Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Jamaica Center– Parsons Archer is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The platform structure is cast-in-place concrete. Back-of-house elements are located in the mezzanines, throughout the platform level (in non-public rooms) or at the platform ends away from the circulation paths. This report covers only the lower level platform as the upper level platform services the "E" line and was previously covered in the report for the "E" Line stations. There are sparsely located columns throughout the station. These columns are either centered and measure 20'-10" apart on center and their faces measure 11'-8" from the platform edges or the columns flank the escalators measure 25'-0" on center and their faces measure 4'-10" from the platform edge. The platform width is approximately 25'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. The varying ceiling heights throughout the station.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the center of the platform (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 7'-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 3.375. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'JZ' Line Stations
(Jamaica Center - Parsons/Archer Station)

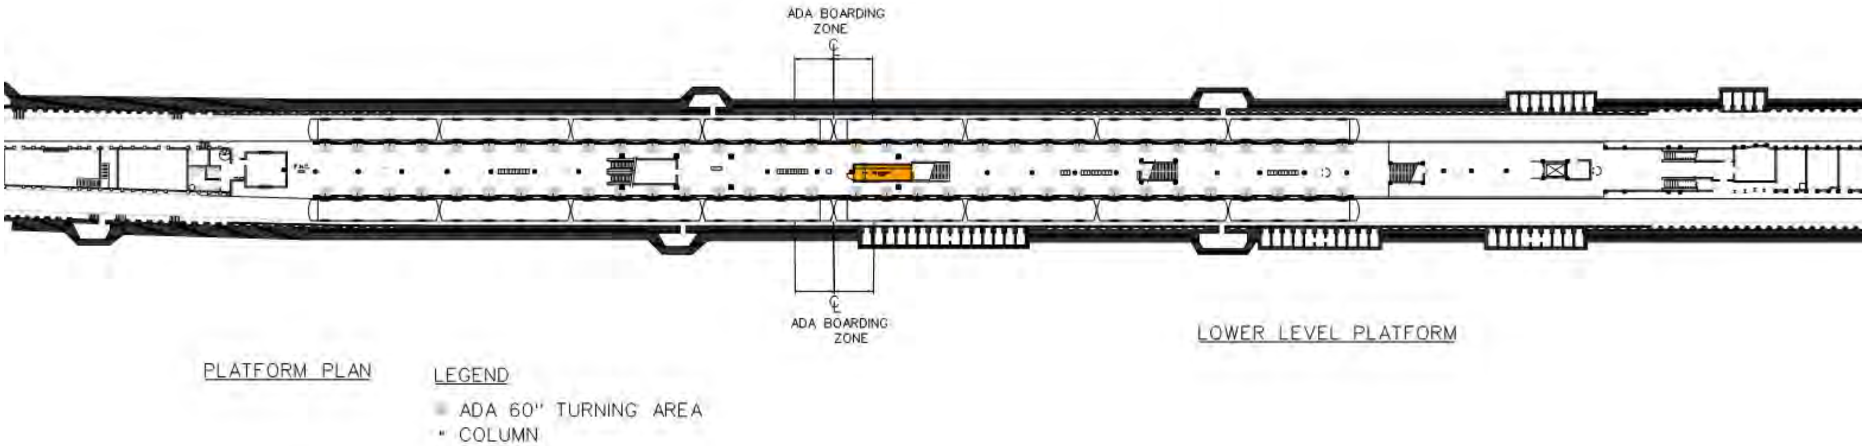

***Figure 1** – Overall Station Plan (Lower Level)*
Jamaica Center– Parsons Archer Station

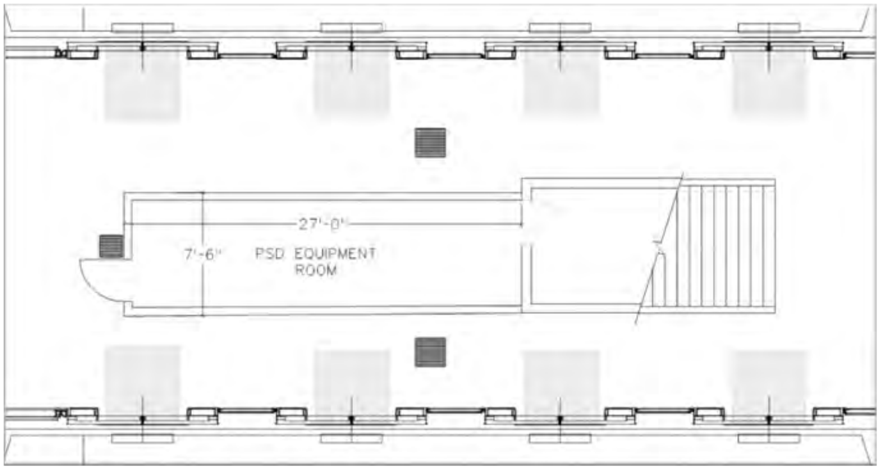

***Figure 2** – PSD Equipment Room 1 Detail*
Jamaica Center– Parsons Archer Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns at stairs and escalators

Northbound Track:

- Columns at stairs and escalators

These obstructions do not present an impediment to the installation of PSDs.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Jamaica Ctr. Parsons / Archer
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	688.3
Apparent Power (kVA)	860.4
Station Peak Demand Load, Max Current, (A)	2389.9
Maximum Amount of Doors	144.0
PSD Total Load Including All Miscellaneous Loads, (A)	317.2
Total Load (Station Peak + PSD), (A)	2707
Station Service Power Capacity, (Main SB or SG Rating), (A)	9000
Service Spare Capacity, (A)	6293
Is Electrical Service Adequate?	**Yes**
Notes	The analysis is based on field observed framed 1 line diagram located in Normal EDR. The station has only Normal EDR. The station has (2) service take offs (2 services) each at 4500 A rating and has (2) meters with combined reading.

***Table 1**- Power Capacity Analysis*

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.2M to install APGs and $38.8M to install PSDs (See Appendix E)

Jamaica Center– Parsons Archer Station

1.30 – MRN 279 | Sutphin Boulevard Station

Summary: *Sutphin Boulevard Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate*

Description

Sutphin Boulevard Station is a below-grade station with two levels of center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Back-of-house elements are located in the mezzanines or at the platform ends away from the circulation paths. This report only covers the lower level platform as the upper level platform services the "E" line and was previously covered in the report for the "E" Line stations. At the lower level platform column faces typically measure 4'-10 from the platform edge. The platform width varies from 20'-5" to 33'-9" throughout save for a slight taper to 14'-3" at the western end. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, standard NYCT wayfinding signage and the varying ceiling heights throughout the station. **(See figure 3).**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room could be located at the end of the platform (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are nearly tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG or PSD system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.875. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	Comments
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

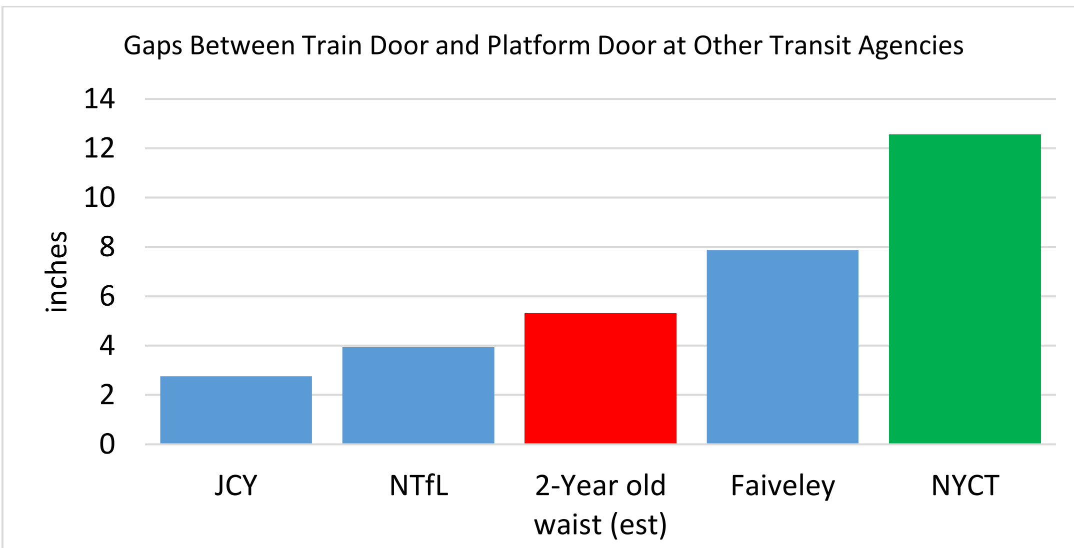

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

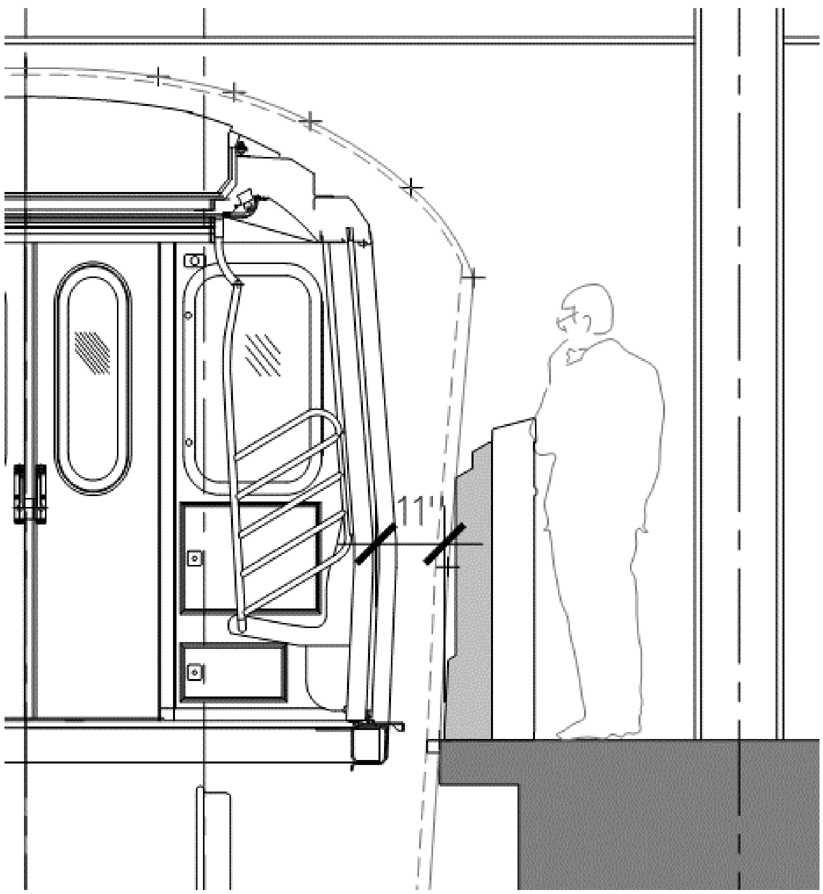

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

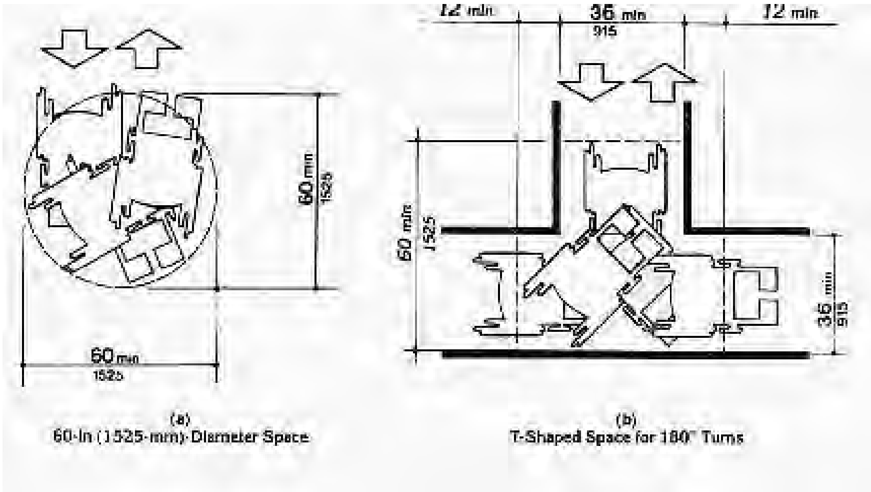
Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

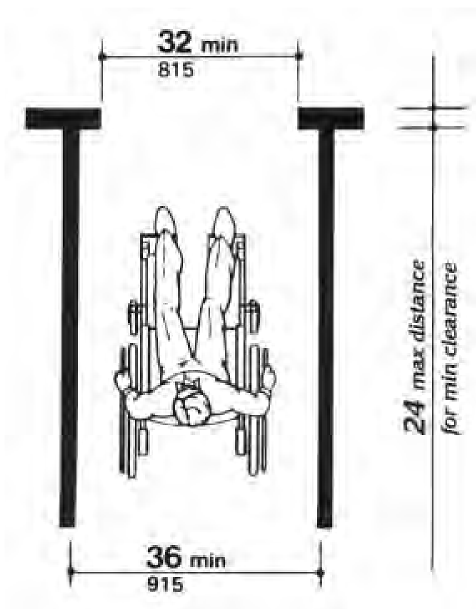


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

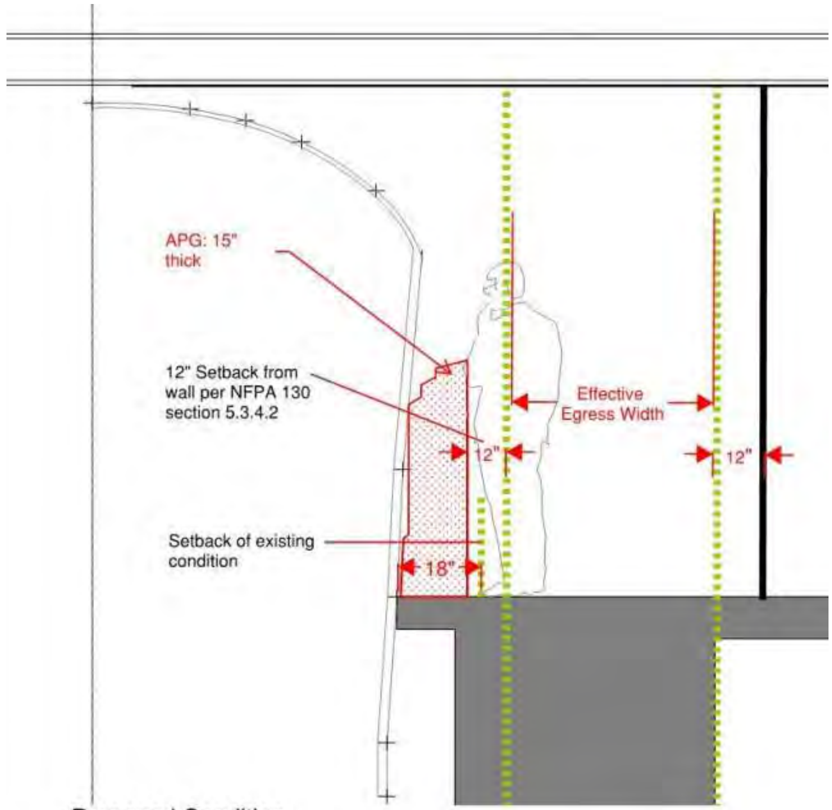
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

End of Appendix

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

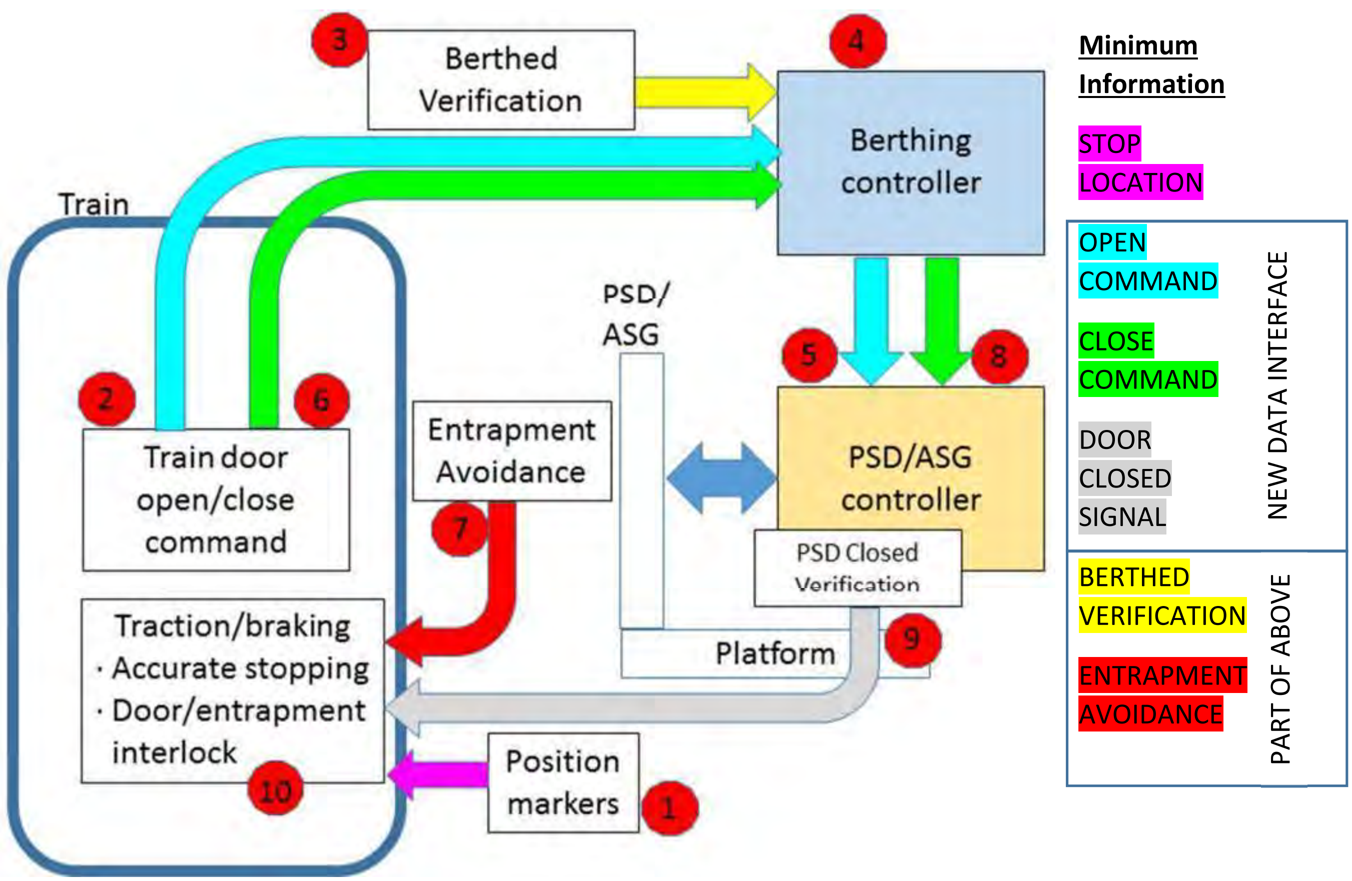
1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

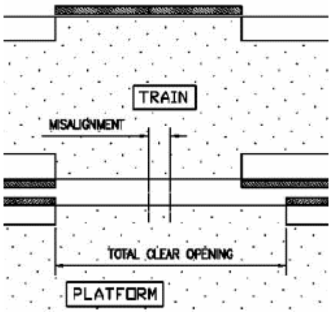
General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.
B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.
C. Dwell during passenger boarding/alighting
D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.
E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

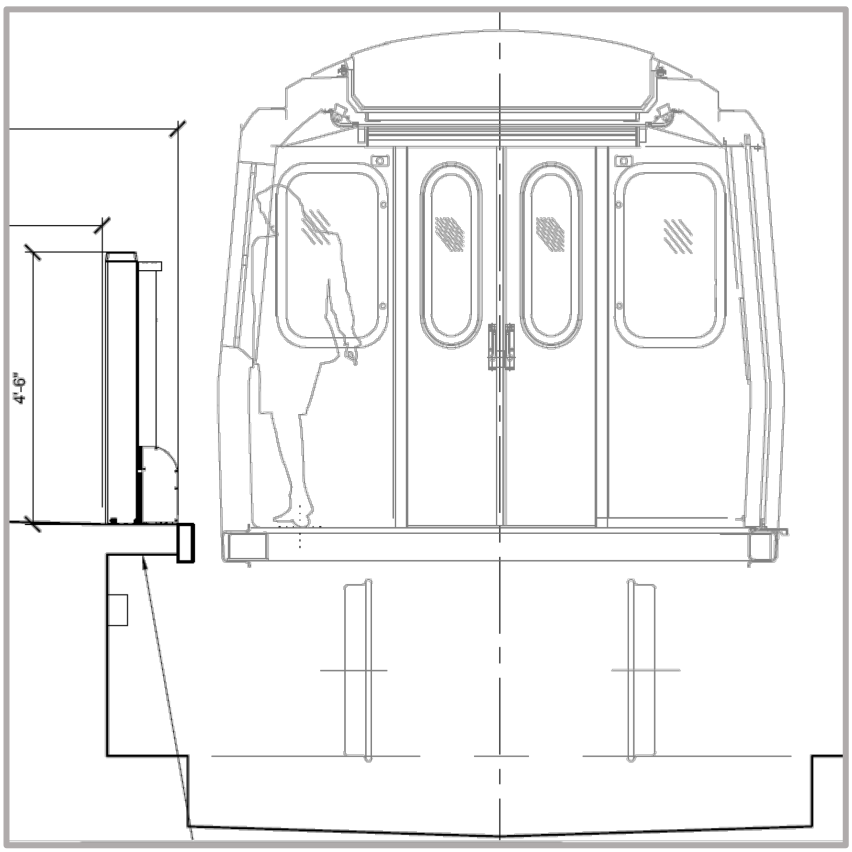


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

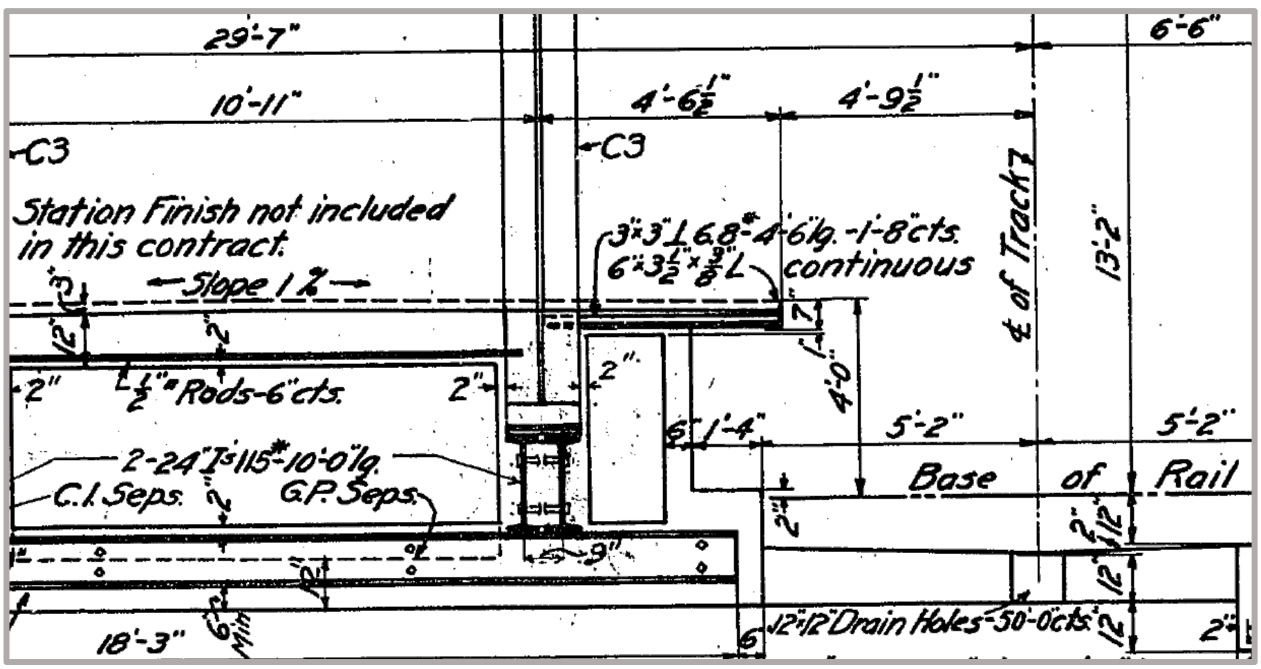

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

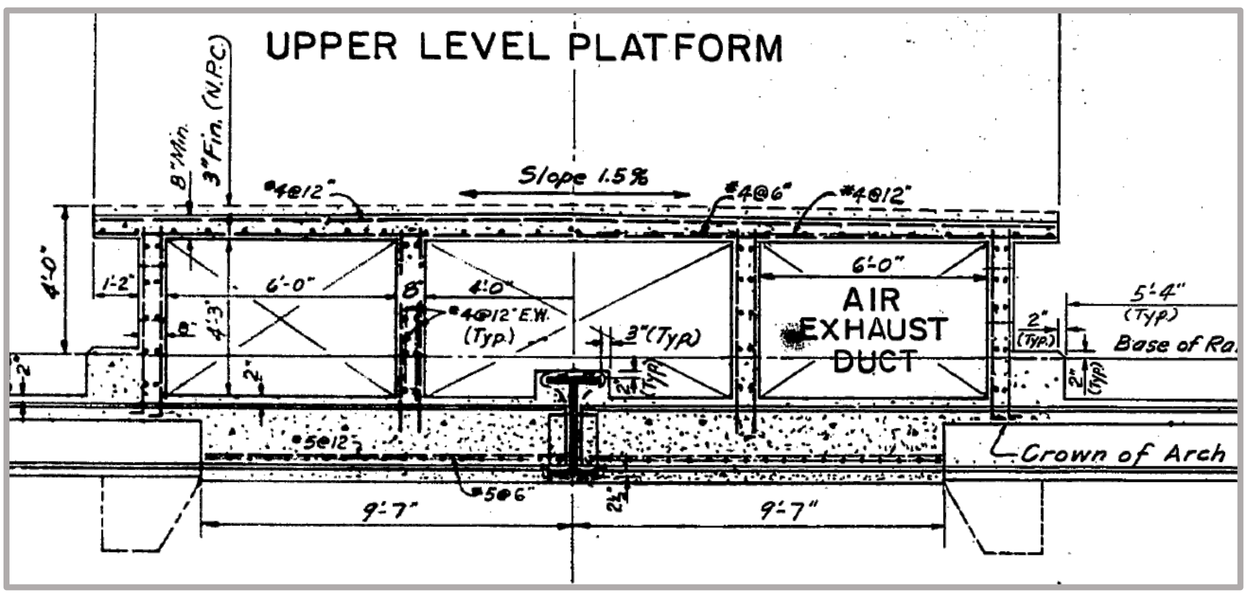

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

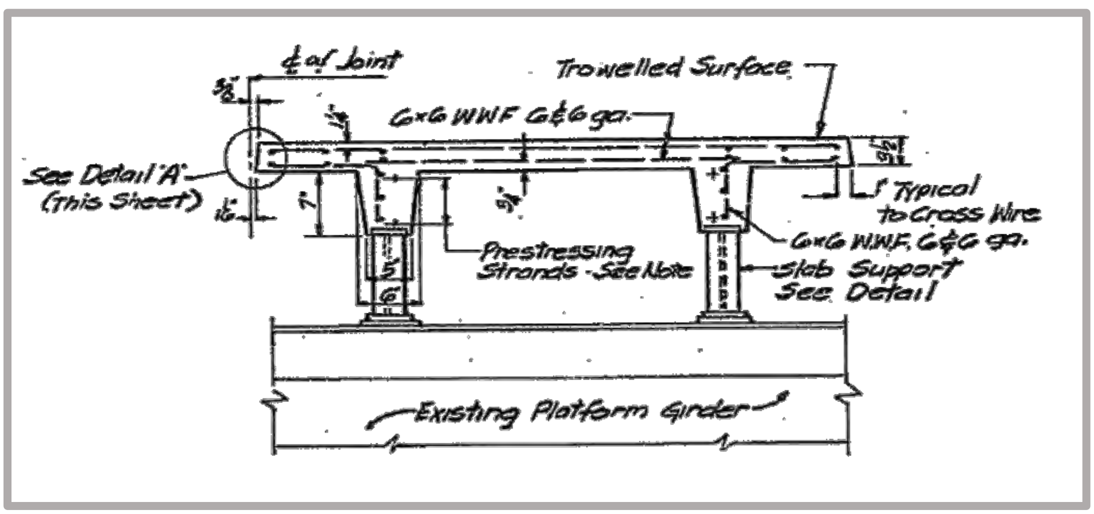

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

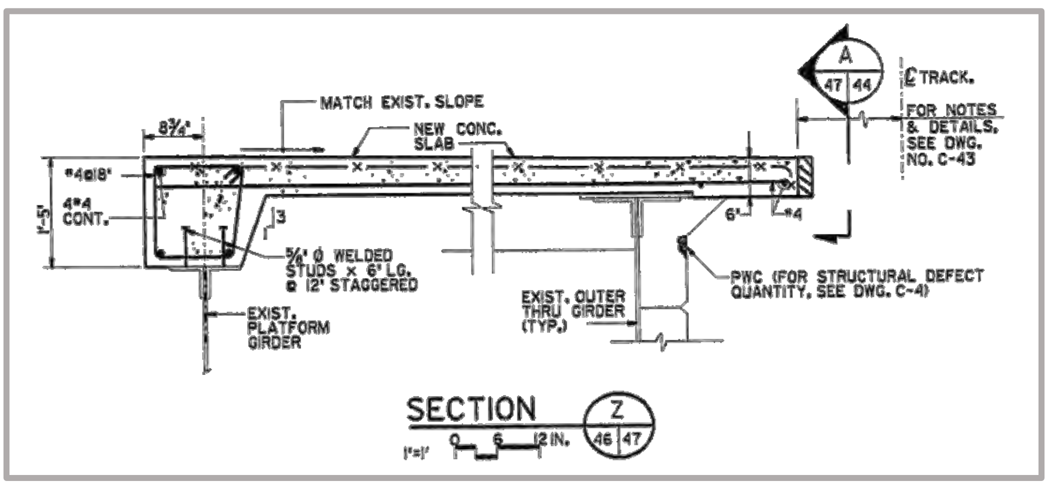

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

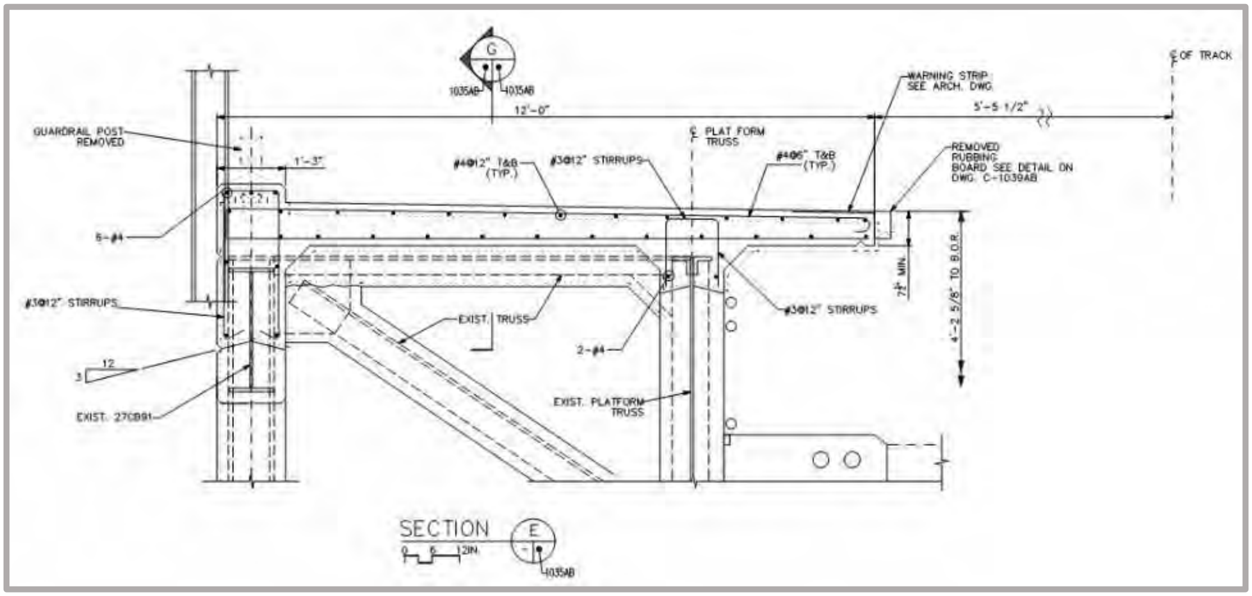

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

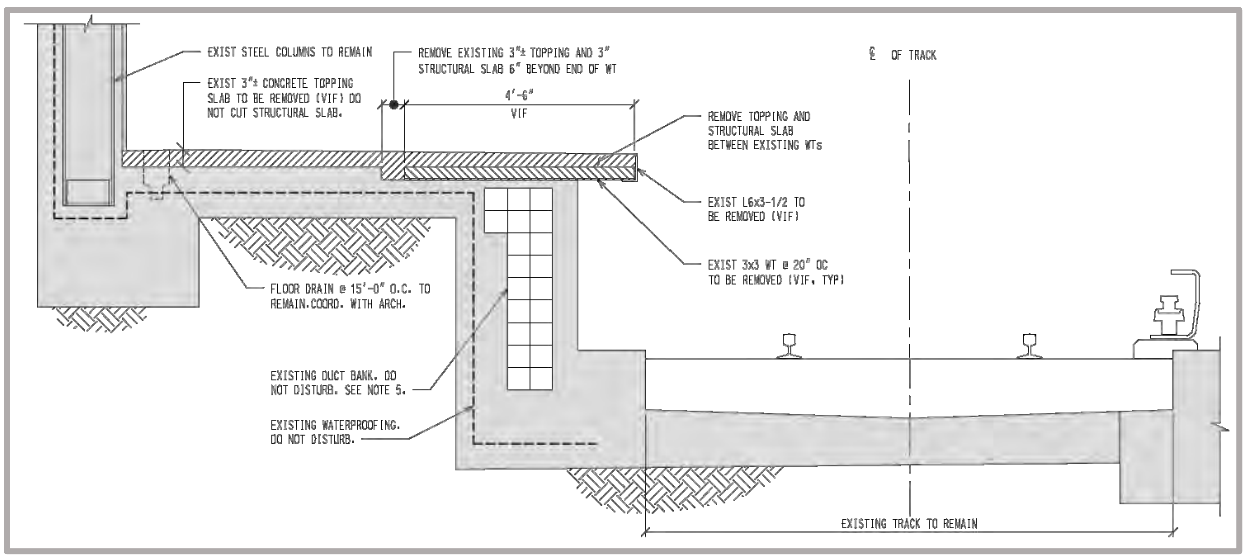

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

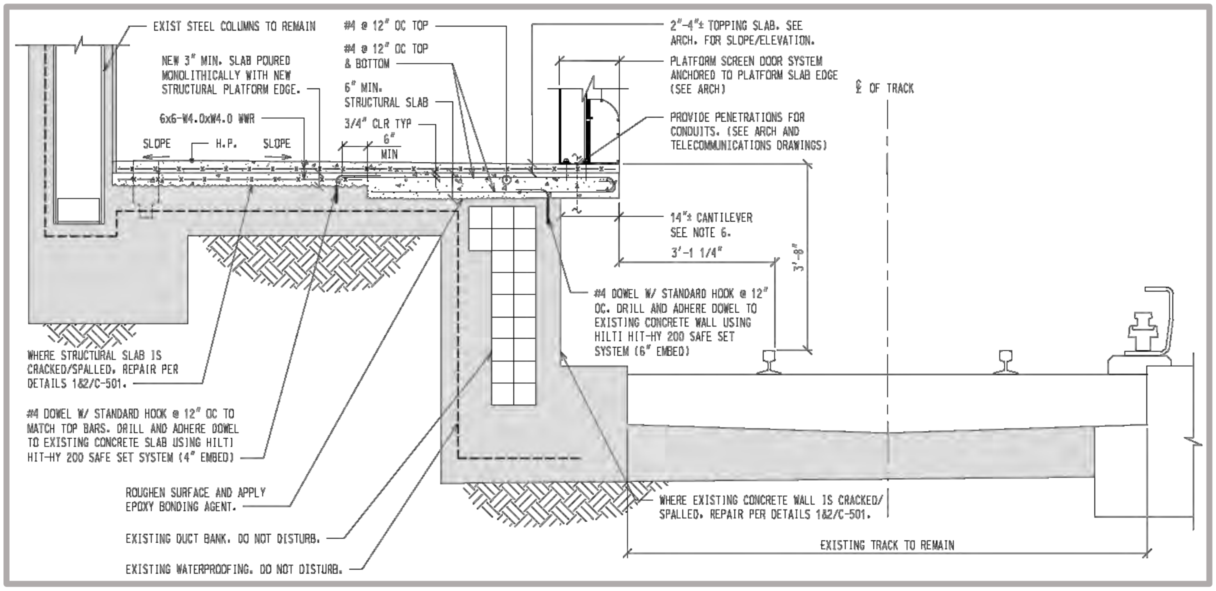

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

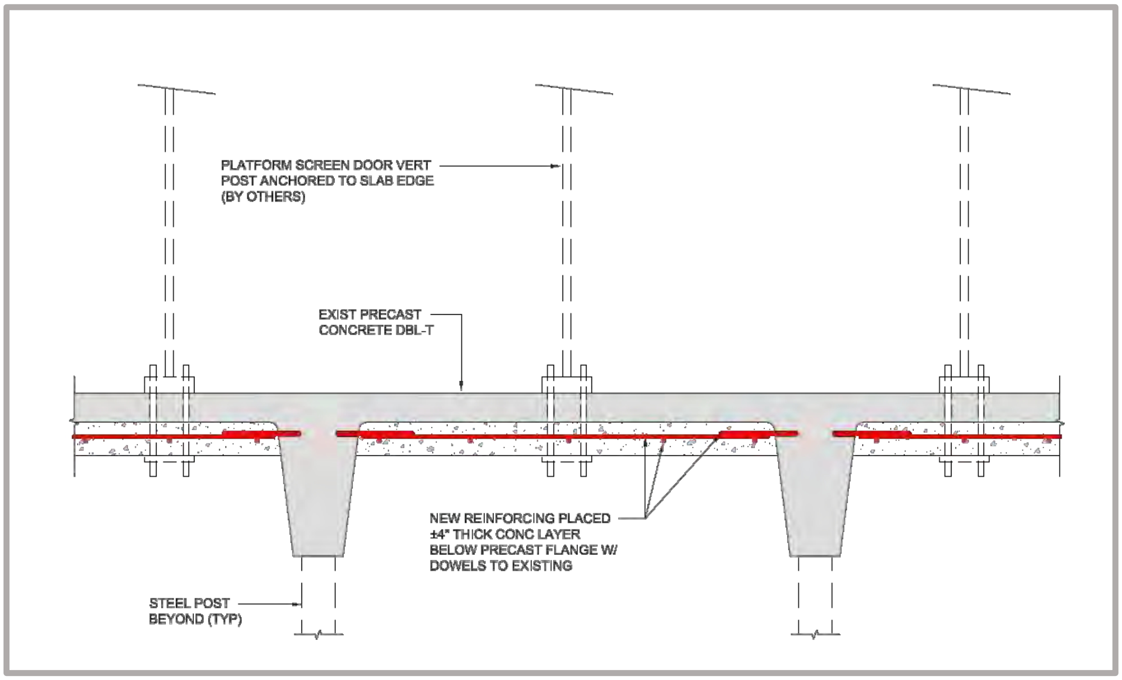

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for J,Z - Line Stations

MTA/NYCT

October 15, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 31 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 8 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for J,Z - Line Stations

MTA/NYCT

October 15, 2018

BASIS OF ESTIMATE

3.0 *Exclusions - Costs not included in the estimate:*

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 *Below the line or “soft” costs:*

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 *Additional Notes*

5.1 Given the limited time available, no drawings were developed to support this estimate.

STATION : CANAL STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	480	LF		
5	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	480	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	960	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	8	CARS		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	960	LF	7	6,720
14	Remove 5' wide section of 3" deep structural slab to platform edge	4,800	SF	12	57,600
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	97	CY	2,500	242,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	962	EA	25	24,050
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	962	EA	25	24,050
19	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
20	Polyethylene edge strip	960	LF	95	91,200
21	Provide sleeves for HV & LV wires	264	EA	110	29,040
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	960	LF	15	14,400
26	Remove existing platform tiles	960	LF	12	11,520
27	Sawcut existing topping concrete at perimeter of removal area	960	LF	5	4,800
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	5,760	SF	8	46,080
29	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	528	SF	8	4,224
30	New Work				
31	New concrete topping to match existing	960	SF	15	14,400

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [BROOKLYN BOUND] =	532	LF		
5	LENGTH OF THE PLATFORM EDGE [QUEENS BOUND] =	532	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,064	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	8	CARS		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction

STATION : JAMAICA CTR. PARSONS / ARCHER

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE LOWER PLATFORM EDGE [NORTH BOUND] =	650	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE [SOUTH BOUND] =	650	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,300	LF		
7	NUMBER OF TRAIN CARS ON THIS LINE =	8	CARS		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,300	LF	7	9,100
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,500	SF	12	78,000
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	131	CY	2,500	327,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,302	EA	25	32,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,302	EA	25	32,550
19	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
20	Polyethylene edge strip	1,300	LF	95	123,500
21	Provide sleeves for HV & LV wires	264	EA	110	29,040
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,300	LF	15	19,500

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'L' (CANARSIE) LINE STATIONS

CONTRACT #: C-32514 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: JULY 9, 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C
- A study of the four Manhattan stations of the Canarsie L-line performed in 2017 in an effort to identify a station to serve as a pilot for the PSD program: Appendix D.

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations.

The Tier 1 analysis of door arrangement in the vehicles dedicated to this line found that there are no problems of incompatibility; one train car type (R143 and R160- dimensionally identical) and one train consist will be run on the Canarsie line for the foreseeable future (the assumed design year for this study is between 2018 and 2032). In addition, this is the first line in the NYCT system to receive computer based train control (CBTC) enabling the stop location of the trains to be consistent. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

There are a total of 24 stations included in this study. Four of them were studied previously to identify the location for the Pilot PSD installation. Of the remaining 19 stations in Brooklyn and 1 in Manhattan, 12 are underground stations, 5 are elevated stations, 2 are at-grade and one is mixed with one subway track and one track at-grade. The stations are a mix of center/island and side platforms thus this report gives a good sense of the variety of issues we are likely to encounter as we complete our study in the rest of the NYCT system.

Of these 20 newly evaluated stations, ten have been found to be not suitable for the installation of PSDs. The reasons for this finding vary but are generally related to space constraints and existing structure.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems]

The following summarizes the major findings:

- ADA clearance issues; the platform edge barriers are 15" thick. Where an existing object (wall, stair, railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle), it is declared infeasible.
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 30') or two smaller rooms (7'-6" x 16'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis within the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.

- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the wall and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

The table on the following page summarizes these findings, and shows that platform edge barriers are feasible at 58% of the "L" (Canarsie) Line stations. Total implementation cost would be $384.2M for APGs and $487.8M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 for the first three years of maintenance, (see Appendix F) therefore for the 14 feasible stations, the aggregate annual maintenance cost would be $13,034,000.

'L' (Canarsie) Line Summary of Feasibility (58% feasible; 14/ 24)

No.	Station Name	Station Type	Platform Type	Feasible Yes / No	Issues / Reason for Failure	Cost APGs	Cost PSDs
MR-115	8th Ave	Subway	Center/Island	Yes		$27.9M	$35.0M

					Total Estimated Cost	$384.2M	$487.8M

*See previous report for Manhattan Stations (Appendix D)

1.0 Station Assessments

1.1 Bedford Avenue Station

Summary: *Bedford Avenue Station (MR-120) is not feasible for both APGs and PSDs as there is not enough area to adequately locate a PSD equipment room(s). Possible equipment room locations on the platform are precluded by minimal platform length beyond the trains' stopping locations and the end of the platform. Additionally, the mezzanines are compact and fully occupied by back-of-house elements and circulation space. If a platform edge barrier (15") and an equipment room (7'-6" wide) were installed along the platform, ADA minimum clearances of 32" would not be met (see figure 1).*

Description:

The Bedford Avenue station is a below-grade station, which has a 20'-wide center/island platform configuration with a cast-in-place concrete platform structure. As part of the Canarsie Tunnel reconstruction project, the planned work at Bedford Avenue Station will renovate the existing station. As part of the planned work, an elevator is being installed. Existing stair replacement as well as additional staircases are also a part of the planned station work. The planned work will also reconfigure portions of the far ends of the platform to optimize space utilization for maintainer and operations areas. The platform will retain its straight geometry with two rows of columns symmetrically placed approximately 15 feet apart on center and 3'-6" from face of columns to the platform edge.

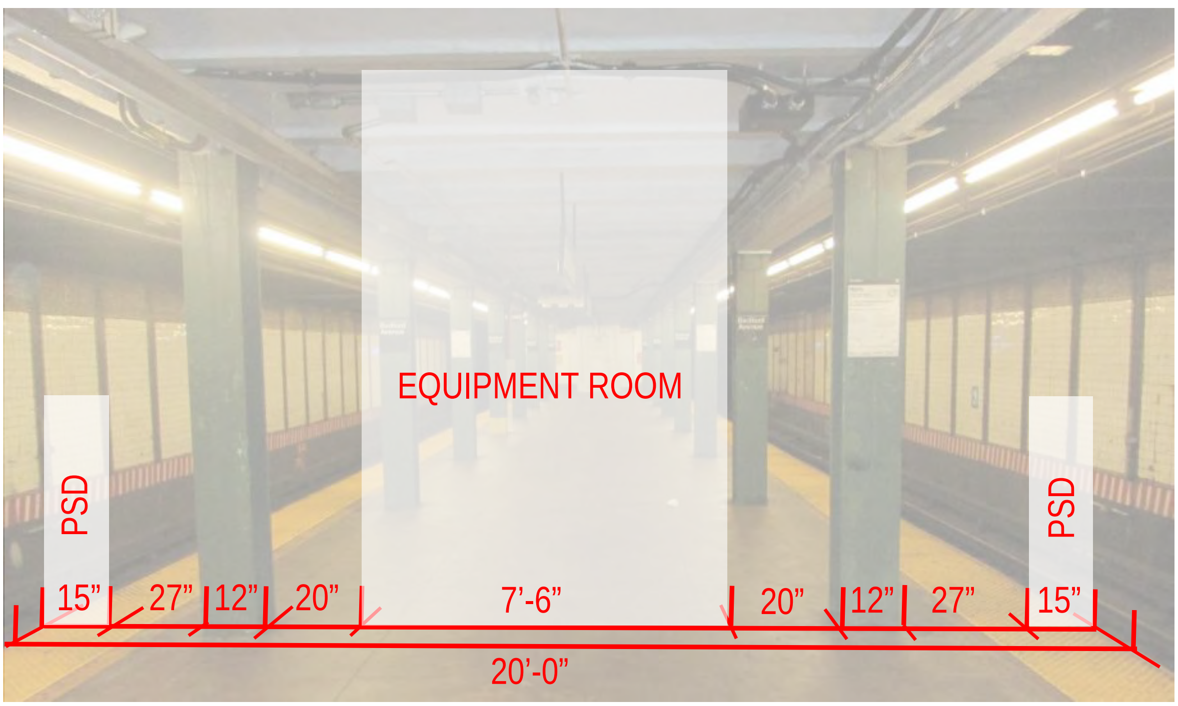

Figure 1 – Platform width analysis, ADA clearance (32") not met– Bedford Avenue Station

1.2 Lorimer Street Station

Summary: Lorimer Street Station (MR-121) is not feasible for APGs or PSDs as there is not enough area to adequately locate PSD equipment room(s). Neither the mezzanine, nor the platforms offer adequate area to accommodate an equipment room. The plan diagram below demonstrates the infeasibility of an equipment room at the end of the platform due to ADA non-compliance at the first door of the train and the infringement on circulation at this end of the station.

Description:
The Lorimer Street Station is a below-grade station consisting of two (2) side platforms with columns at approximately 15 feet on center along the length of the platforms. The platforms have a slightly curved geometry with a single line of columns with a varying offset from the platform edge. At the east-end of the platform (on both tracks) there are existing mechanical rooms and very limited space before the end-of-train position. Connections to other lines are available at the west-end of the station. These areas are highly trafficked in addition to not having adequate area to accommodate an equipment room. As illustrated in figure 1 below, circulation space would be severely reduced in a highly trafficked area.

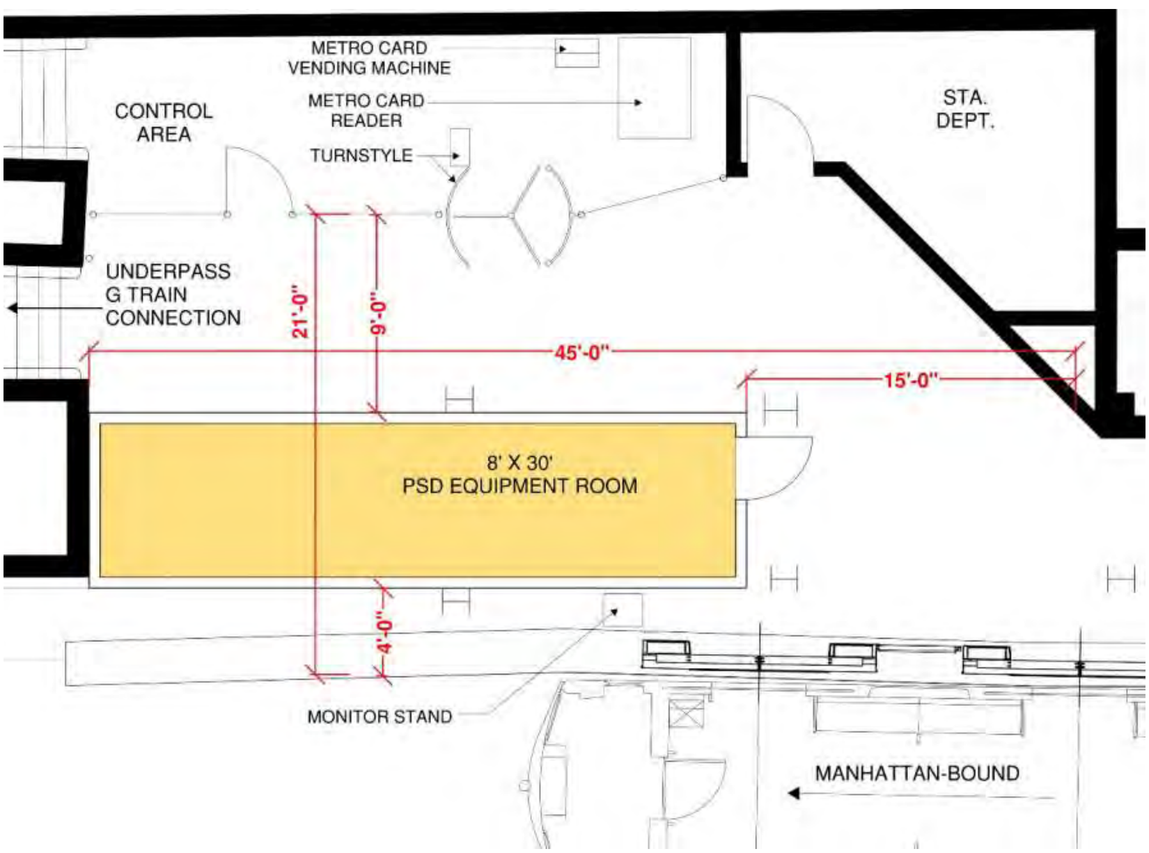

Figure 1– Potential location for equipment room would impede on circulation space- Lorimer Street Station

1.3 Graham Avenue Station

Summary: Graham Avenue Station (MR-122) is feasible for both APGs and PSDs. As there are no columns along the length of the station, there are no ADA obstructions. However, there are various lighting fixtures and conduits above the platform edge and conduit below the platform edge that would need to be coordinated in the installation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.

Description

Graham Avenue Station is a below-grade station with straight side platforms. The platform structure is made of cast-in-place concrete. Platforms are accessed at the center. Back-of-house rooms are located at either end of the platforms. The length of the platforms are column free. Both platforms are approximately 9'-10" wide. Above both platform edges are multiple beam-mounted conduits (approx. 5 above each edge). See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

Two equipment rooms would be required; both rooms can be located at the east end on each platform. Both PSD equipment rooms would be approximately 7'-0" x 17'-0" (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5.

Table of Contents

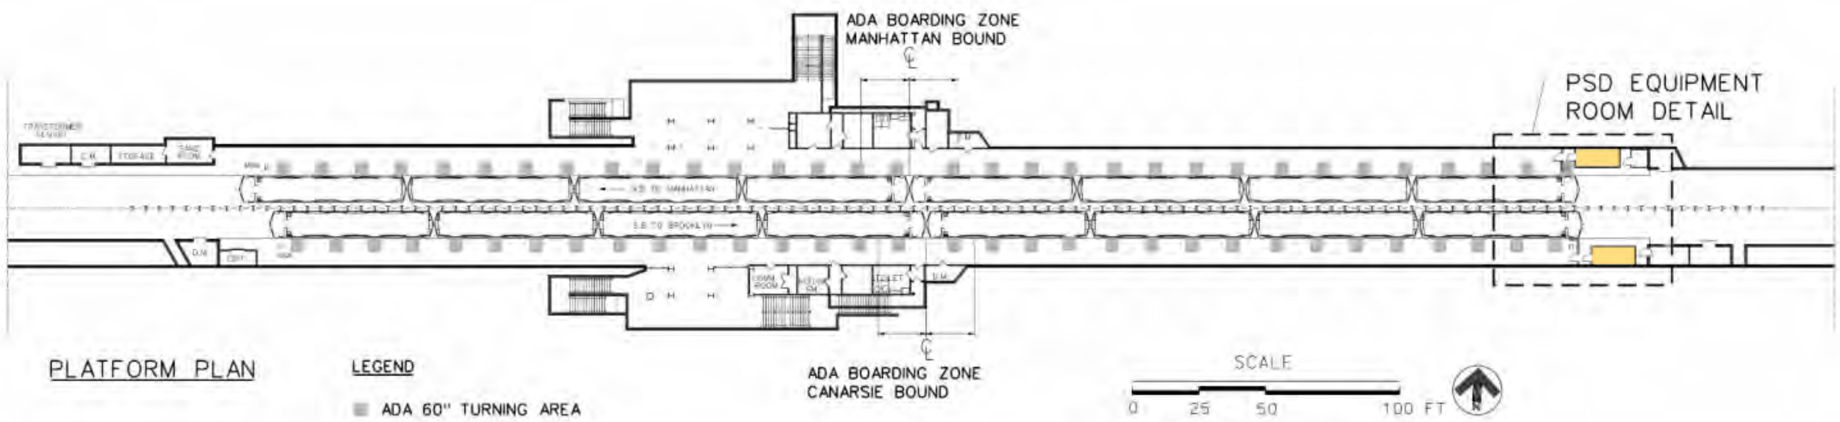

Figure 1 - Station Plan – Graham Avenue Station

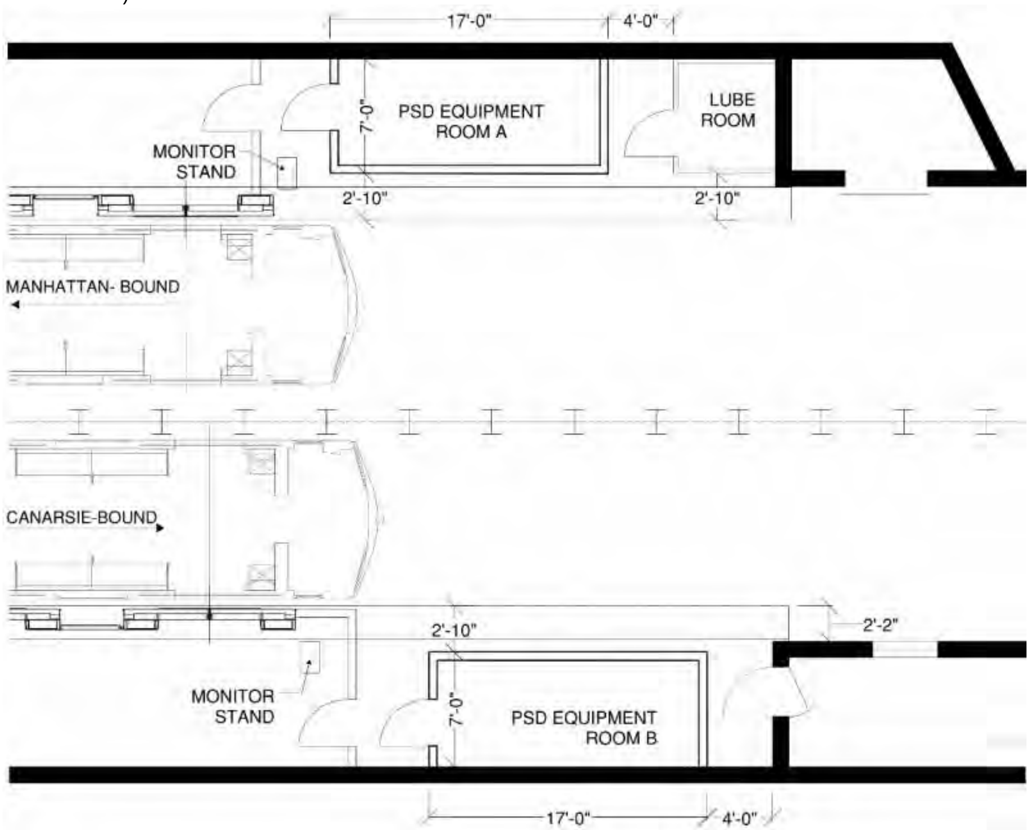

Figure 2 – Enlarged PSD Equipment Room(s) Detail- Graham Avenue Station

Platform obstructions within 5' of edge:

Canarsie-bound: There are no obstructions.

Manhattan-bound: There are no obstructions.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	122
Station Name	Graham Avenue
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	43.8
Peak Demand Load, Max Current (A)	152.0
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	317.0
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	83.0
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.7M to install APGs $36.1 to install PSDs (see Appendix E).

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn
(Graham Avenue Station)

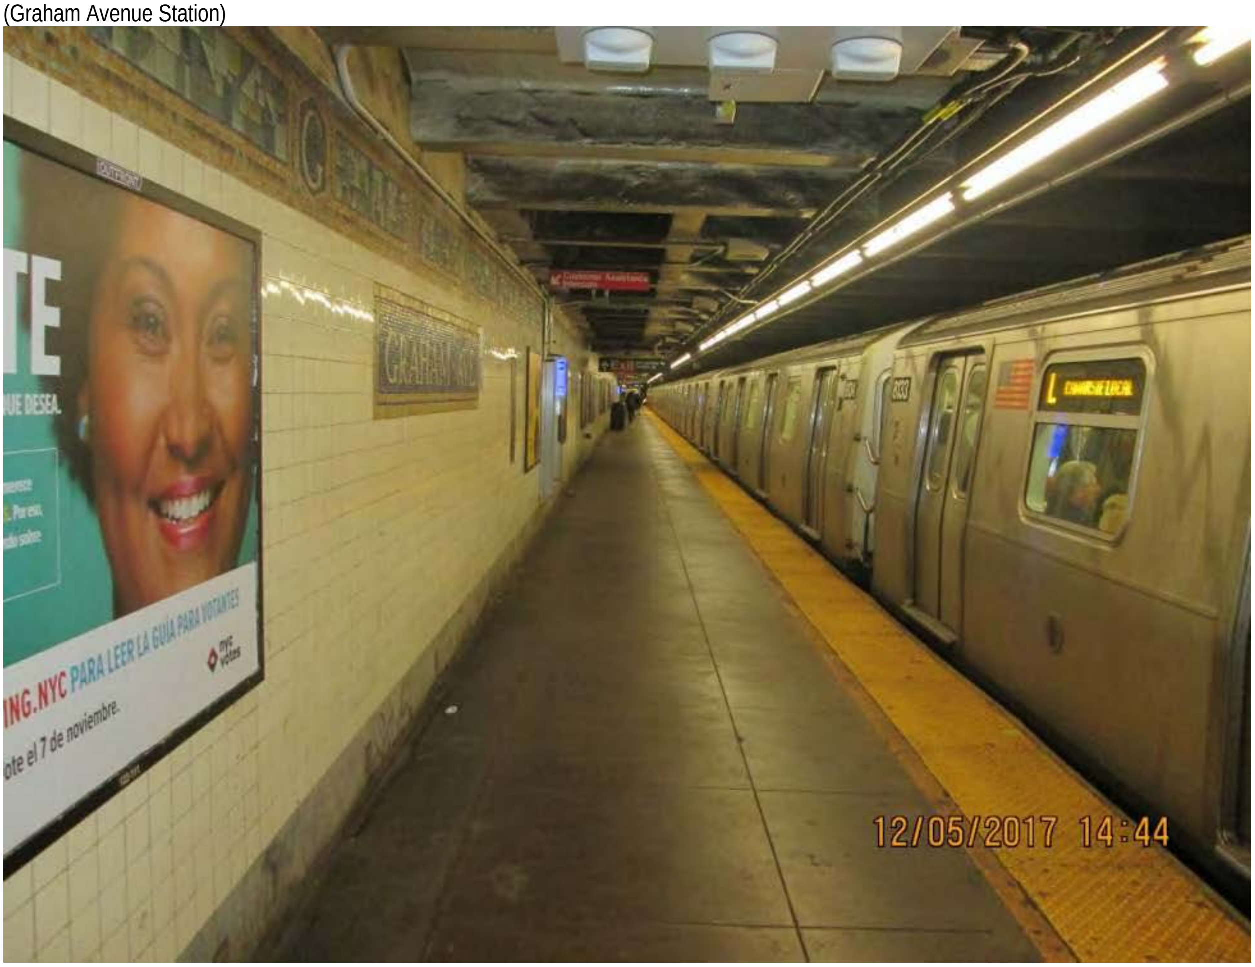

Figure 3 –Typical Platform Condition- Graham Avenue Station

1.4 Grand Street Station

Summary: *Grand Street Station (MR-123) is feasible for both APGs and PSDs. As there are no columns along the length of the station, there are no ADA obstructions. However, there are various lighting fixtures and conduits above the platform edge and conduit below the platform edge that would need to be coordinated in the installation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.*

Description

Grand Street Station is a below-grade station with column free side platforms that are curved. The platform structure is made of cast-in-place concrete. The platforms are accessed at the center. Back-of-house elements are at either end of the platforms as well as adjacent to the central entry areas. The Manhattan-bound platform is approximately 10"-0" wide while the Canarsie-bound platform is 9'-10" wide. There are 4 beam mounted conduits above the platform edge on the Canarsie-bound platform and seven beam mounted conduits above the platform edge on the Manhattan-bound platform. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system

Equipment Room

Two equipment rooms would be required, both rooms can be located at the north end on each platform. Both platforms would house PSD equipment rooms approximately 7'-0" x 17'-0" (see figure 2).

Track Layout

Track is mildly. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.

Table of Contents

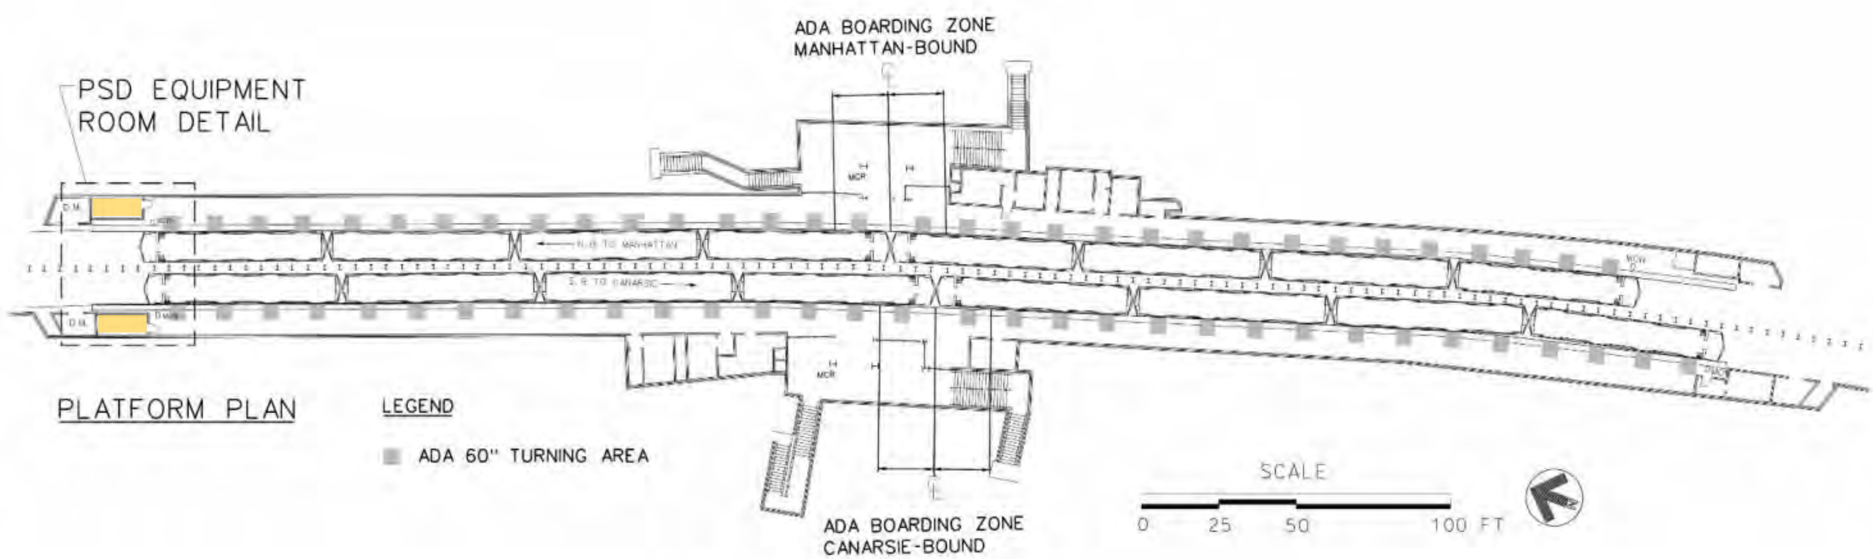

Figure 1 – Station Plan - Grand Street Station

Platform obstructions within 5' of edge:

Canarsie-bound: There are no obstructions.

Manhattan-bound: There are no obstructions.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	123
Station Name	Grand St
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	34.8
Peak Demand Load, Max Current (A)	120.7
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	285.7
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	114.3
Electrical Service is Adequate or Not	Yes

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.7M to install APGs and $36.1M to install PSDs (See Appendix E).

Figure 3 – Typical Platform Condition- Grand Avenue Station

1.5 Montrose Avenue Station

Summary: *Montrose Avenue Station (MR-124) is feasible for both APGs and PSDs. There is an existing column in front of an ADA door on the Canarsie-bound platform which is currently not compliant; this condition would not be exacerbated by the implementation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.*

Description

Montrose Avenue is a below-grade station with side platforms. Both the Manhattan-bound and Canarsie-bound cast-in-place concrete platforms are accessed via a mezzanine at the center of the platform. The platforms are straight with columns located approximately 15' on center. The platforms are 11'-10" wide and column faces are located 42" away from the platform edge. There are minimal back-of-house areas in this station, and they are located at the ends of both platforms. This station is unique in that there are various ceiling heights and column conditions along the platform edge. In some parts of the station, there are angled braces above the platform edge. Ceiling heights at the platform edge vary from 9'-2" to 16'-1". There is minimal conduit above the platform edge. See figure 1 for an overall station plan and figure 4 for a typical platform view.

Full Height PSDs*:* Due to the varying conditions above the platform edge, there would not be a uniform solution for the length of the platform. Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDS (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Conduit hung below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

Two equipment rooms are needed, there is space to accommodate these rooms at the north end of the Canarsie-bound platform and the south end of the Manhattan-bound platform. The room dimensions are approximately 17'-0" x 7'-0" (see figures 2 and 3).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 4.

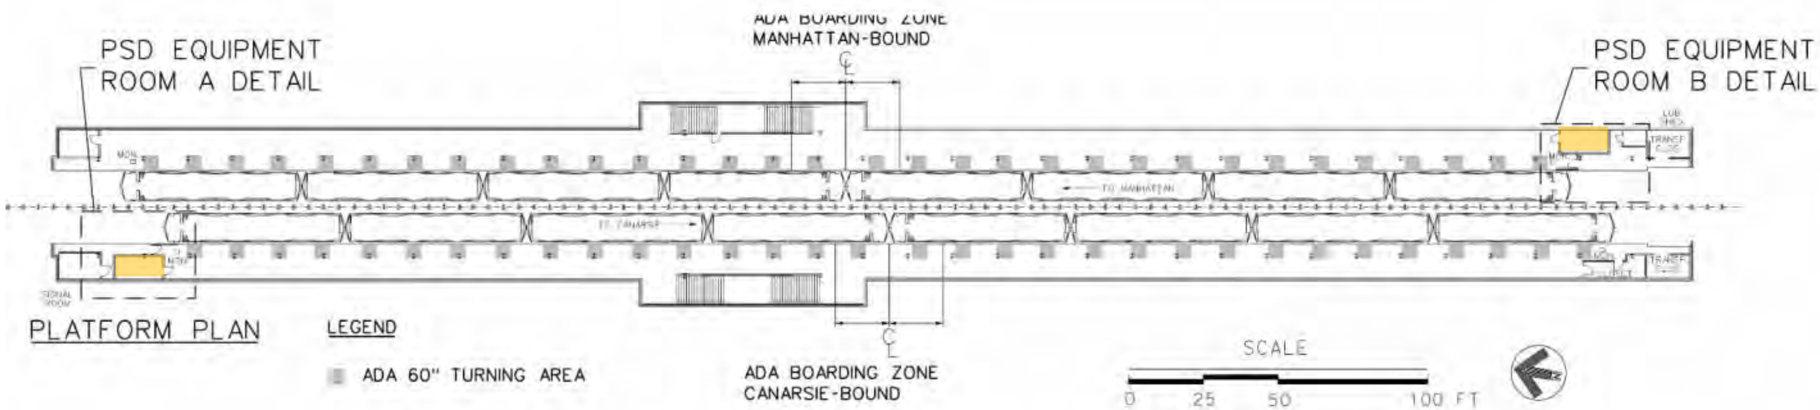

Figure 1– Station Plan – Montrose Avenue Station

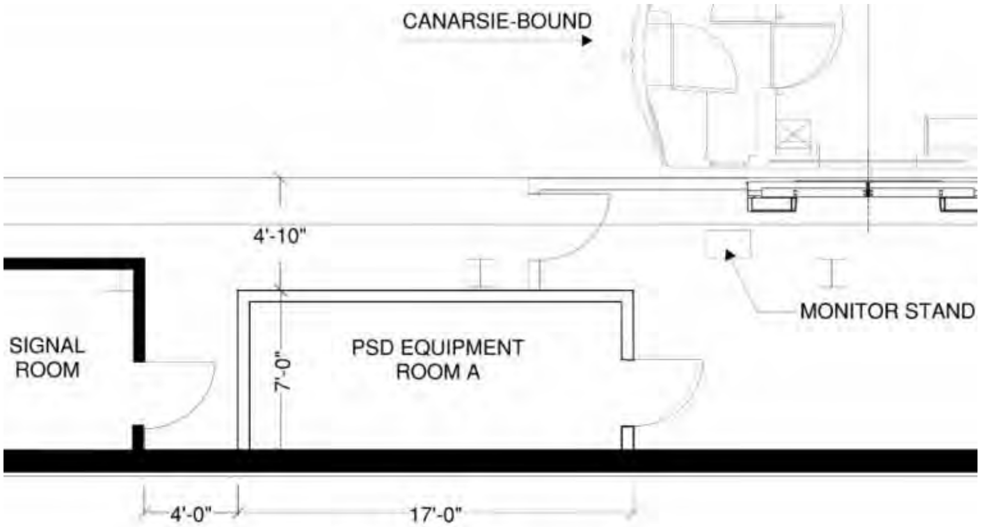

Figure 2 – PSD Equipment Room A Detail- Montrose Avenue Station

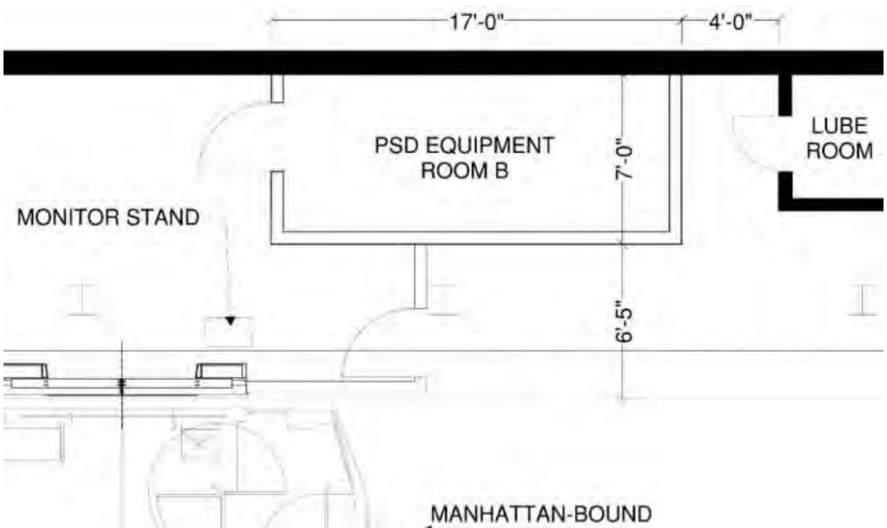

Figure 3 – PSD Equipment Room B Detail- Montrose Avenue Station

Platform obstructions within 5' of edge:

Canarsie-bound: All columns are 42" from platform edge. One column is in front of an ADA - designated door, however the implementation of a platform edge barrier would not exacerbate this already non-compliant condition.

Manhattan-bound: All columns are 42" from platform edge. One column is in front of an ADA - designated door, however, the critical ADA dimensions are met.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	124
Station Name	Montrose Avenue
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	37.2
Peak Demand Load, Max Current (A)	129.1
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	294.1
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	105.9
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough order-of-magnitude cost estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.0M to install APGs $35.4M to install PSDs (See Appendix E).

Table of Contents

Figure 4 – Platform edge condition- Montrose Avenue Station

1.6 Morgan Avenue Station

Summary: *Morgan Avenue Station (MR-125) is feasible for APGS or PSDs. On the Manhattan-bound side, the existing position of the ADA door is in front of a column, but the 32" horizontal clearance is met. On the Canarsie-bound platform, there is a 4" wide fire standpipe which runs the length of the platform, with an arm extending beyond the platform edge. The implementation of PSDs would require rerouting of the standpipe. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.*

Description:

The Morgan Avenue Station is a below-grade, side platform station with columns approximately 15 feet on center along the length of the platform. The platform structure is cast-in-place concrete. Stair access is available at the west end of the platform. Ramped walkway access is located at the east end of the station. The columns at this station are larger due to their tile surround. On the Manhattan-bound platform, the majority of columns are at 3 feet from the platform edge in the area that the train stops. On the Canarsie-bound platform, the face of the columns range from 36 to 39 inches from the edge of the platform. Both platforms are approximately 12' wide. There is a condition on the Canarsie-Bound platform in which a 4" fire standpipe runs along the length of the platform with an arm that extends beyond the platform edge at an elevation of 8 feet above the platform. On the Manhattan-bound platform, there are six conduits mounted above the platform edge. On the Canarsie-bound platform there are three conduits above the platform edge, and signage mounted 2'-2" from the edge of the platform. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. In this case, there would also be the need to reroute the fire standpipe which extends over the platform edge (see figure 4)

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system

Equipment Room

Space required for equipment room is available at the west end of the Canarsie-bound platform (rough/approximate size of 8' x 30'). See figure 2.

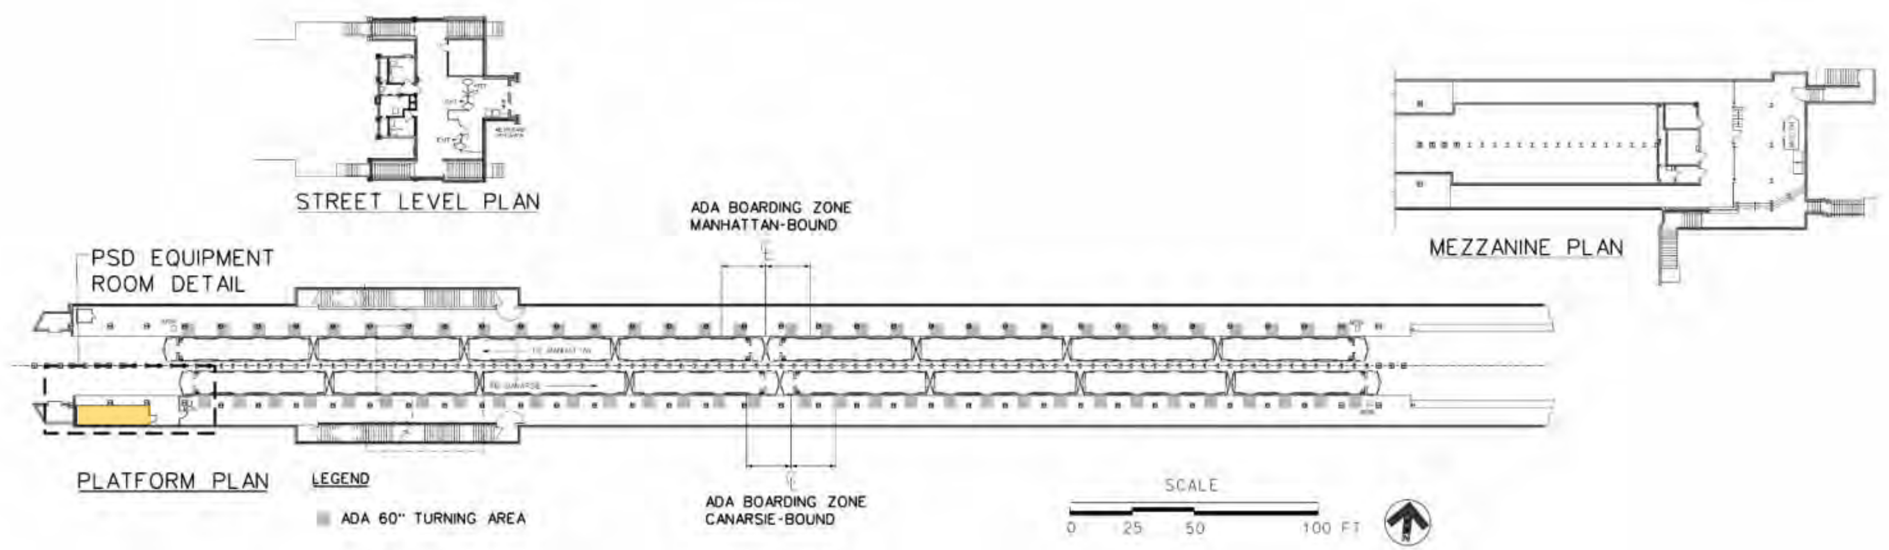

Figure 1– Station Plan – Morgan Avenue Station

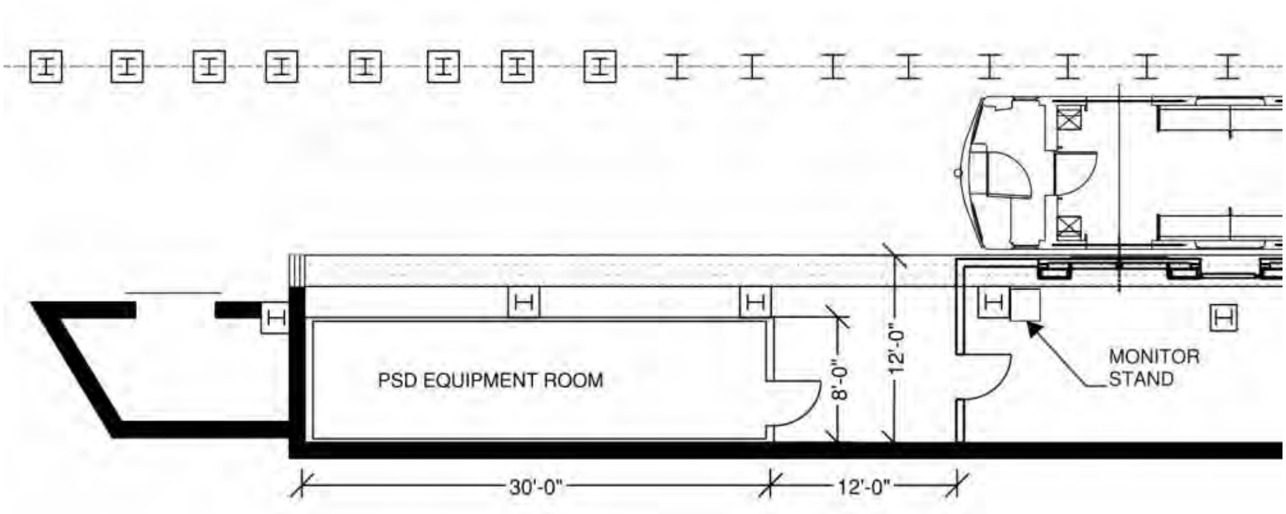

Figure 2 –Enlarged PSD Equipment Room Detail– Morgan Avenue Station

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5.

Platform obstructions within 5' of edge:

Canarsie-bound: Columns range from 36 to 39 inches from the platform edge. There are no other obstructions.

Manhattan-bound: The majority of columns are 3 feet from the platform edge in the area that the train stops. One column is located in front of an ADA - designated door; however, the condition is not exacerbated by the implementation of a platform edge barrier. It is not anticipated that the installation of platform barriers would further impede these existing issues at non ADA-designated doors.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYCT Station MR Number	125
Station Name	Morgan Ave
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	40.2
Peak Demand Load, Max Current (A)	139.5
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	304.5
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	95.5
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.9M to install APGs and $35.3M to install PSDs (See Appendix E).

Figure 3– Typical Platform View – Morgan Avenue Station

Table of Contents

Figure 4 – Canarsie-bound Platform Standpipe Extending Beyond Platform Edge- Morgan Avenue Station

1.7 Jefferson Street Station

Summary: Jefferson Street Station (MR-126) is feasible for both APGs and PSDs. The implementation of PSDs would require rerouting of a standpipe over the Manhattan-bound platform. On the Canarsie-bound platform, there is a column located in front of an ADA-designated door. The current non-complying condition would not exacerbated by the implementation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.

Description

Jefferson Street Station is a below-grade station with straight side platforms. Access is available at both ends of the platform. The platform structure is cast-in-place concrete. The ends of the platforms widen to accommodate stairs and back-of house-elements. Both platforms are approximately 12' wide with columns spaced approximately 15' on center. On both platforms, the faces of the columns are approximately 3'-4" from the platform edge. There is a mezzanine level above the east end of the platform accessed at the intersection of Wyckoff Avenue and Starr Street. On the Manhattan-bound platform, a fire standpipe extends beyond the platform edge with a clearance of 7'-1" to the bottom of the pipe (see figure 4). There is also significant amount of ceiling-mounted conduit at the platform edges. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: As noted in the executive summary, PSDs would require the rerouting of a standpipe. Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Existing wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

One room can be located behind the attendant booth at the mezzanine level at the Starr Street and Wyckoff Avenue intersection. There is only 7'-5" behind the booth, but the length of the equipment room can exceed 30 feet. The proposed room dimension is 7'-0" x 35'-0" (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

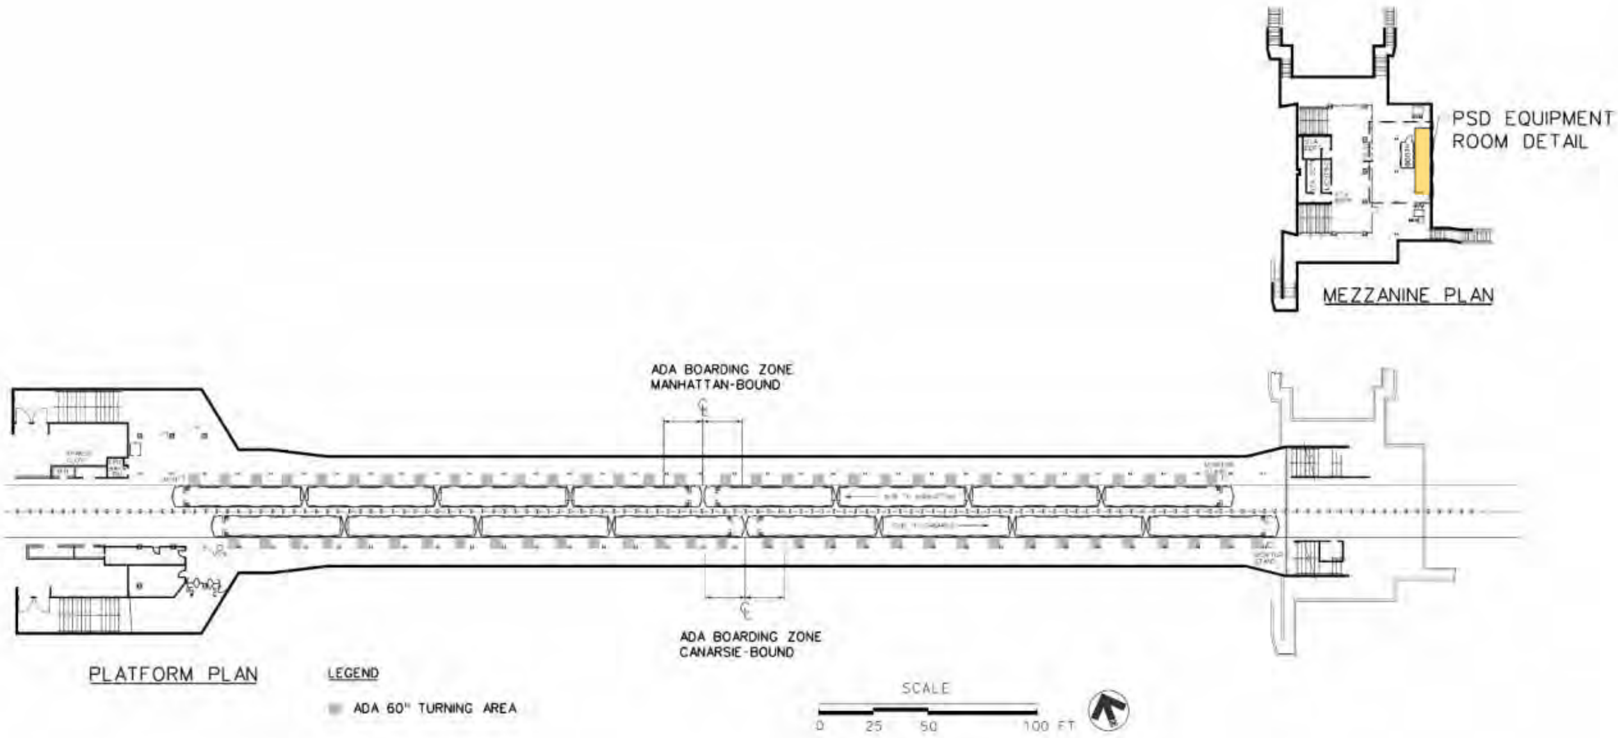

Figure 1 - Station Plan - Jefferson St Station

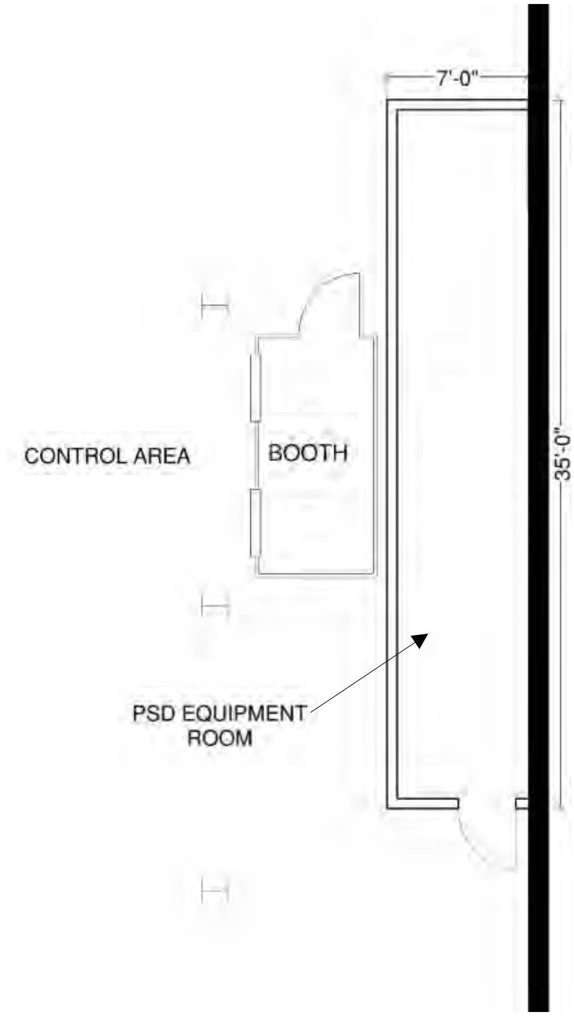

Figure 2 – PSD Equipment Room Detail - Jefferson St Station

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 2.

Platform obstructions within 5' of edge:

Canarsie-bound: All columns are 41" from platform edge. One column is in front of an ADA - designated door; however, the condition is not exacerbated by the implementation of a platform edge barrier.

Manhattan-bound: All columns are 41" from platform edge. There are no other obstructions.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	126
Station Name	Jefferson St
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	34.4
Peak Demand Load, Max Current (A)	119.4
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	284.4
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	115.6
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.1M to install APGs and $35.4M to install PSDs (See Appendix E).

Table of Contents

Figure 3 – Typical platform view- Jefferson St Station

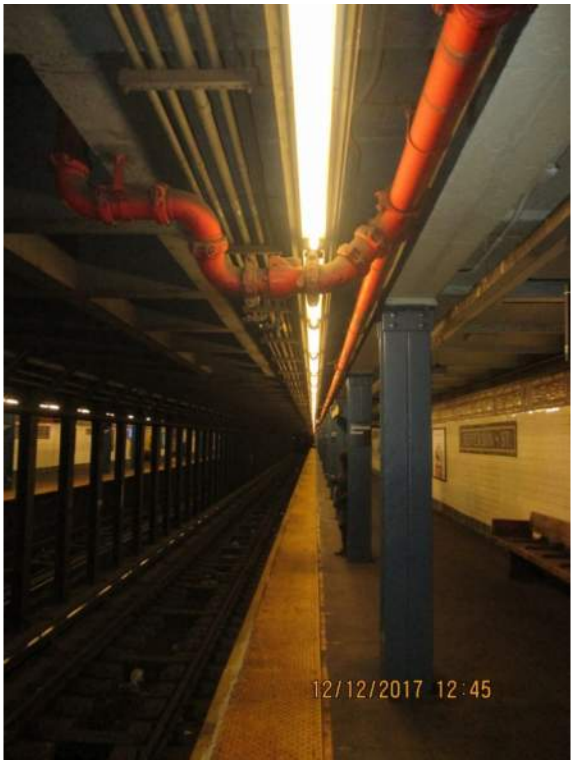

Figure 4 – Fire standpipe extending over platform edge with 7'-1" clearance (Manhattan-bound)—Jefferson St Station

1.8 Dekalb Avenue Station

Summary: Dekalb Avenue Station (MR-127) is feasible for both APGs and PSDs. One column is located in front of an ADA-designated door on the Canarsie-bound platform. The current non-complying condition would not be exacerbated by the implementation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.

Description

Dekalb Avenue is a below-grade station with straight side platforms. The platform structure is cast-in-place concrete. There are entries at both ends of the platforms with a mezzanine entry at the west end of the platform (intersection of Dekalb and Wyckoff). Back-of-house elements are situated at the east-end of both platforms as well as at the mezzanine level. Both platforms are approximately 12' wide with columns spaced approximately 15' on center. The column faces are 3'-5" from the edge of the platform. There is ceiling-mounted conduit above the platform edge. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Existing wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

An 8'-0" x 30'-0" PSD equipment room can be located at the southeast-end of the Manhattan bound platform (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5.

Platform obstructions within 5' of edge:

Canarsie-bound: All columns are 41" from platform edge. One column is located in front of an ADA - designated door; however, the already non-compliant condition is not exacerbated by the implementation of a platform edge barrier.

Manhattan-bound: All columns are 41" from platform edge. There are no other obstructions.

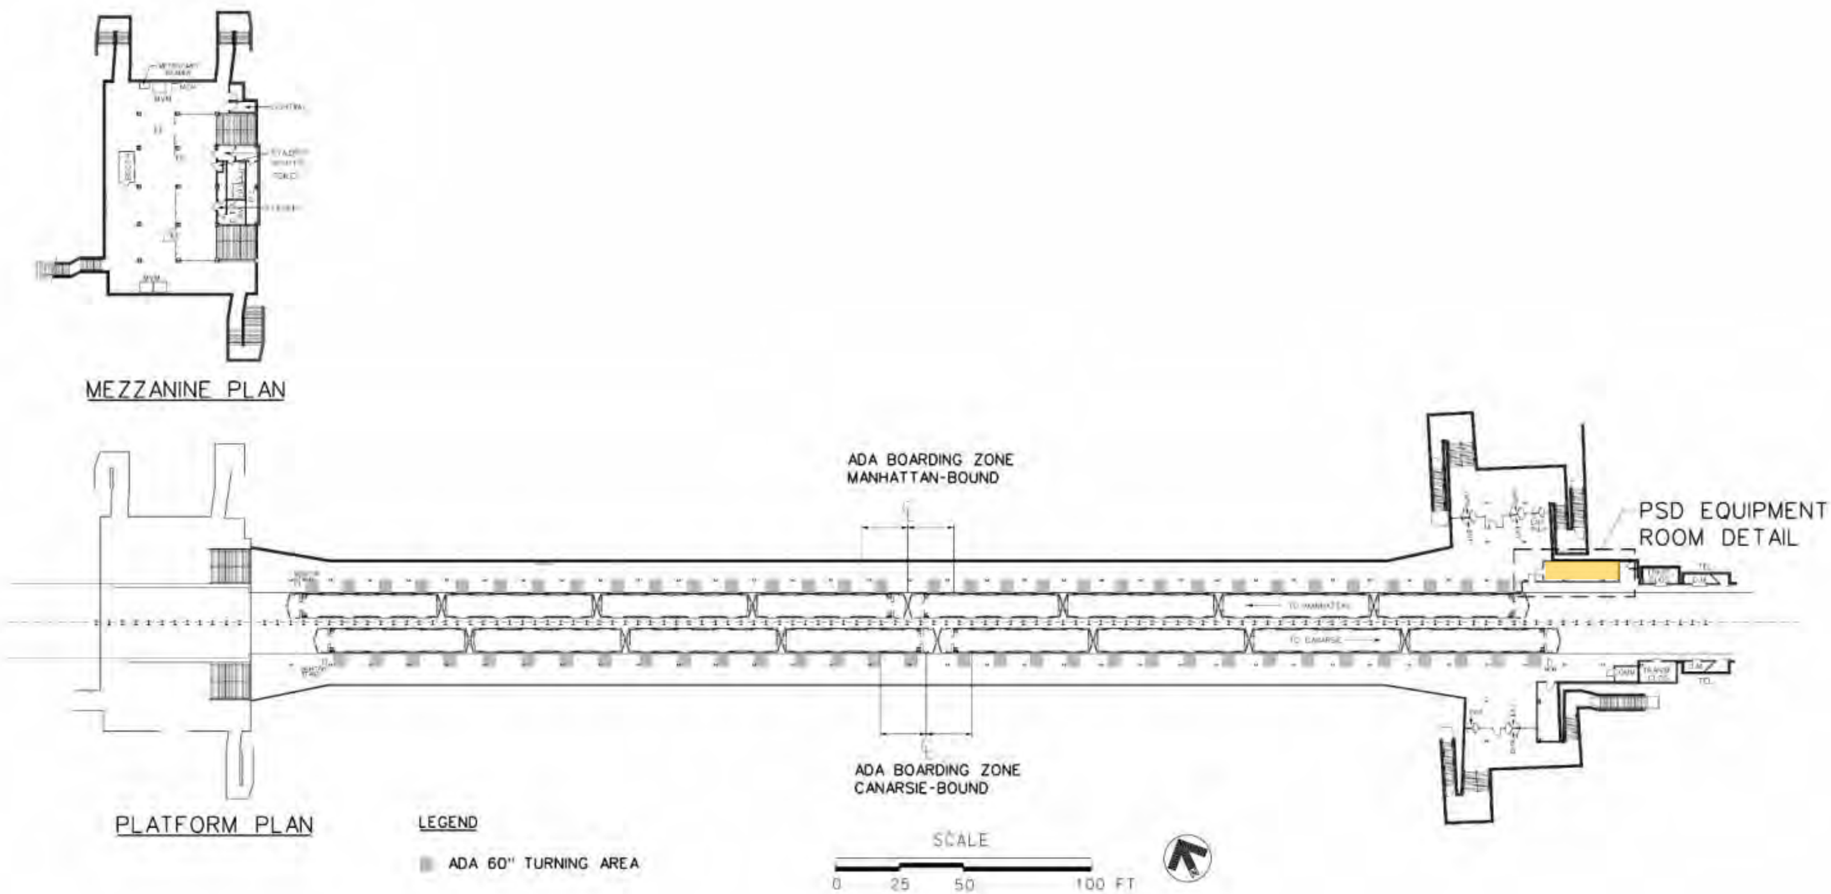

Figure 1 – Station Plan- Dekalb Avenue Station

Table of Contents

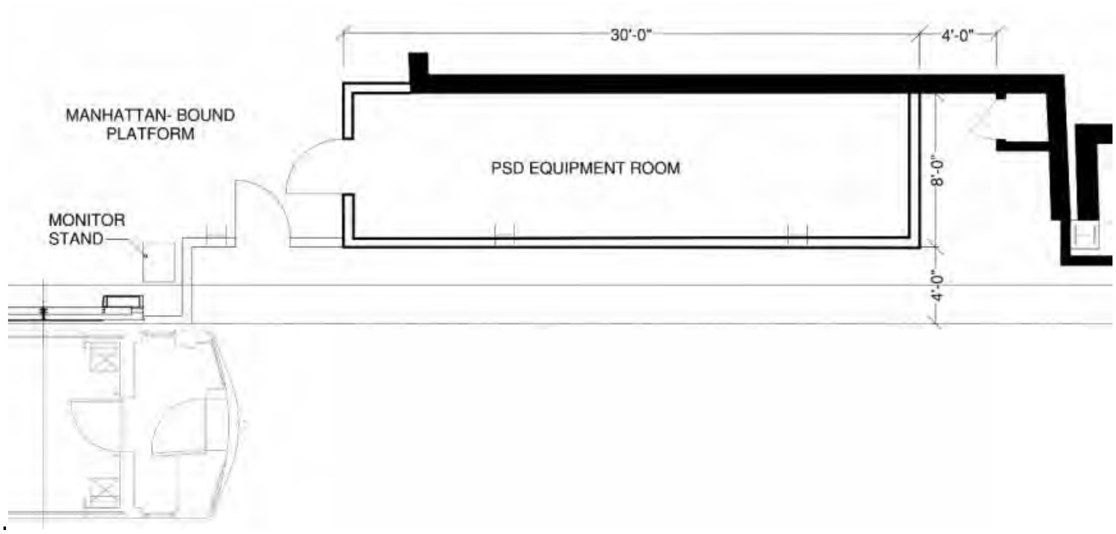

Figure 2 – PSD Equipment Room Detail – Dekalb Avenue Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	127
Station Name	DeKalb Avenue
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	36.6
Peak Demand Load, Max Current (A)	127.0
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	292.0
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	108.0
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.0M to install APGs and $35.4M to install PSDs (See Appendix E).

Figure 3– Typical Platform Edge Condition- Dekalb Avenue Station

1.9 Myrtle Wyckoff Avenue Station

Summary: Myrtle Wyckoff Avenue Station (MR-128) is feasible for both APGs and PSDs. There is a significant amount of conduit at and beyond the Canarsie-bound platform edge which present challenges for the installation of full-height PSDs. In addition, the implementation of full height PSDs will require rerouting of a standpipe over the Canarsie-bound tracks (see figure 3). Existing power is adequate.

Description

Myrtle Wyckoff Avenue Station is below-grade with a straight center/island platform. The platform structure is cast-in-place concrete. Back-of-house elements are located at the tapered ends of the platform. There are four staircases along the length of the platform and a centrally located elevator. The platform width is 19'-4". Columns are spaced approximately 15' on center and are located at the center of the platform. There is conduit above both platform edges, however at the Canarsie-bound side of the platform there is a lot of conduit that would have to be reconfigured. See figure 1 for an overall station plan.

Full Height PSDs: As noted above, full height PSDs would require the rerouting of a standpipe and reconfiguration of conduit. Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Existing wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

A 12'-0" x 16'-0" PSD equipment room can be located at the mezzanine level in the control area (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 2.5.

Obstructions within 5' of edge:

Manhattan-bound: All columns are 4'-11" from the platform edge. There is an existing column in front of one of the ADA designated doors, but the required 60" turning radius is not impacted by this column.

Canarsie-bound: All columns are 4'-11" from the platform edge.

Table of Contents

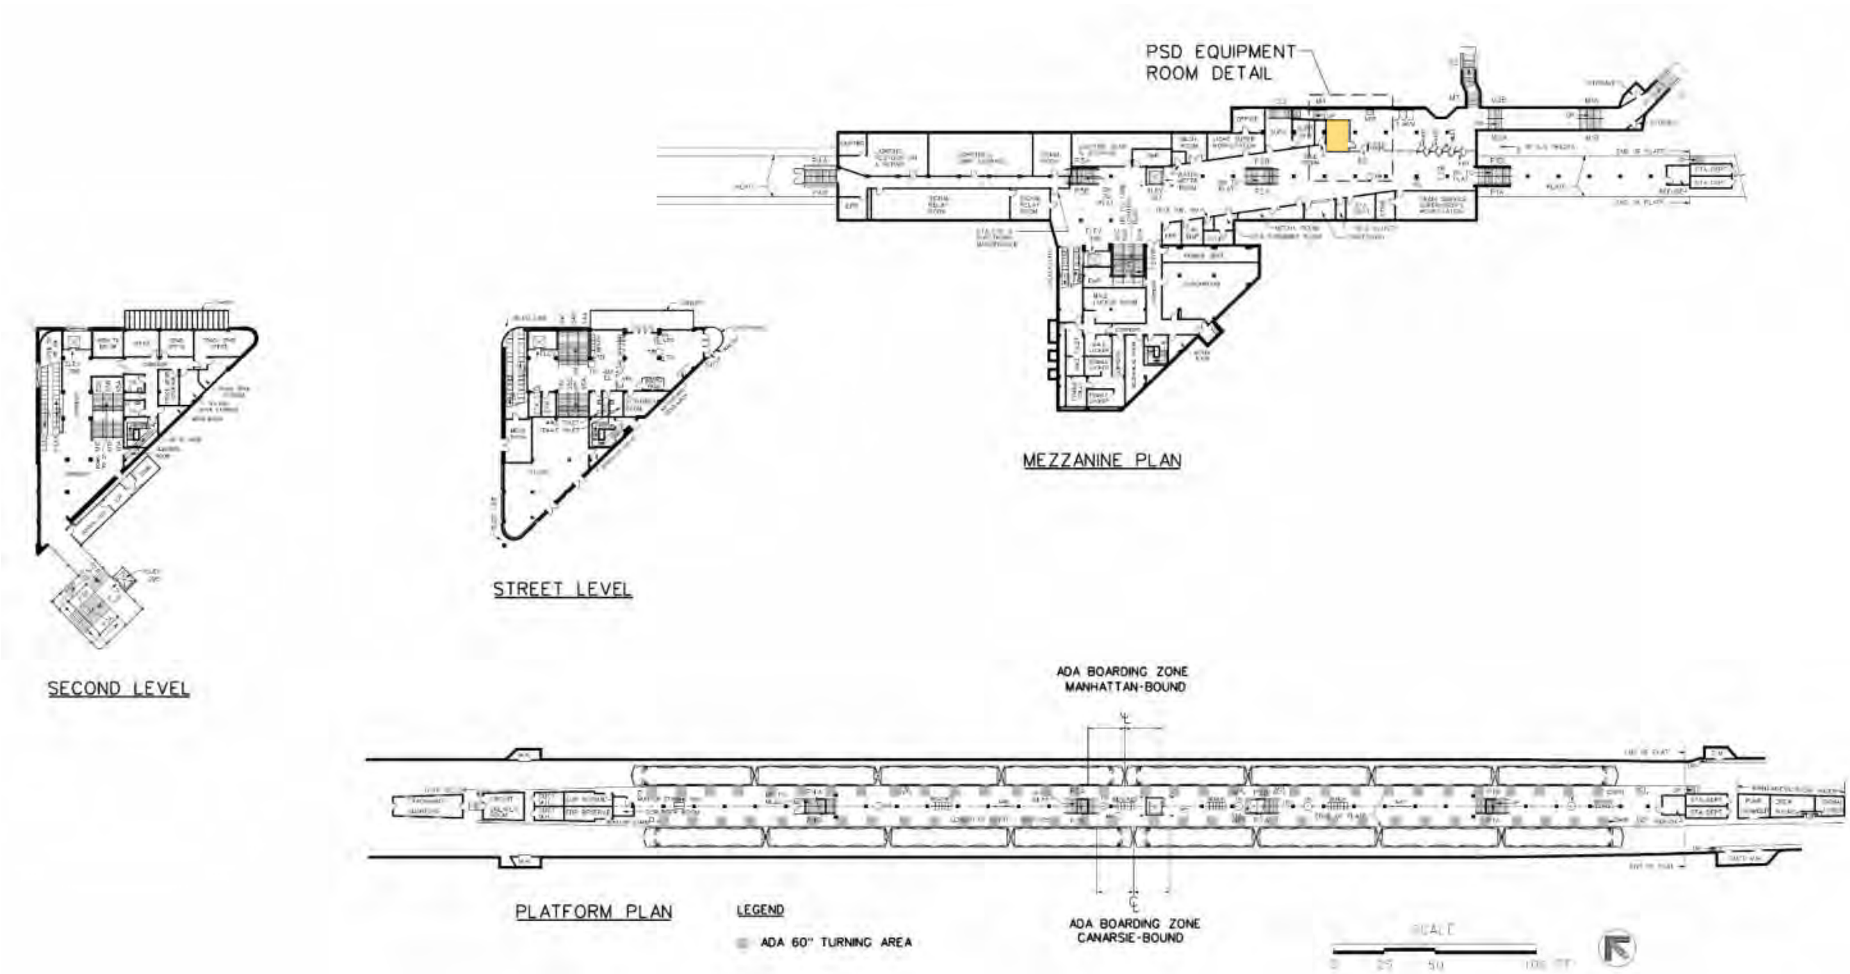

Figure 1 – Station Plan – Myrtle Wyckoff Avenue Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table on the following page. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	128
Station Name	Myrtle Ave–Wyckoff Ave
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	81.6
Peak Demand Load, Max Current (A)	283.1
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	448.1
Station Service Power Capacity, (A)	1200.0
Service Spare Capacity, (A)	751.9
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.9M to install APGs and $35.3M to install PSDs (See Appendix E).

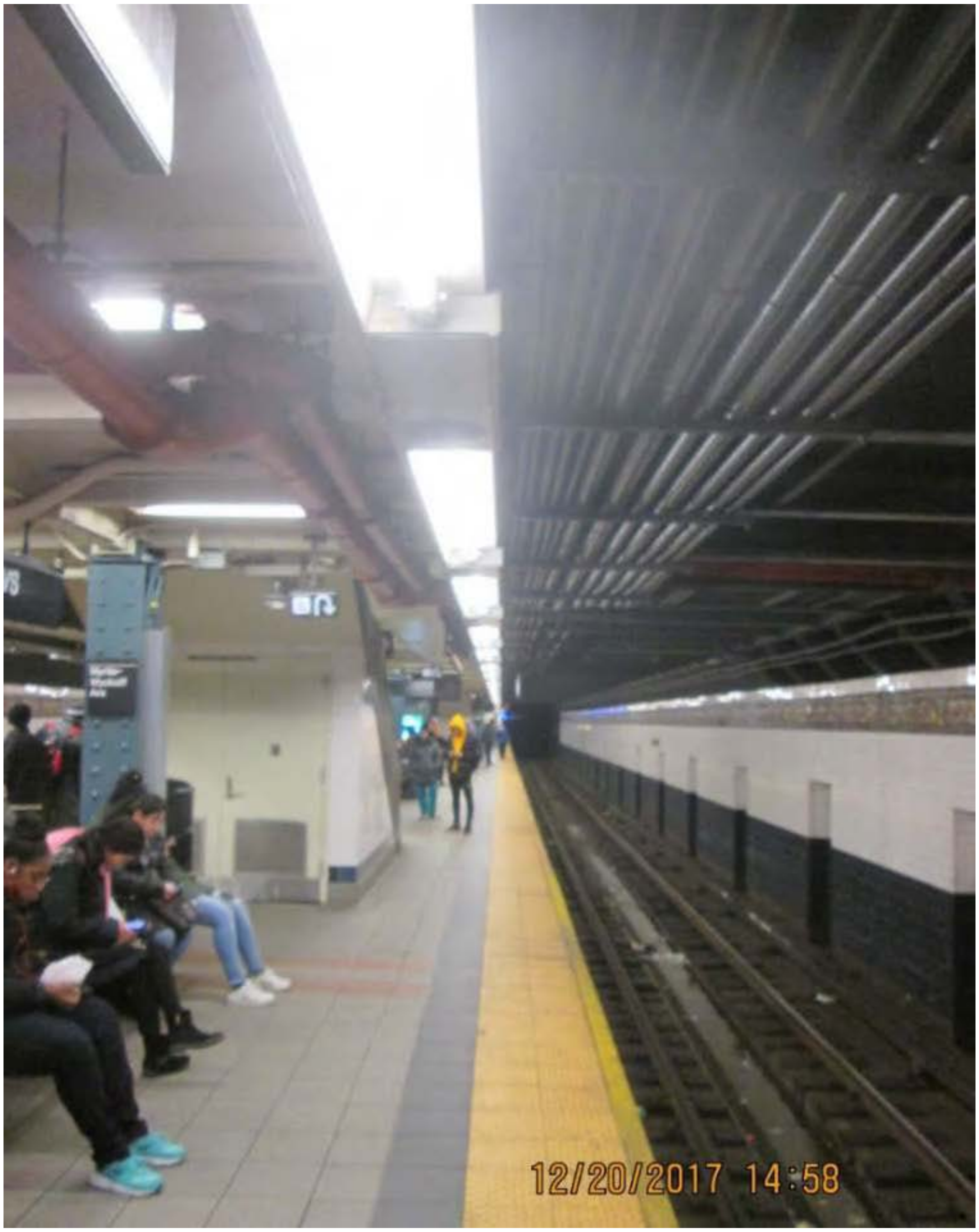

Figure 3 – Canarsie-bound: fire standpipe and conduit at/beyond platform edge– Myrtle Wyckoff Avenue Station

1.10 Halsey Street Station

Summary: *Halsey Street Station (MR-129) is feasible for both APGs and PSDs. On the Canarsie-bound platform, there is a column in front of an ADA-designated door. The current non-compliant condition would not be exacerbated in the implementation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.*

Description:

Halsey Street is a below-grade station with straight side platforms. The platform structure is cast-in-place concrete. Rather than being perfectly in line with each other, the platforms are shifted lengthwise by two subway cars. Both platforms are accessed at their ends. Both platforms are approximately 12' wide with columns spaced approximately 15' on center. Column faces are approximately 3'-4" (40") from the platform edge. There is ceiling-mounted conduit above the platform edge and wall-mounted conduit below the platform edge. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Existing wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

A 12'-0" x 16'-0" equipment room can be accommodated after the pay-gate at the George Street entrance on the Manhattan-bound side of the station (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5.

Platform obstructions within 5' of edge:

Canarsie-bound: All columns are 40" from platform edge. One column is centered on the ADA - designated door; however, the condition is not exacerbated by the implementation of a platform edge barrier.

Manhattan-bound: All columns are 40" from platform edge. There are no other obstructions.

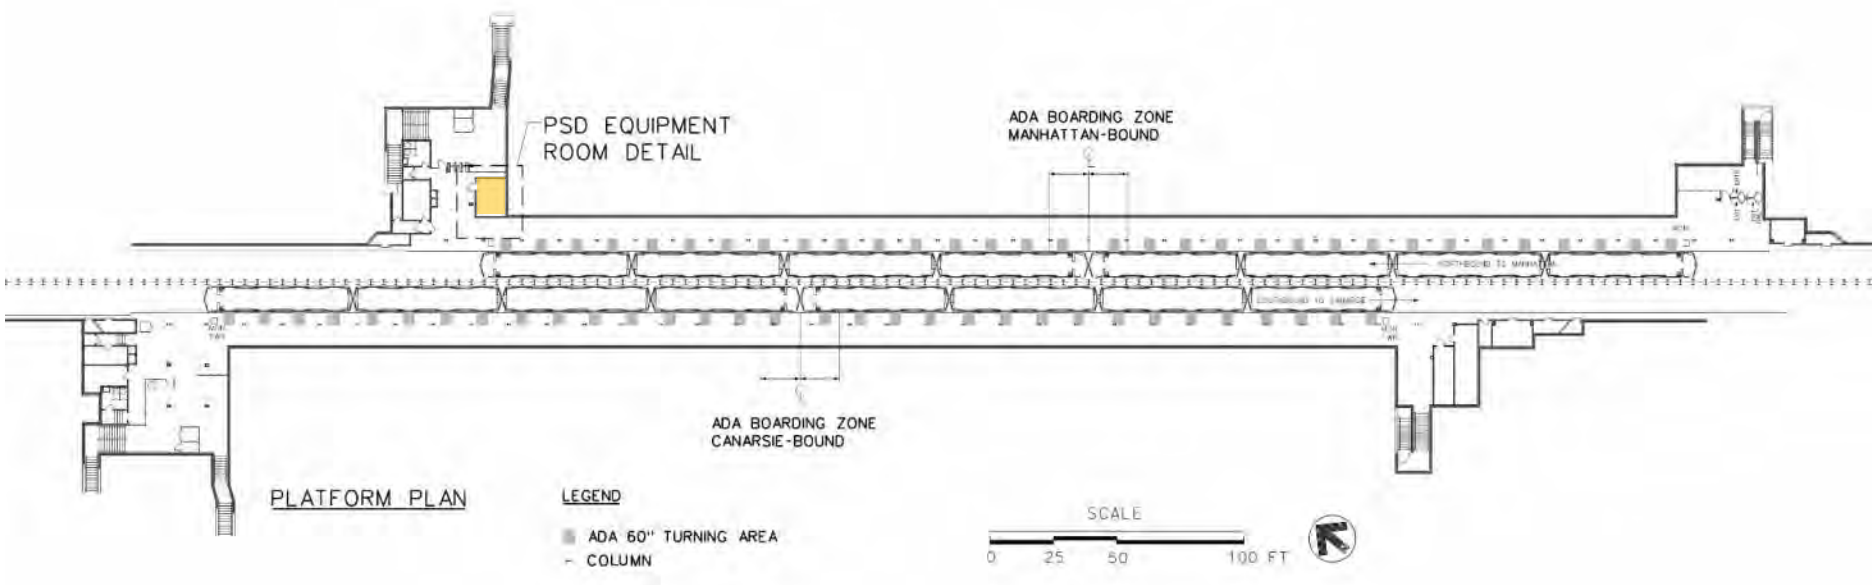

Figure 1 – Station Plan- Halsey St Station

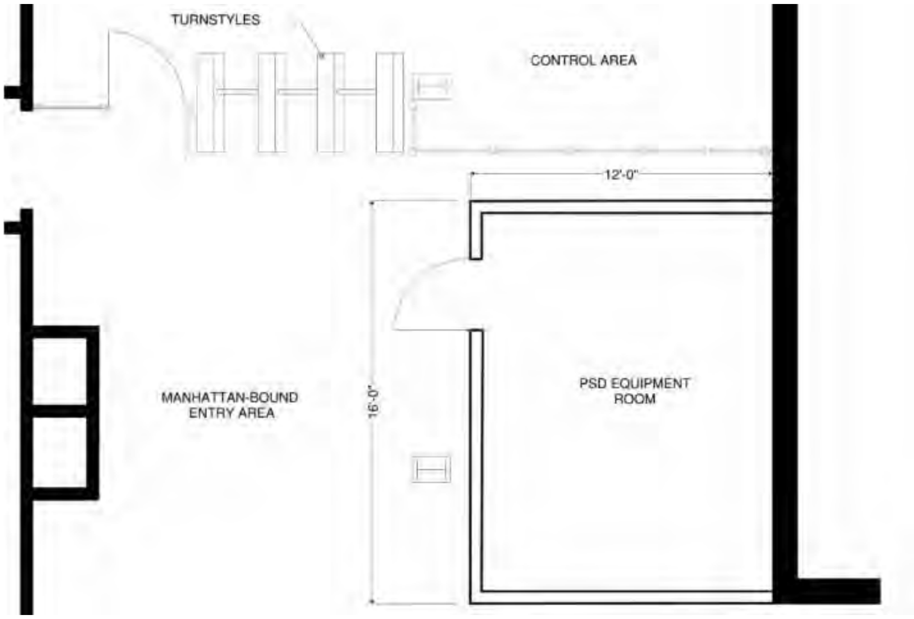

Figure 2 – PSD Equipment Room Detail- Halsey St Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	129
Station Name	Halsey St
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	34.0
Peak Demand Load, Max Current (A)	118.0
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	283.0
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	117.0
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.0M to install APGs and $35.3M to install PSDs (See Appendix E).

Figure 3– Typical Platform View– Halsey St Station

1.11 Wilson Avenue Station

Summary: *Wilson Avenue Station (MR-130) is feasible for both APGs and PSDs. The Wilson Avenue station has one track at-grade (Canarsie-bound) and one track below-grade (Manhattan-bound). To accommodate an equipment room on the Manhattan-bound platform, the stop line needs to be adjusted (moved approximately 6'-6"). In doing so, an existing obstruction at the ADA boarding zone is eliminated. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.*

Description

Wilson Avenue Station is a unique station, unlike any other on the 'L" Line. The Canarsie-bound and Manhattan-bound platforms are stacked on top of one another. The Canarsie-bound platform is at-grade, while the Manhattan-bound platform is below-grade. Both platforms are straight and made of cast-in-place concrete. The Canarsie-bound platform is 12'-10" wide, columns are located against the platform wall and the face of the column is 11'-4" from the edge of the platform. The Manhattan-bound platform is approximately 11'-10" wide, the face of the columns are typically 3'-2" from the platform edge. On both platforms, columns are spaced approximately 15' on center. The canopy of the Canarsie-bound platform extends 1'-6" beyond the platform edge. Hanging from the canopy on the Canarsie-bound platform, is a cable tray located within 2' of the platform edge with a vertical clearance of 8'-2". There is also signage at the platform edge (see Figure 4). The Manhattan-bound platform has seven ceiling-mounted conduits above and beyond the platform edge (see Figure 5). See figure 1 for an overall station plan.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling/canopy as well as reconfiguration of existing ceiling/canopy-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. On the Canarsie-bound platform, there is conduit mounted below the platform edge as well as a large pipe at track-level that runs the length of the platform with smaller pipes running beneath the platform structure. These items would need to be coordinated in the implementation of APGs.

Equipment Room

Two PSD equipment rooms are needed. One room can be located at the north end of both platforms (rough/approximate dimensions: 7' x 16'-6"). To accommodate this room on the Manhattan-bound platform, the stop line would need to be moved by approximately 7 feet. See Figures 2 and 3 for PSD equipment room enlargements (see figures 2 and 3).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

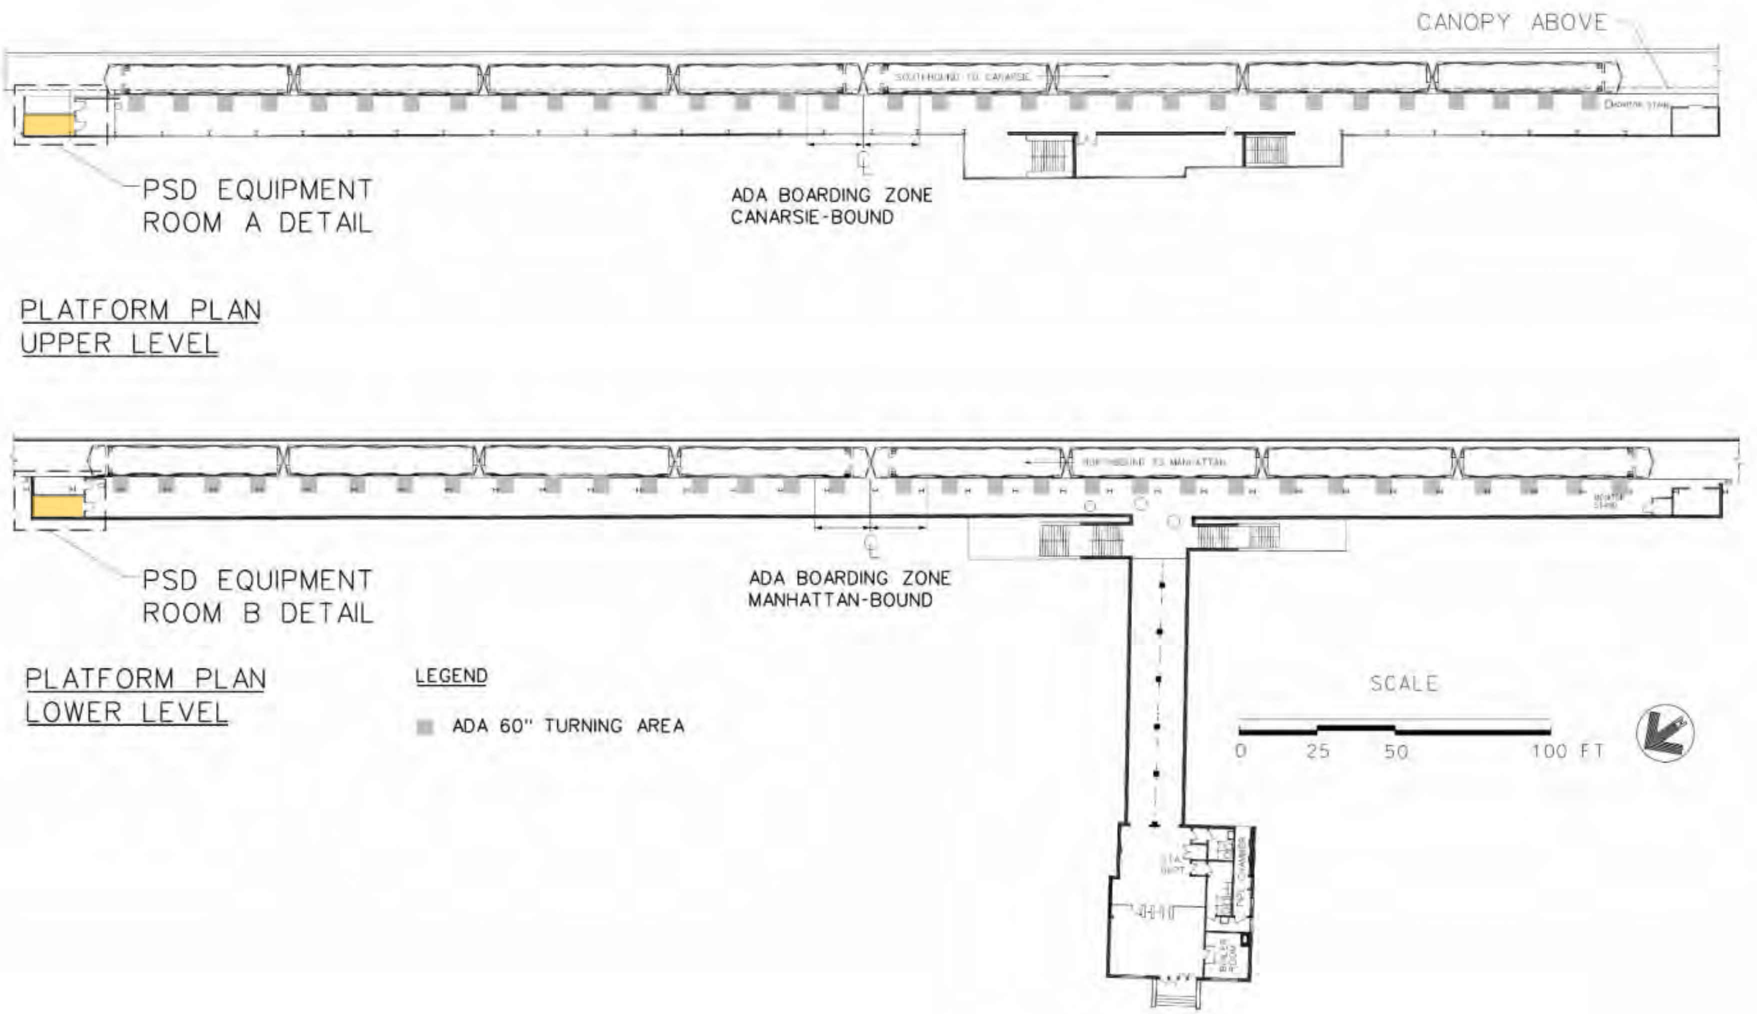

Figure 1- Station Plan – Wilson Avenue Station

Table of Contents

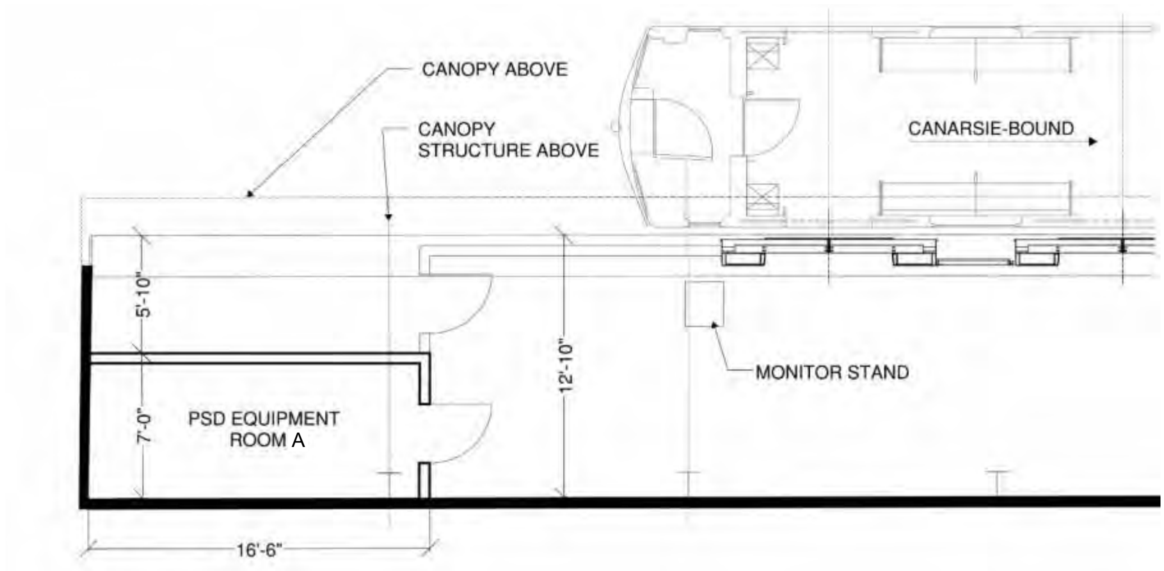

Figure 2 – PSD Equipment Room A Detail (Upper Level) – Wilson Avenue Station

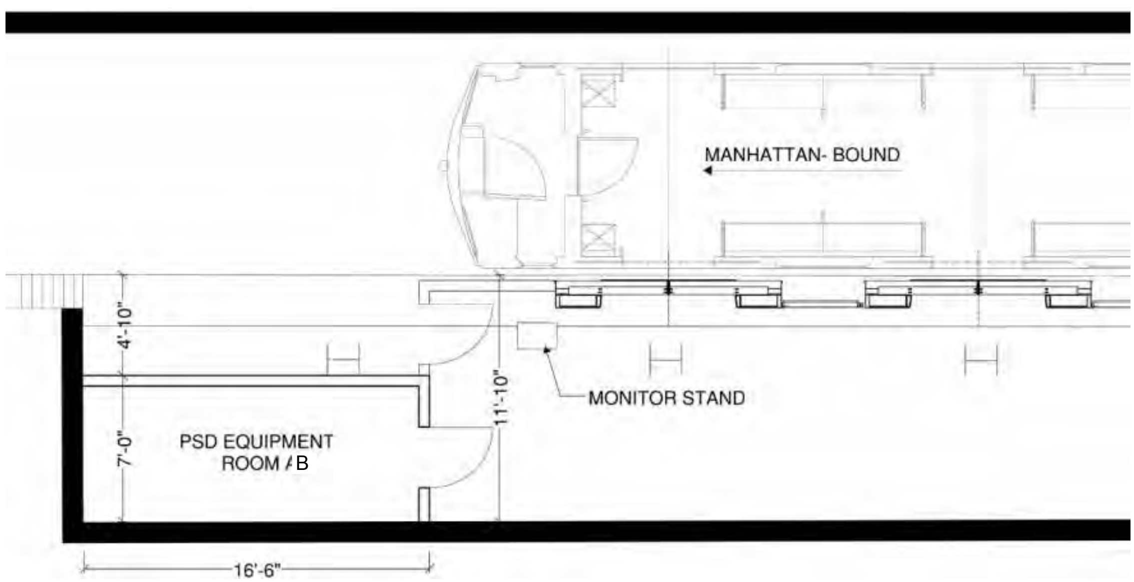

Figure 3 – PSD Equipment Room B Detail (Lower Level) – Wilson Avenue Station

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3 and 4.

Platform obstructions within 5' of edge:

Canarsie-bound: There are no obstructions.

Manhattan-bound: All columns are 41" from platform edge. Presently, one column is in front of the ADA - designated door. However, due to the need to adjust the stop line, this obstruction can be remedied while not compromising other doors.

Lighting:

Existing lighting: On the Manhattan-bound platform linear fluorescent light fixtures are approximately 24" from the platform edge. The Canarsie-bound platform linear fluorescent lighting is hung 3'-6" from the platform edge with a vertical clearance of 7'-4" to the bottom of the fixture. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	130
Station Name	Wilson Avenue
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	37.6
Peak Demand Load, Max Current (A)	130.5
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	295.5
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	104.5
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

Wilson Avenue Station is a historically designated property. As such, design will require review by the New York State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.7M to install APGs and $35.7M to install PSDs (See Appendix E).

Figure 4 – Edge of Platform Condition, Canarsie-bound – Wilson Avenue Station

Table of Contents

Figure 5 – Edge of Platform Condition, Manhattan-bound – Wilson Avenue Station

1.12 Bushwick Avenue Station

Summary: Bushwick Avenue Station (MR-131) is feasible for both APGs and PSDs. On the Manhattan-bound platform, there is a column located in front of an ADA-designated door. The current non-complying condition would not be exacerbated by the implementation of a platform edge barrier. Platform structural work will be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.

Description

Bushwick Avenue Station is a below-grade station with two curved platforms. Stair access is available near middle of both platforms. The platform structures are cast-in-place concrete. Both platforms are approximately 11'-8" wide with columns spaced approximately 15' on center. On both platforms, columns have a tile surround; the faces of the columns are approximately 3'-0" from the platform edge. See figure 1 for an overall station plan and figure 3 for a typical platform view.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

One PSD equipment room measuring approximately 8'-0" x 30'-0" can be located at the north end of the Manhattan-bound track platform (see figure 2).

Track Layout

Track is mildly curved. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: Platform edge appears to be original to station construction, and will therefore require reconstruction to support new platform APGs or PSDs. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5

Platform obstructions within 5' of edge:

All columns are approximately 3'-0" from the platform edge. On Manhattan-bound track platform, there is a column located in front of an ADA-designated door. The current non-complying condition would not be exacerbated by the implementation of a platform edge barrier.

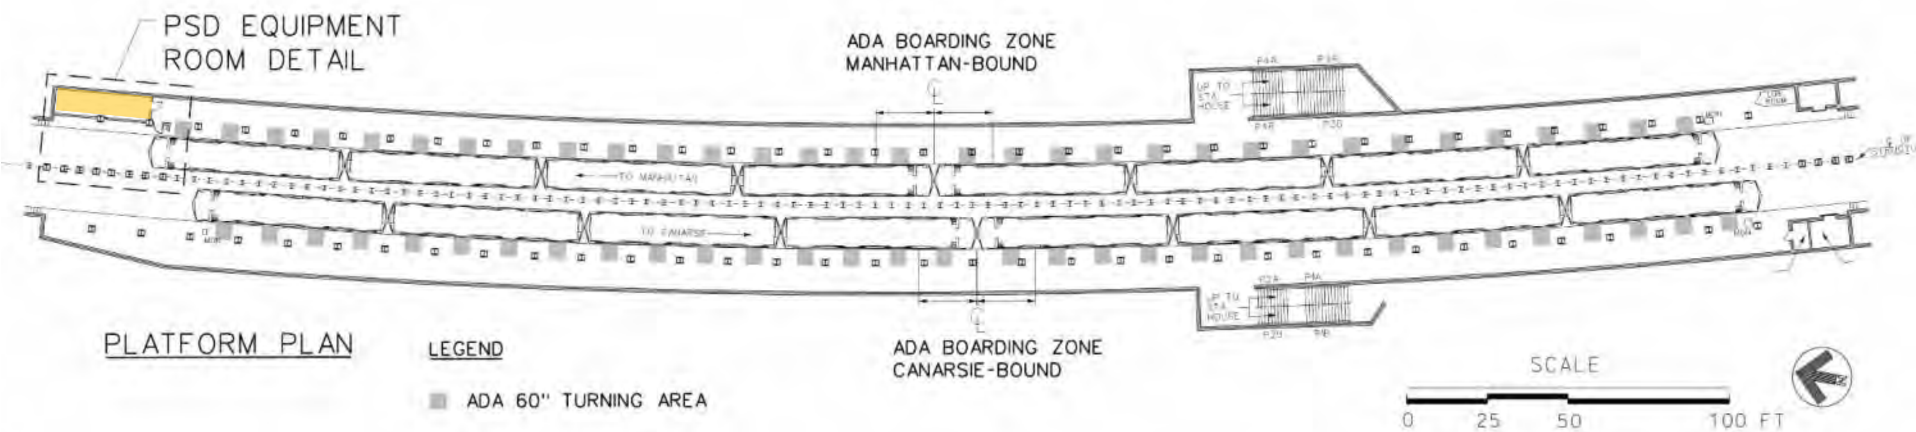

Figure 1- Station Plan - Bushwick Avenue Station

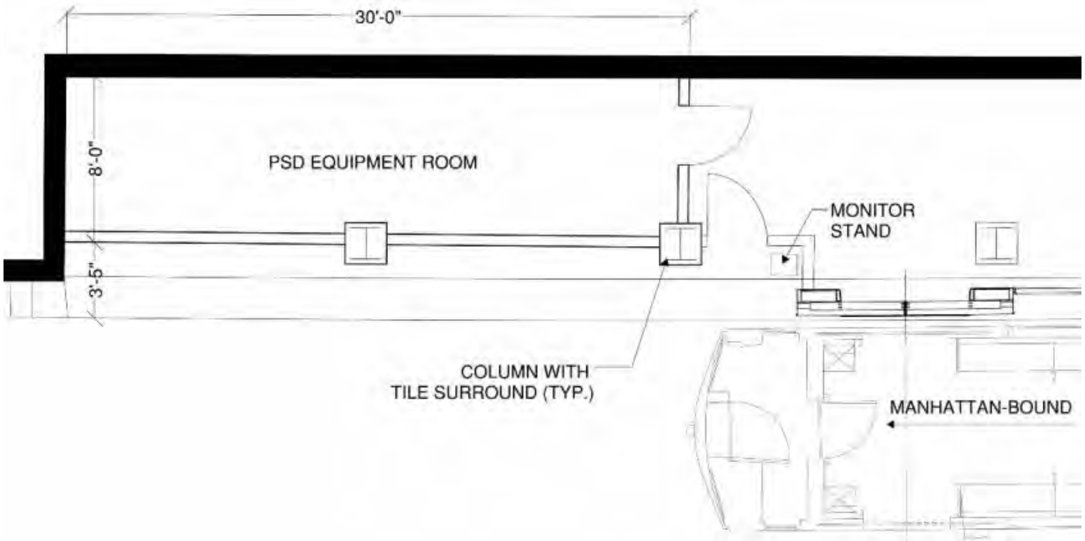

Figure 2 – PSD Equipment Room Detail - Bushwick Avenue Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Canarsie Line Station Electrical Capacity Analysis	
NYC T Station MR Number	131
Station Name	Bushwick Av - Aberdeen St
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	39.6
Peak Demand Load, Max Current(A)	137.4

Total Load (Station Peak + PSD), (A)	302.4
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	97.6
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.6M to install APGs and $35.4M to install PSDs (See Appendix E).

Figure 3 – General view of Canarsie-bound track platform – Bushwick Avenue Station

1.13 Broadway Junction Station

Summary: Broadway Junction Station (MR-132) is feasible for APGs only. As the station has minimal canopy coverage, PSDs would not be feasible. On the Manhattan-bound platform, there is a column located in front of an ADA designated door. The current non-complying condition would not be exacerbated by the implementation of a platform edge barrier. Existing power is adequate.

Description

Broadway Junction Station is an elevated station with one side platform and one center/island platform. The platform structure is made of cast-in-place concrete. Stair access is available at the middle of both platforms. The south end of the center platform widens as the Manhattan-bound track curves eastward. As the center platform widens, the number of column rows increases from 1 to 3. The columns are typically 5'-0" away from both edges of the center platform. The Manhattan-bound platform width varies from approximately 12'-0" to approximately 40'-0". The Canarsie-bound track is tangential to the platform. The platform width varies from approximately 10'-8" to 18'-4". There are columns that support the cantilever station canopy; these columns are typically 10'-4" from edge of platform and are spaced approximately 17'-7" on center. See figure 1 or an overall station plan and figure three for a typical platform view.

Full Height PSDs: As noted in the summary, full height PSDs are not feasible at this station due to the absence of structural support overhead. A new steel overhead structure would be required in areas without a canopy; therefore adding weight, costs, and maintenance.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. At parts of the platform not covered by a canopy, minimal overhead structures would be required to support cameras and sensors.

Equipment Room

Space required for one equipment room (16' x 12') is available at the south side of the center platform (see figure 2).

Track Layout

Track is tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: The platform edge appears to have been updated recently, so it is not likely that structural work would be needed. The 2012 NYCT condition survey report gave the platform edges a rating of 2.5 and 2.0.

Platform obstructions within 5' of edge:

Manhattan-bound: All columns are 5'-0" away from the platform edge. One column is in front of an ADA - designated door; however, the condition is not exacerbated by the implementation of a platform edge barrier.

Canarsie-bound: All columns are approximately 10'-4" from the platform edge. There are no other obstructions.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn
(Broadway Junction Station)

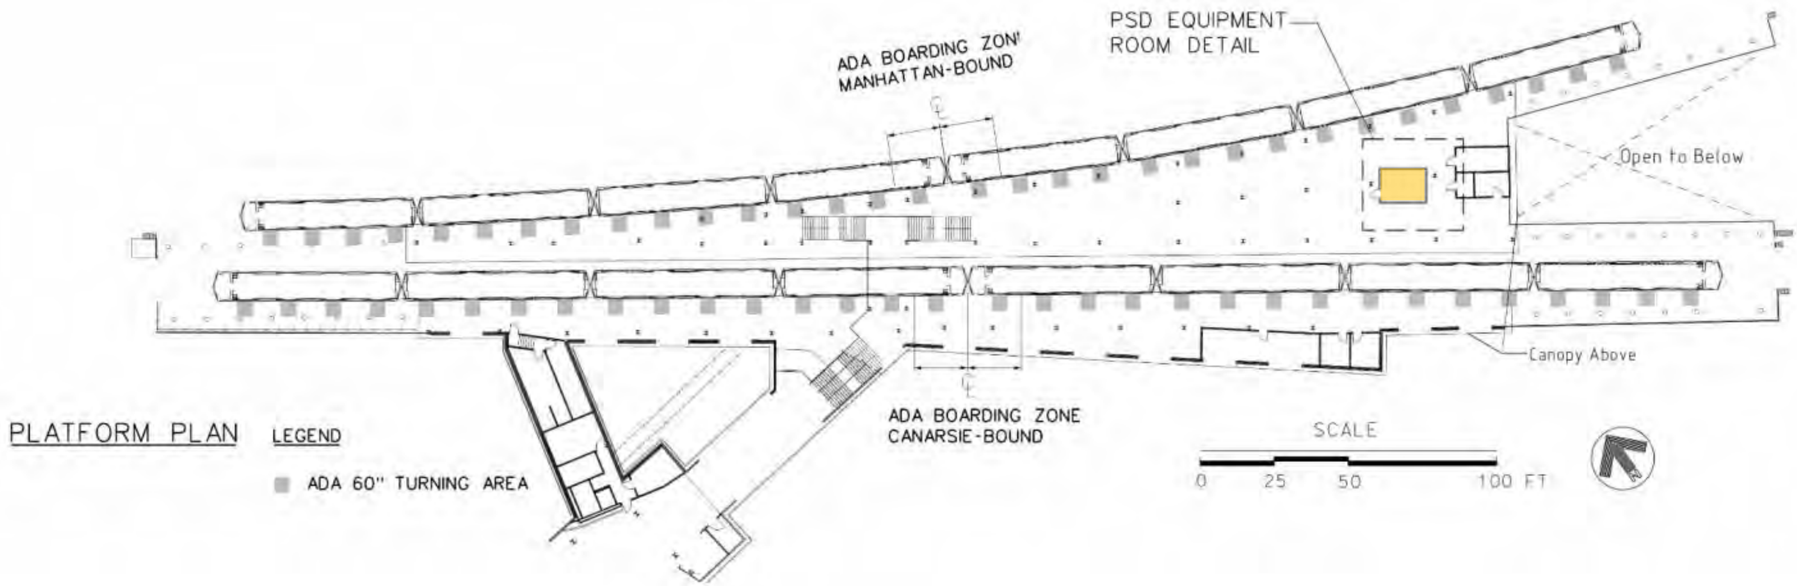

Figure 1 - Station Plan – Broadway Junction Station

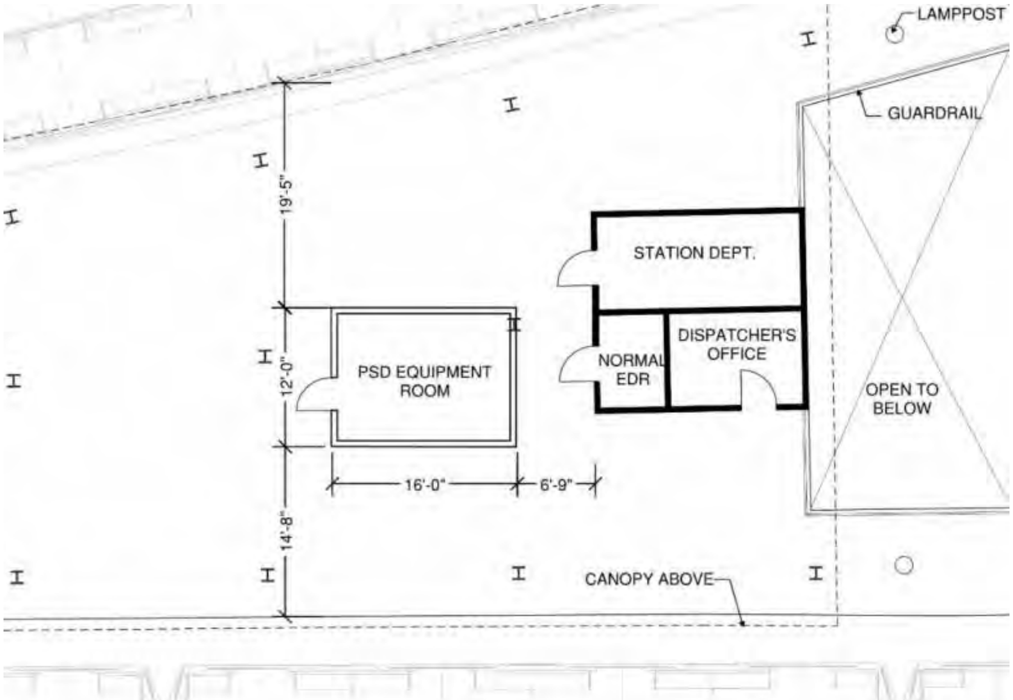

Figure 2– PSD Equipment Room Detail – Broadway Junction Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge (in areas covered by a canopy). Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration. Where there is no canopy, lampposts are located in the center of the platforms.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding (and APGs are the only feasible option at this station).

Canarsie Line Station Capacity Analysis	
NYC T Station MR Number	132
Station Name	Broadway Junction
Peak Demand Load from ConEd Report, Last 20 Months,(kW)	156.0
Peak Demand Load, Max Current (A)	541.3
PSD Total Load for N Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	706.3
Station Service Power Capacity, (A)	1600.0
Service Spare Capacity, (A)	893.7
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.9M to install APGs (See Appendix E).

Figure 3 – Uncovered platform with canopy in the distance– Broadway Junction Station

1.14 Atlantic Avenue Station

Summary: *Atlantic Avenue Station (MR-133) is not feasible for APGs or PSDs because an existing non-compliant condition in the ADA boarding zone would be exacerbated (see figure 3). Figure 2 locates the ADA boarding zone on the overall station plan. Contributing to this finding are other constraints including the width of the platform. The platform is 15'-3" wide, which does not meet the minimum required center/island platform width of 15'-10" for emergency egress with platform edge barriers implemented (see Emergency Egress Width Analysis; Appendix C).*

Description

The Atlantic Avenue Station is elevated, consisting of one tangent platform serving two tracks. The platform structure is cast in place concrete. The platform has two (2) rows of columns spaced 3'-5" from the edge of the platform at 20'-0" intervals for the length of the canopy. The canopy covers only 2/3 of the platform. The platform has a typical width of 15'-3" (see figure 1).

Figure 1 – General view of platform width and canopy – Atlantic Avenue Station

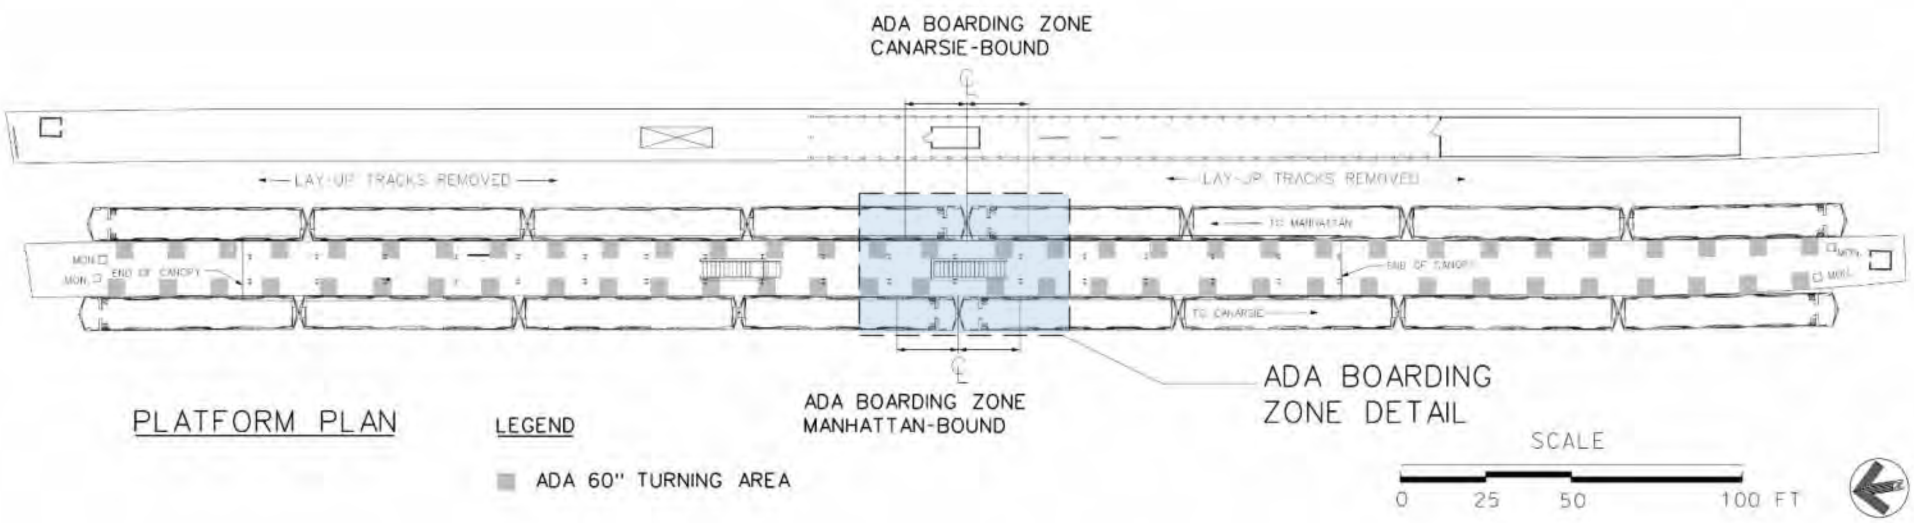

Figure 2 – Station Plan – Atlantic Avenue Station

Obstructions within 5' of edge:

Manhattan Bound: All columns are 3'-5" the platform edge. At the ADA boarding zone, there is a stair 5-0" from the platform edge. While the required turning radius is met, the implementation of a platform edge barrier would create very narrow/non-compliant circulation widths to the sides of this stair and adjacent columns.

Brooklyn Bound: All columns are 3'-5" from the platform edge. At the ADA boarding zone, there is a stair 4'-7" from the platform edge. At one of the doors, this would exacerbate an already non-compliant condition (see figure 3). Adjusting the stop line would not remedy the issue as there would continue to be interference with the stair.

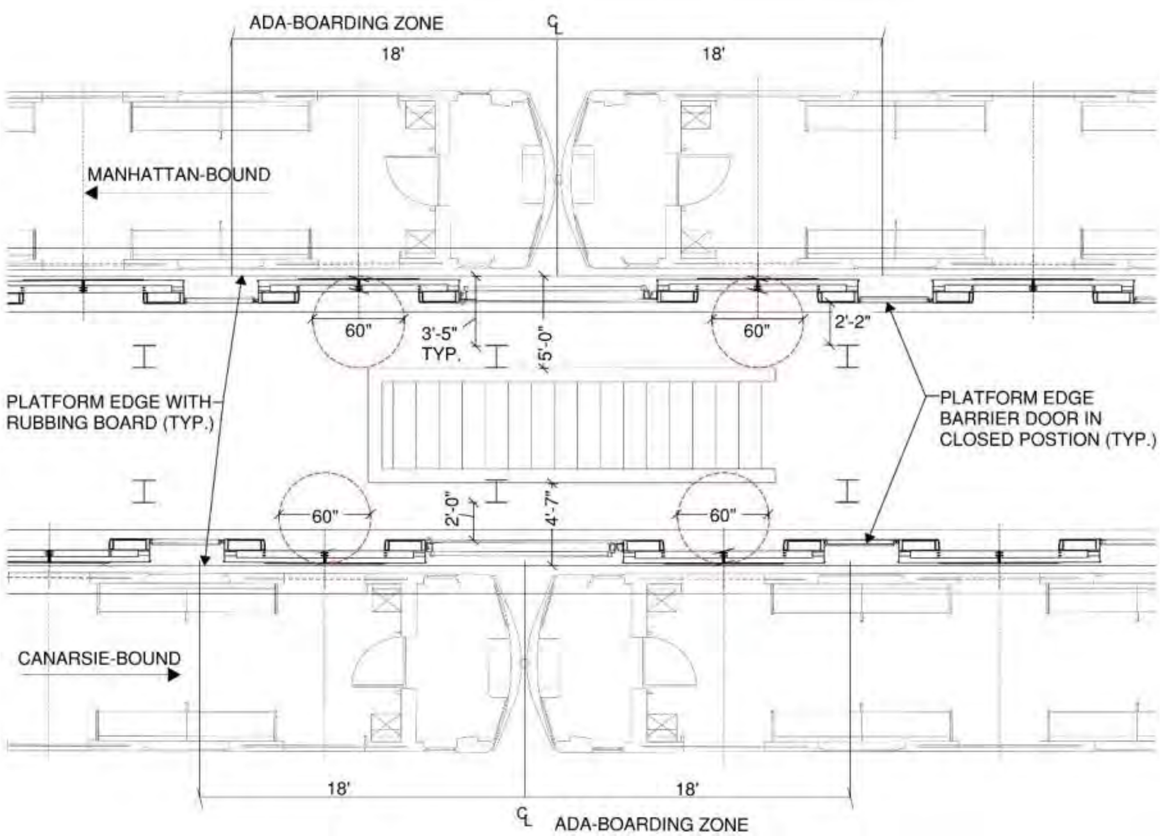

Figure 3 – ADA Boarding Zone Detail – Atlantic Avenue Station

Table of Contents

1.15 Sutter Avenue Station

Summary: Sutter Avenue Station (MR-134) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

Sutter Avenue Station is an elevated station with two side platforms. Both platforms are straight with columns along the back wall of the platform. The canopy covers the majority of the station, with a small part of the north-end uncovered. The platforms have a typical width of 7'-6" with 6'-0" clear to the face of the columns. See figure 1 for a typical platform view.

Figure 1 – Typical Platform View- Sutter Avenue Station

Table of Contents

Figure 2 – Precast T-Beam platform - Sutter Avenue Station

Table of Contents

1.16 Livonia Avenue Station

Summary: Livonia Avenue Station (MR-135) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform (see structural report; Appendix B and figure 3). Contributing to this finding is the location of a staircase on the Manhattan-bound platform. Staircase P2 is located 12" away from the platform edge; 15" are needed to accommodate a platform edge barrier (see Figure 2).

Description:

Livonia Avenue Station is an elevated station consisting of two side platforms serving Manhattan-bound and Canarsie-bound tracks. Each platform has a tangent geometry with one row of columns approximately 6'-0" from the edge of the platform. These columns are approximately 10'-0" on center, and support the station canopy. The canopy only covers the middle third of the platform. See figure 1 for a typical platform view of Livonia Avenue Station.

Figure 1 – Canarsie-bound platform, typical platform condition– Livonia Avenue Station

Figure 2 – Manhattan-Bound track platform, Staircase P3 is 12" away from platform edge – Livonia Avenue Station

Figure 3 – Elevated Precast T-Beam platform – Livonia Avenue Station

1.17 New Lots Avenue Station

Summary: *New Lots Avenue (MR-136) is not feasible for APGs or PSDs as parts of the Canarsie-bound platform are 5'-7" wide, which does not meet the minimum required side platform width of 5'-11" for emergency egress with platform edge barriers implemented (see Emergency Egress Width Analysis; Appendix C and figure 1). In addition, on the Manhattan-bound platform, a stair is located 12" away from the platform edge; 15" are needed to accommodate a platform edge barrier.*

Description

New Lots Avenue is an elevated station consisting of two side platforms serving Manhattan-bound and Canarsie-bound tracks. Each platform has a tangent geometry with one row of columns that are 5'-7" away from the platform edge. These columns are spaced 15'-0" on center, which support the station canopy. The canopy covers about one half of the platform length.

On the Manhattan-bound platform, staircase P3 located 12" from the platform edge. This staircase does not allow for the installation of the barrier. (See Figure 2)

Figure 1–Columns are typically 5'-7" from the platform edge– New Lots Avenue Station

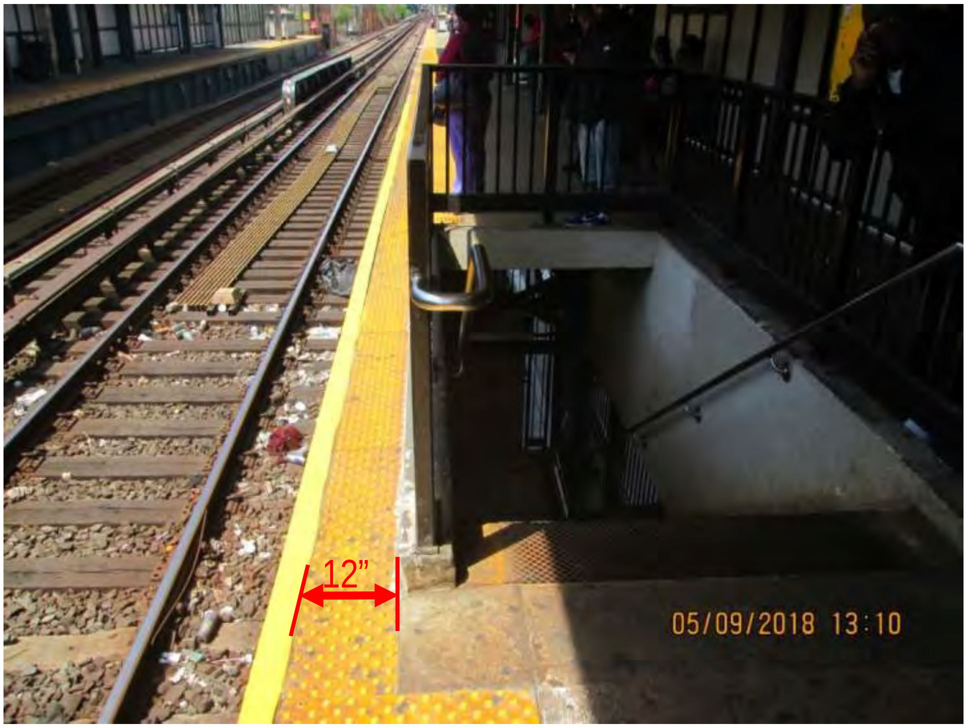

Figure 2– Manhattan-Bound track platform, Staircase P3 is 12" away from platform edge – New Lots Avenue Station

1.18 East 105th Station

***Summary:** East 105th Station (MR-137) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description:

East 105th Station is an at-grade station consisting of one center/island platform serving two tracks. The platform is 10'-4" wide. The platform is straight with one row of columns spaced 20'-0" on center, supporting the station canopy. The canopy only covers approximately one quarter of the platform length. See figure 1 for a general platform view of East 105th Station.

Figure 1– General Platform Condition – East 105th Station

Figure 2– Precast T-Beam platform – East 105th Station

Table of Contents

1.19 Rockaway Parkway Station

Summary: Rockaway Parkway (MR-138) is not feasible for APGs or PSDs. There is a portion of the platform where the effective cumulative width for passenger movement is approximately 9'-0" wide, which does not meet the minimum required center/island platform width of 9-10" for emergency egress with platform edge barriers implemented (see Emergency Egress Width Analysis; Appendix C).

Description:
Rockaway Parkway Station is an at-grade station consisting of one center/island platform serving two tracks. It is the terminating station of the L-line in Canarsie. The platform structure is cast-in-place concrete. The platform has a tangent geometry with two rows of columns with longitudinal spacing of 20'-0" on center. Track 1 (West) has column faces that are 3'-5" from the edge of the platform and Track 2 (East) has column faces that are 3'-10" from the edge of the platform. The platform width varies from 16'-6" to 24'-8". At the north-end, the platform divides due to an office structure in the middle, resulting in a platform width at the east-side of 4'-7" wide (see Figure 1) and west-side of 4'-5" for approximately 80' of the platform length.

Figure 1 –Effective platform width at Track 2 side, looking south- Rockaway Parkway Station

1.20 8th Avenue Station

Summary: 8th Avenue Station (MR-115) is feasible for both APGs and PSDs. Platform structural work will be required to support the added load of an APG platform edge barrier, though a PSD barrier could be supported without any additional structural work (see structural report; Appendix B). Existing power is adequate.

Description

The 8th Avenue Station is below-grade with a straight center/island platform. It is a terminal station. The platform structure is cast-in-place concrete. Back-of-house elements are located at the ends of the platform and in the mezzanine. There are four staircases along the length of the platform and a centrally located elevator. The platform width is 19'-4". Columns are spaced approximately 15' on center and are located 4'-3" from the platform edge. There is a significant amount of ceiling-mounted conduit above the northern platform edge. See figure 1 for an overall station plan. Figures 3 and 4 show platform conditions.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Existing wall-mounted conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

An 8'-0" x 30'-0" PDS equipment room can be located in the middle of the platform, adjacent to the Ejector room.

Track Layout

Track is nearly tangent, although it is slightly curved at the east end of platform. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

Existing conditions: The station platform was recently renovated according to NYCT structural / architectural standards. As such, it can sustain the load of PSD installation, however it must be reconstructed for installation of APGs.

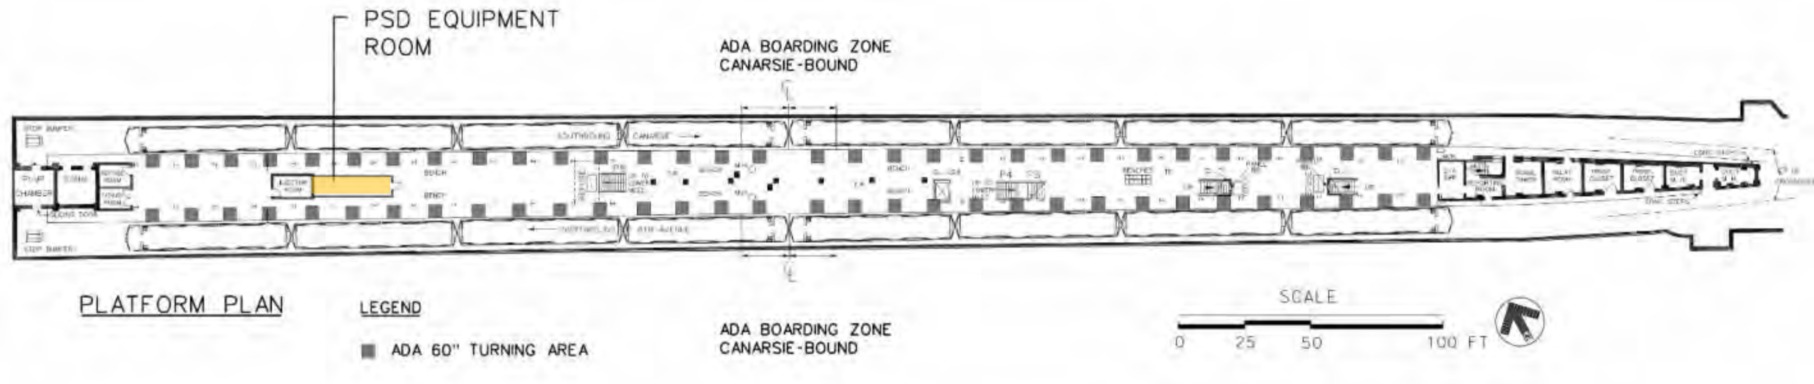

Figure 1 – Station Plan – 8st Avenue Station

Platform obstructions within 5' of edge:

Northern platform: columns are approximate 4'-3" from platform edge at most locations. As such, there are no physical obstructions which limit accessibility.

Southern platform: columns are approximate 4'-3" from platform edge at most locations. As such, there are no physical obstructions which limit accessibility with the exception of Elevator EL-224 which sits 4'-0" away from the platform edge, thereby obstructing the ADA turning radius. However, the introduction of platform edge barriers will not further impact accessibility.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Not expected to be an issue for installation of platform edge barriers.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Appendix A: Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

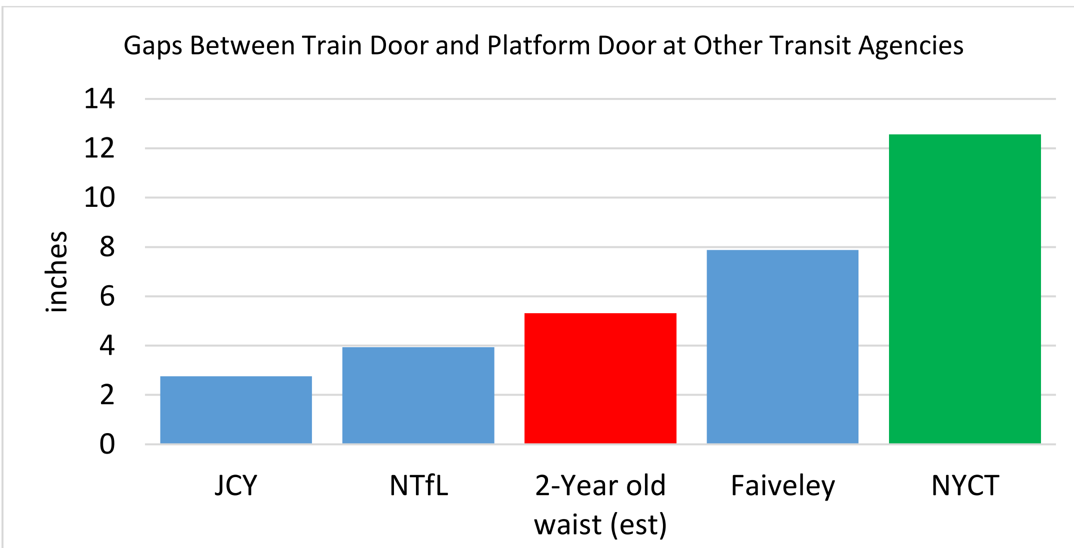

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

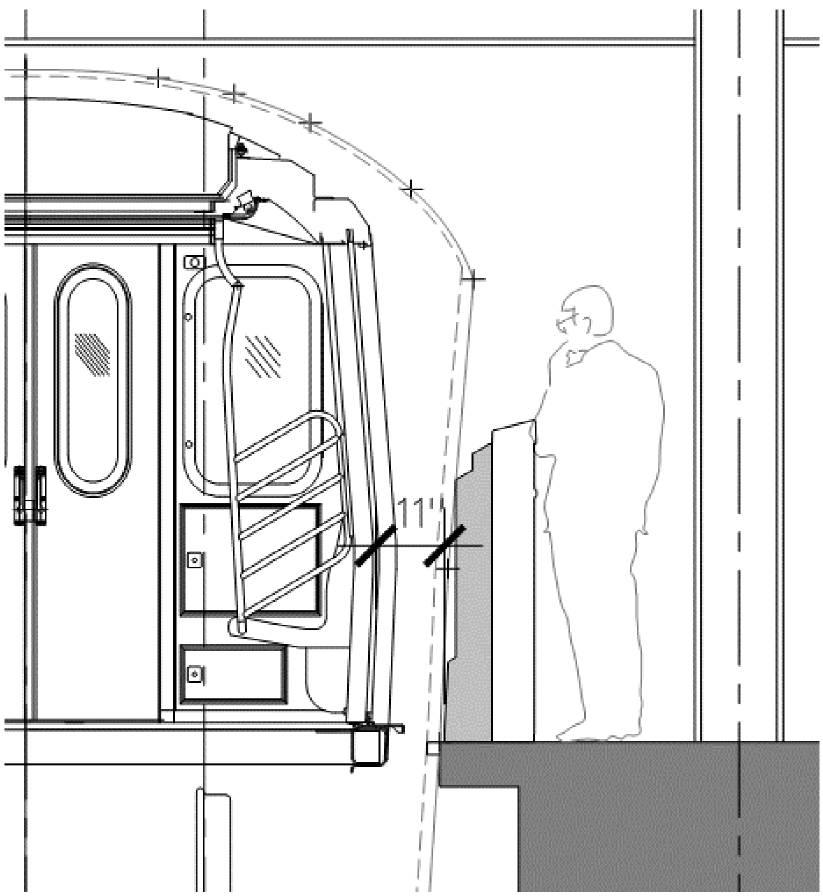

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the “ON” position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the ‘PSD Closed and Locked’ (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that ‘PSD Closed and Locked’ indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that ‘PSD Closed and Locked’ indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train’s removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	**3rd Ave.**	**6th Ave.**	**14 St / Union Square**	**1st Ave.**
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

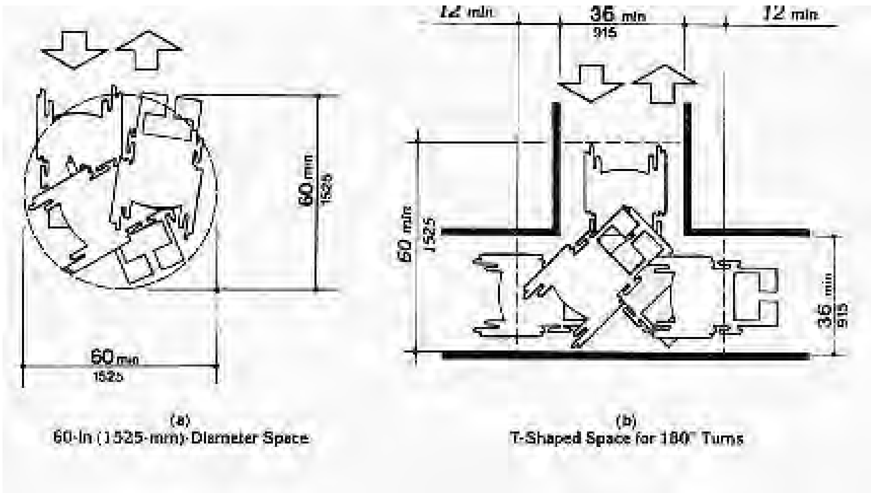
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

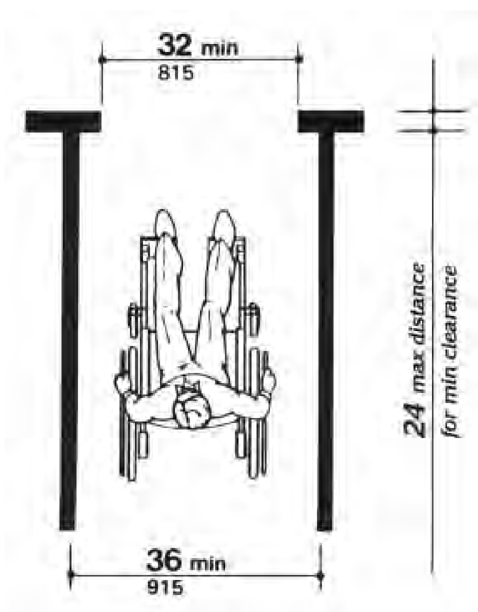


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

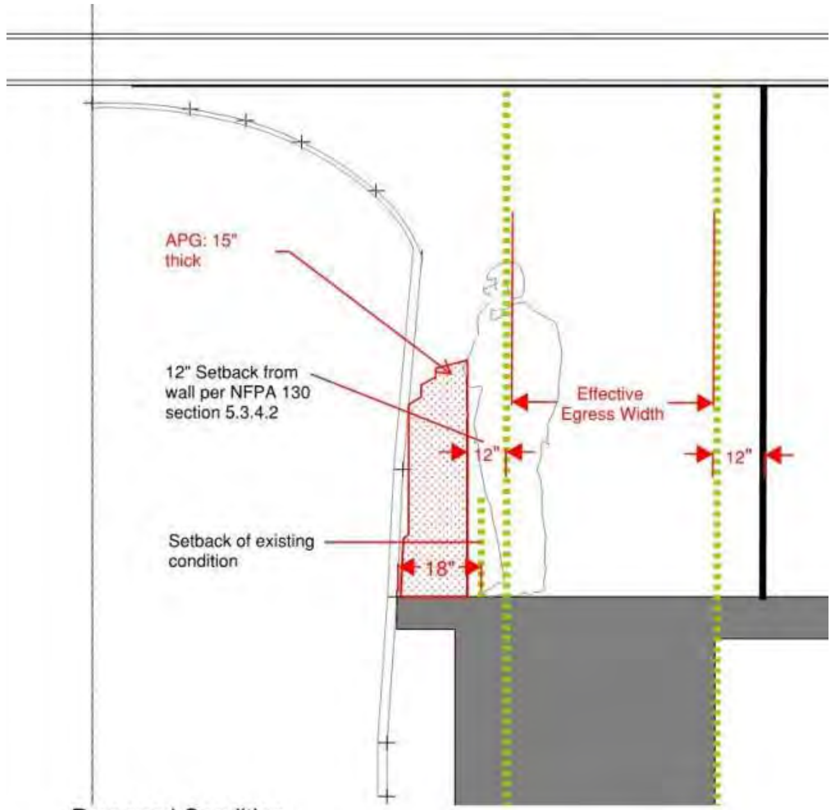
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

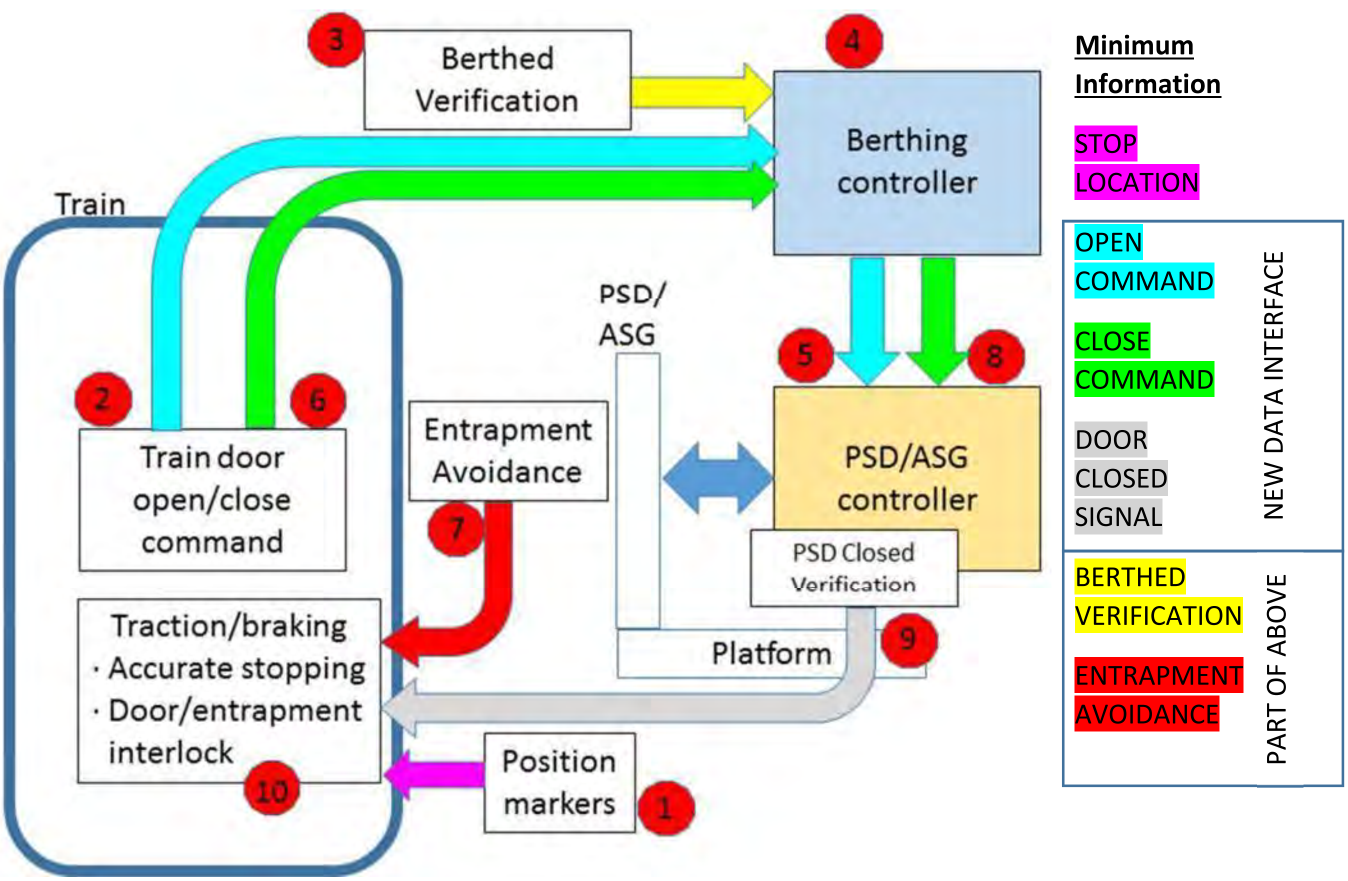
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

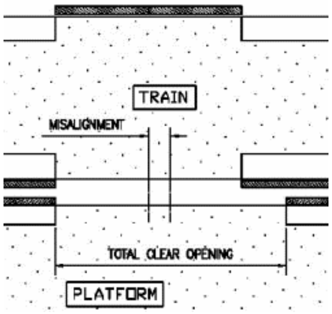
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

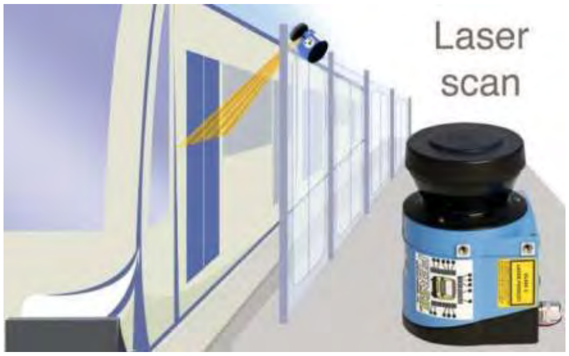
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

End of Appendix

Appendix B – Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

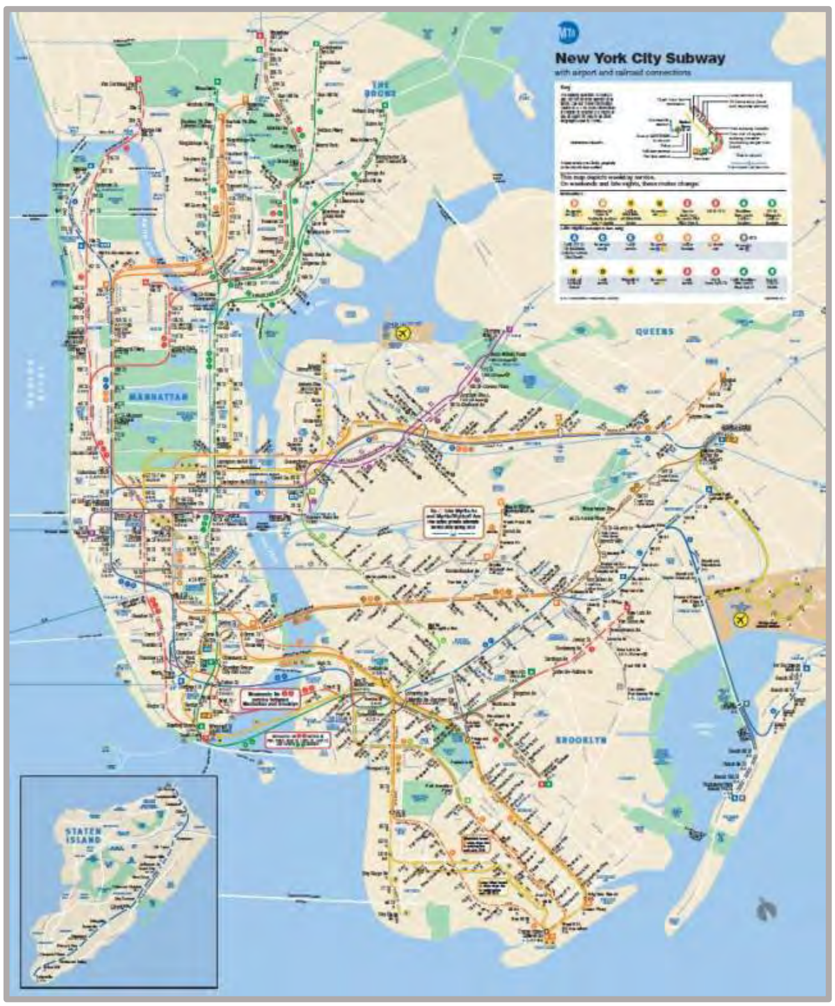


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

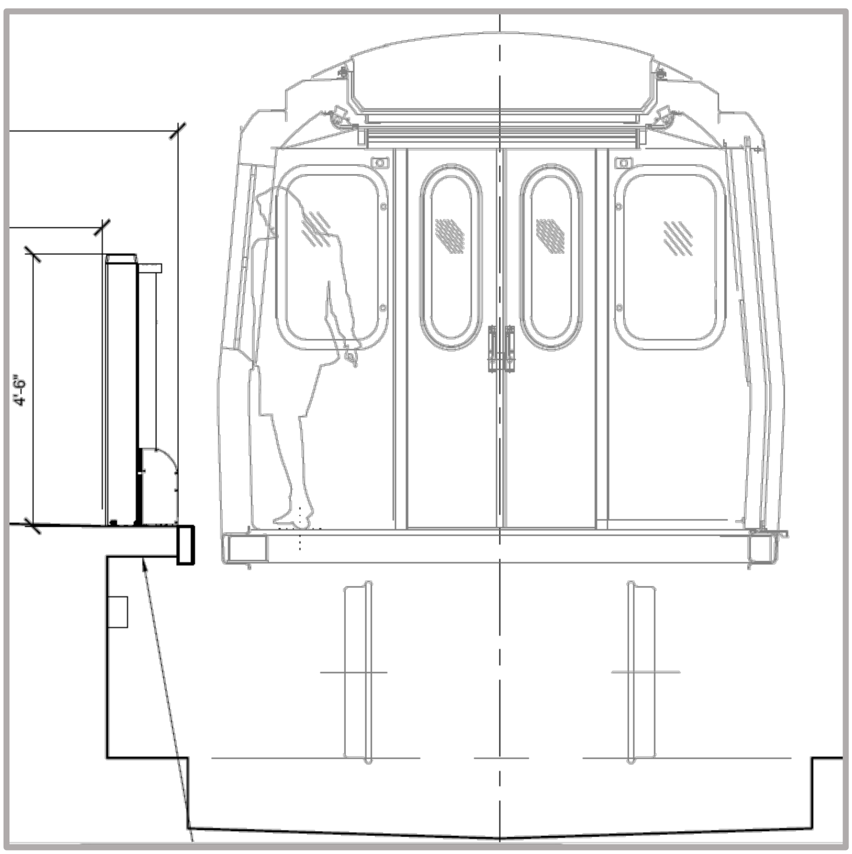

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 $lbs/ft.^2$ (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

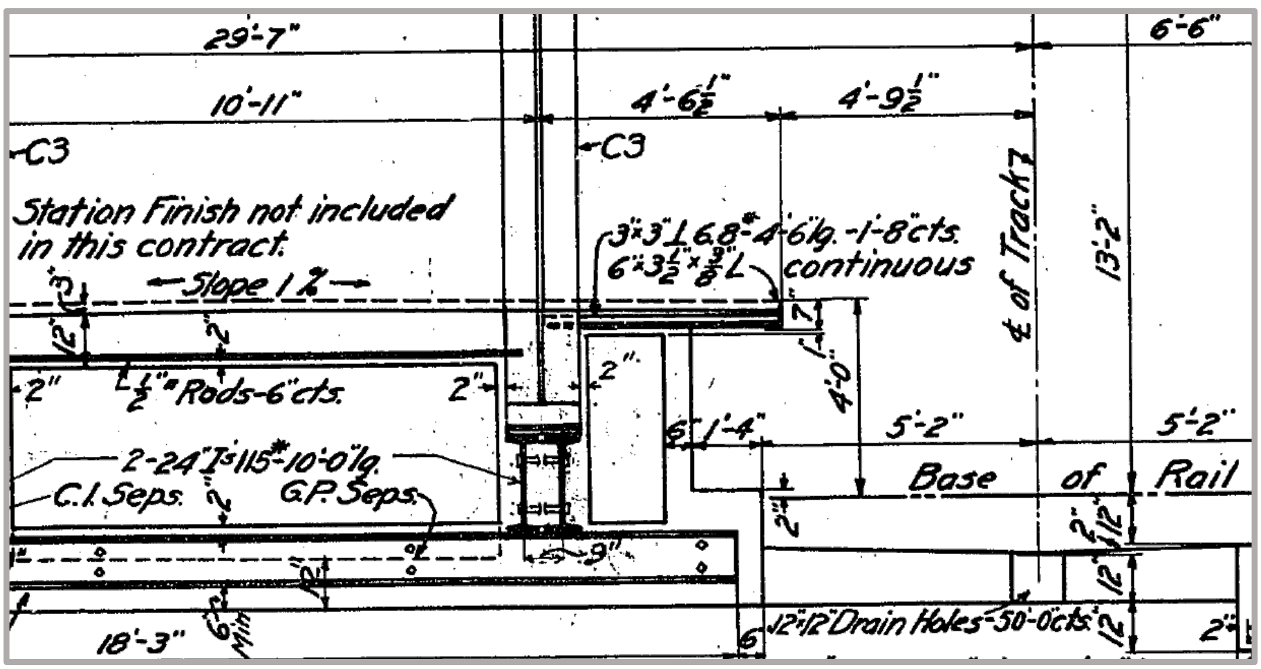

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

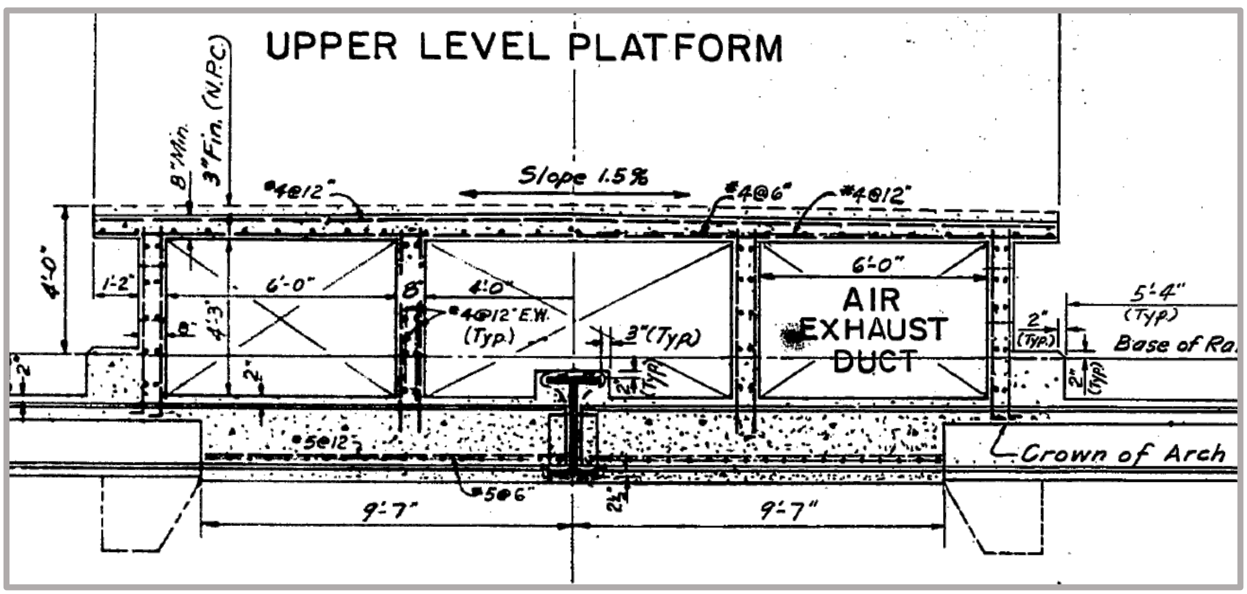

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

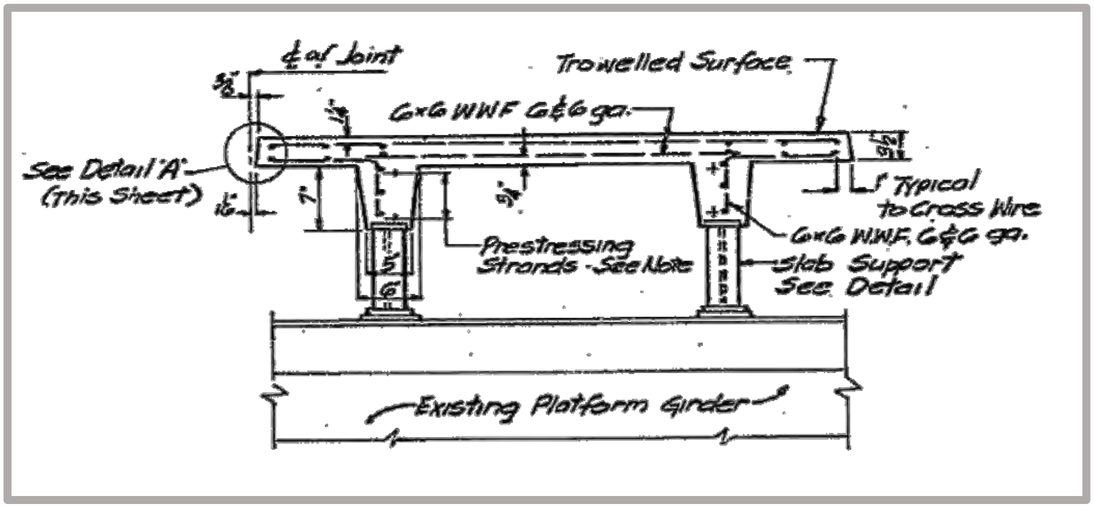

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

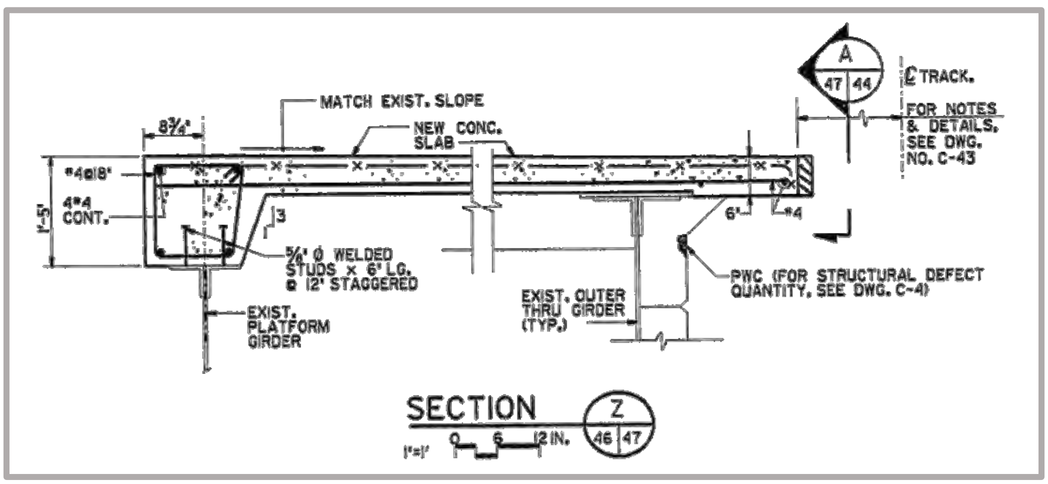

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

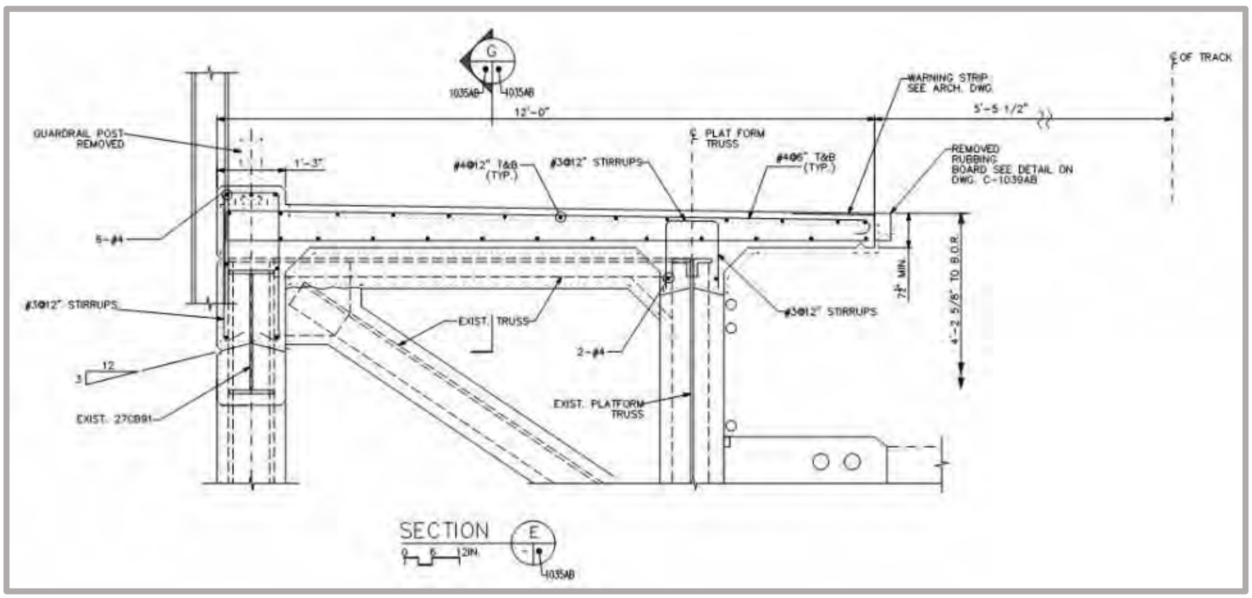

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

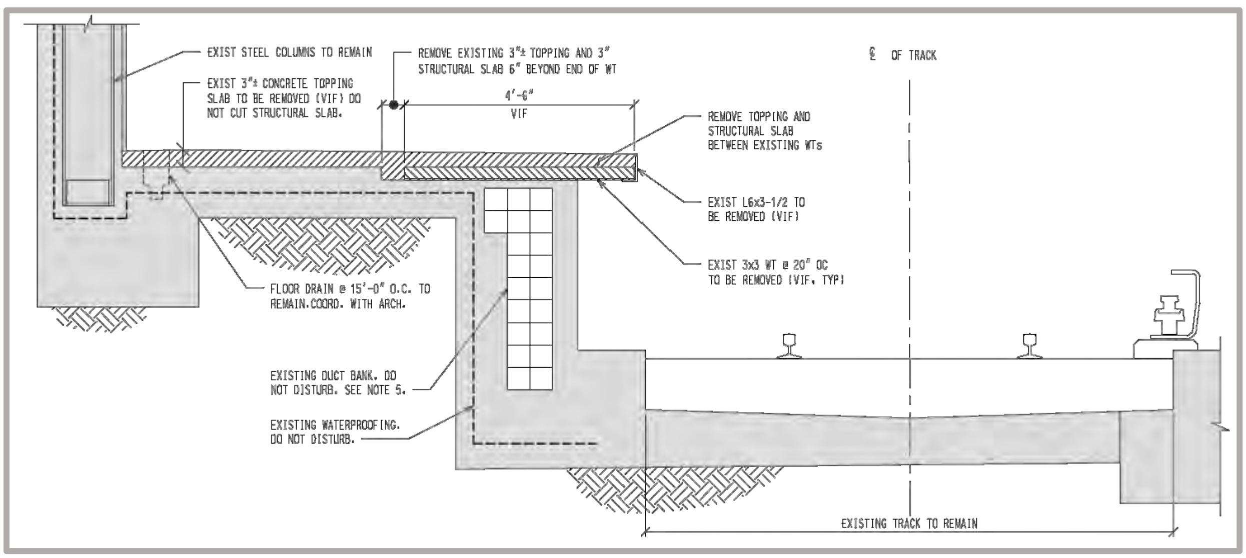

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

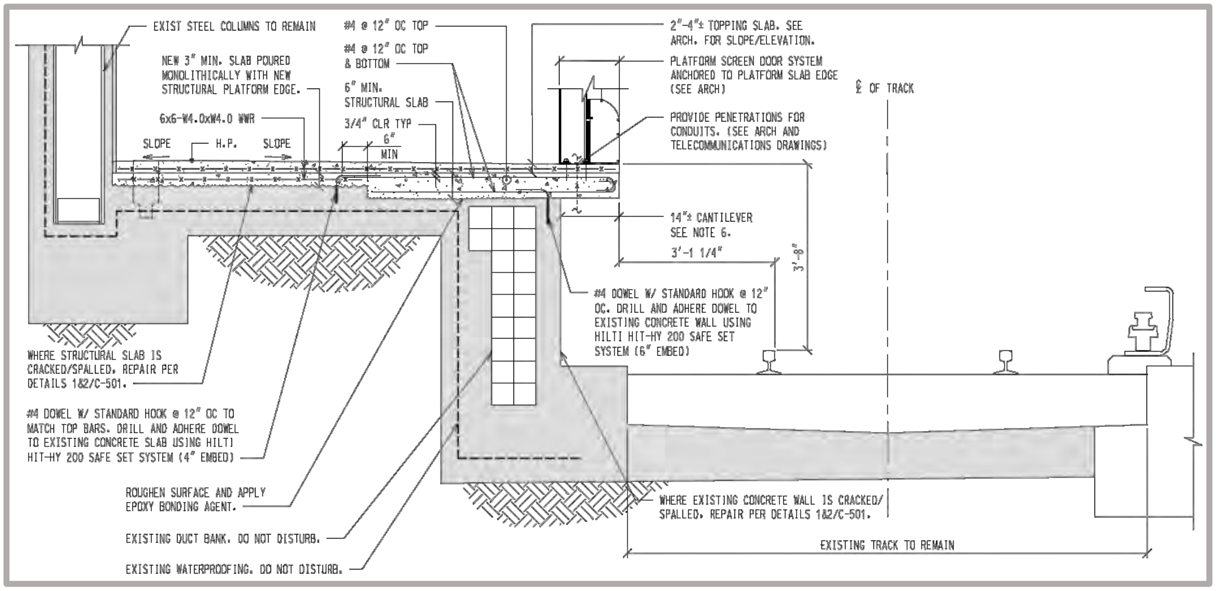

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

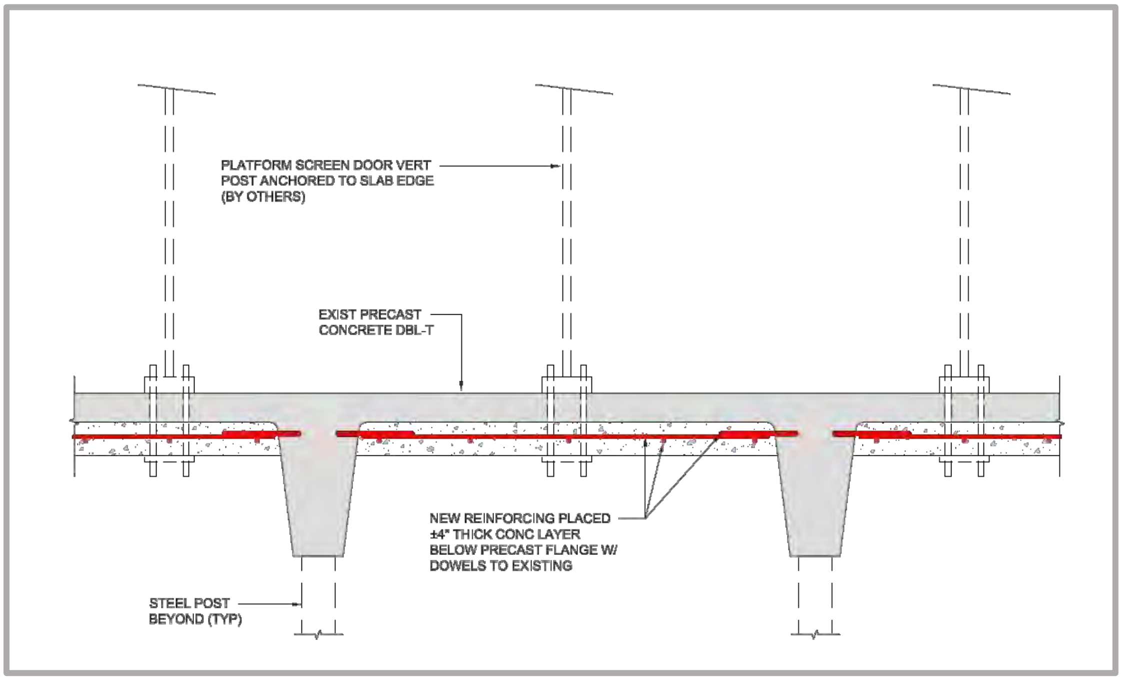

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C – Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5’ – 11” of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

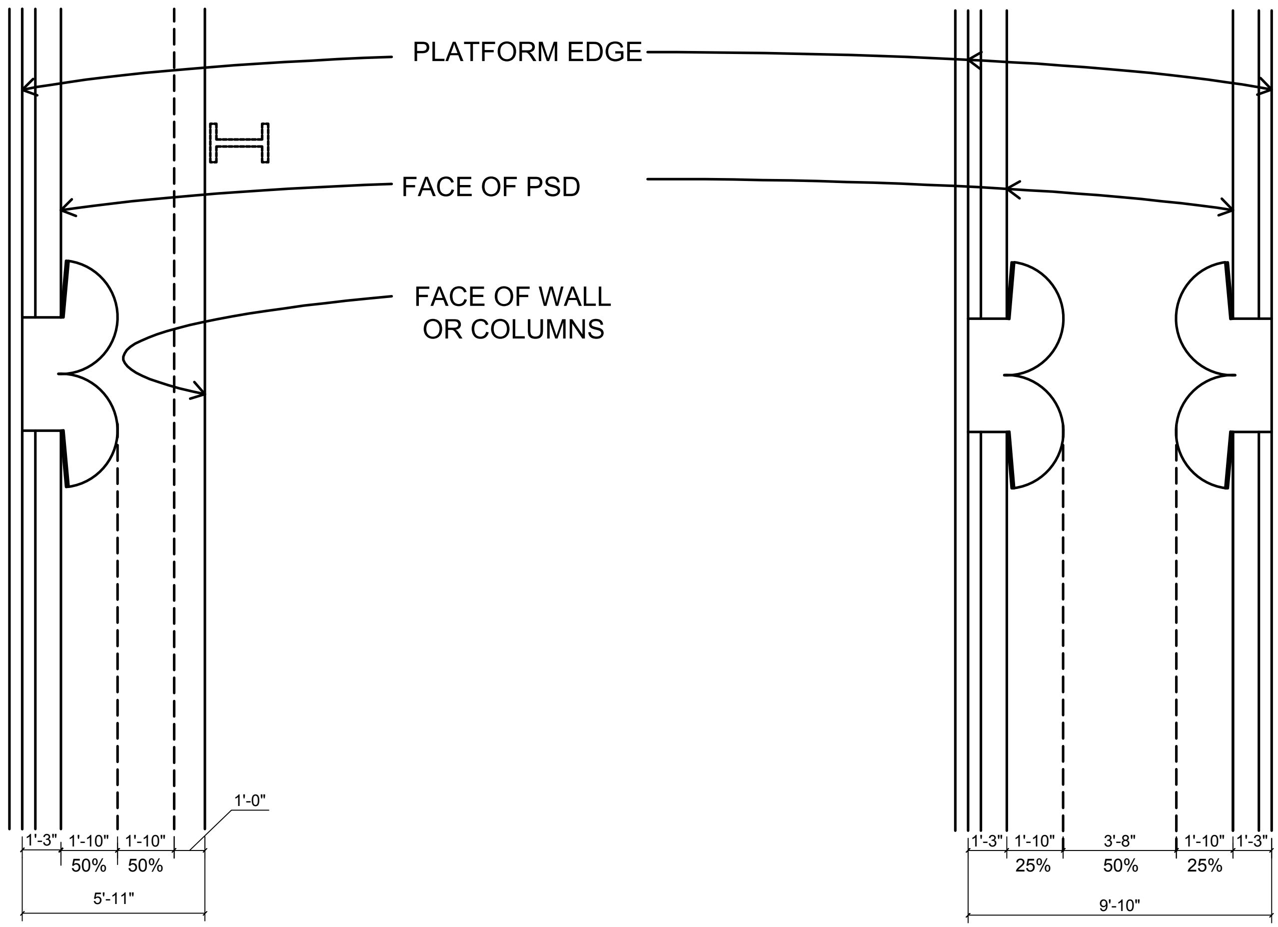

FIGURE 1 – SIDE PLATFORM

FIGURE 2 – CENTER PLATFORM

Appendix D: Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Manhattan

6.0 Station Descriptions

6.1 6th Avenue Station

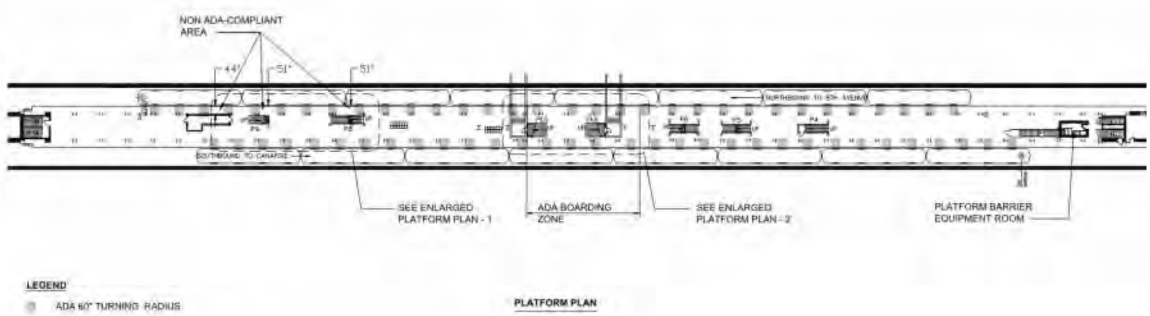

Figure 11 - Key Plan - 6th Avenue Station

Equipment Room

Space required for equipment room is available at the end of the platform.

Track Layout

Track is tangent. No excessive gaps are anticipated.

Platform edge condition

Existing conditions: Retrofitted fiber reinforced polymer panels laid on top of existing concrete cantilever; orange abrasive strip with likely asbestos content. The 2012 NYCT condition survey report gave the platform edges a rating of 4 and 4.5. Platform structural work will be required.

Platform obstructions within 5' of edge:

Brooklyn Bound: All columns are 41" from platform edge. One column is centered on the ADA - designated door; this obstruction can be remedied by moving the stopping location of the train.

8th Avenue Bound: All columns are 41" from platform edge; at the west end, stairs P-8 and P-9 sit 51" away from the platform edge for a length of 15' each. (see enlarged plan PSK-3.2). In addition, there is an ejector room which sits 44" from the platform edge for a length of 30'

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Not expected to be an issue if APGs are employed.

Ventilators:

Per the NYCT MOW drawings, ventilators are indicated over both tracks at the east and west end of the station. However, facilities have been added to the lower mezzanine which may block air flow to these ventilators

Power:

Power is adequate. (see power summary)

Historic Restrictions:

None

Conclusion:

6th Avenue Station is not an acceptable candidate for the installation of a pilot platform edge barrier due to the creation of a non-compliant ADA dimension preventing movement along the platform edge at stair P8. The installation would cause the following negative effects:

- On the Brooklyn bound side, the existing position of the aft ADA door in front of a column will be further constrained by the addition of the barrier. This can be remedied by moving the stopping location of the train.
- On the 8th Avenue bound side, the installation of the barrier will cause an existing pinch point of 41" to be reduced to 26" – less than an acceptable ADA clearance for movement along the platform. To remedy this would require relocation of stair P-8. Per the NYCT ADA Chief, (see ADA summary) the stair reconstruction would trigger mandatory installation of elevators to the street.

Appendix D - Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Manhattan
(3rd Avenue Station, 14th Street Station, 6th Avenue Station, and 1st Avenue Station)

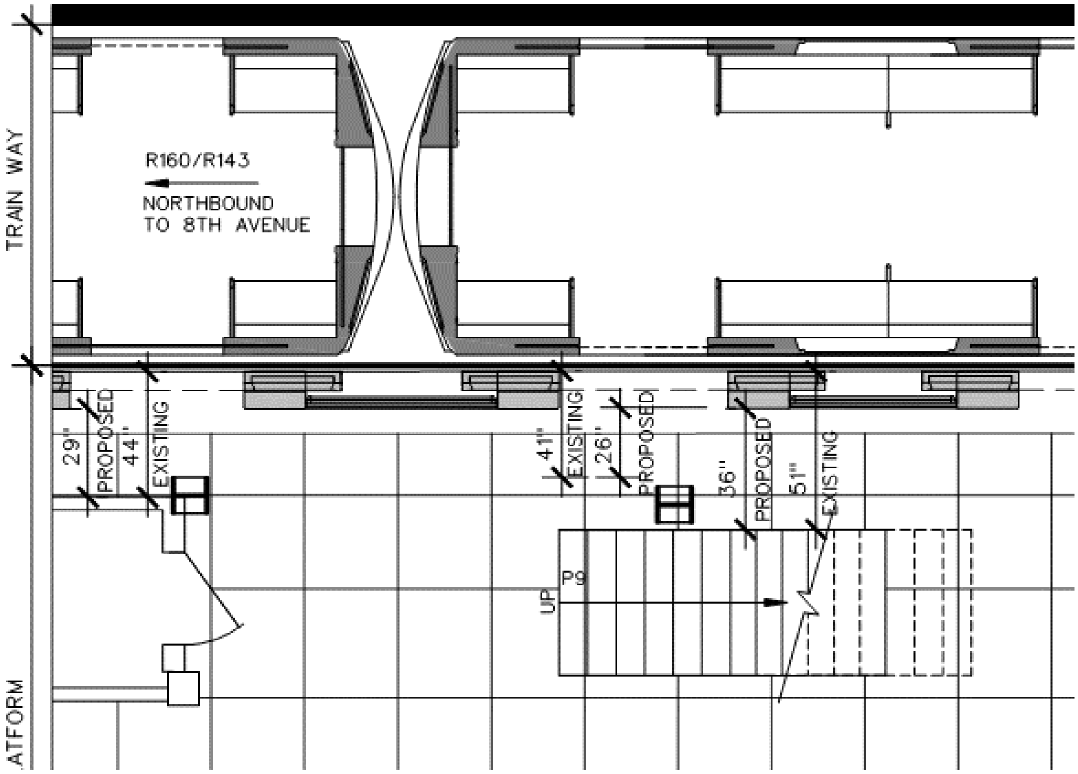

Figure 12 - Detail of clearances at 8th Ave-bound platform; see photo below – 6th Avenue Station

Figure 13 - Constrained space at 8th Ave-bound platform – 6th Avenue Station

6.2 14th Street Station / Union Square

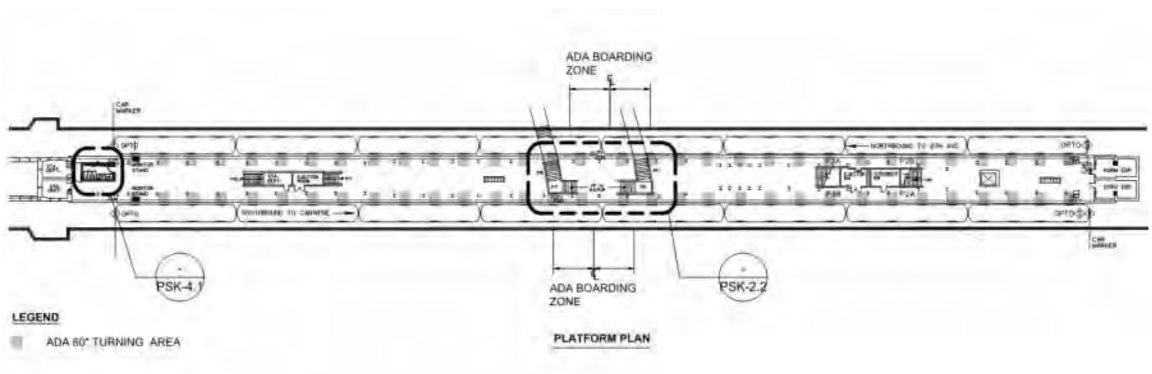

Figure 14; Key Plan – 14th Street / Union Square Station

Equipment Room

Space required for equipment room is available at the end of the platform.

Track Layout

Track is tangent. No excessive gaps are anticipated.

Platform edge condition

Existing conditions: Ceramic tactile tiles laid on top of reconstructed concrete cantilever with polyethylene rubbing board. The 2012 NYCT condition survey report gave the platform edges a rating of 2.5. Despite this good rating, platform structural work will likely be required to support the added load of the platform edge barrier.

Platform obstructions within 5' of edge:

Brooklyn Bound: column distance from platform edge varies; at east and west ends, columns are approximately 42" from platform edge; at center third of platform, columns are 30" from platform edge. Stairs P6 and P7 (to BMT Broadway line) effectively form a wall at 48" from the platform edge for a length of approximately 15'. Stair P6 is located at the ADA-designated door.

8th Avenue Bound: column distance from platform edge varies; at east and west ends, columns are approximately 42" from platform edge; at center third of platform, columns are 28" from platform. The stairs P6 and P7 mentioned above do not block movement on this side of the platform.

Lighting:

Existing lighting: Linear fluorescent in extruded aluminum housing, approximately 12" from platform edge. Not expected to be an issue if APGs are employed.

Ventilators:

Per the NYCT MOW drawings, no ventilators are present. However one set of ventilators was observed at the west end of the Brooklyn-bound track

Power:

Power is adequate. (see power summary)

Historic Restrictions:

14th Street/ Union Square station is on the National Historic Register. As such, any alteration will require review and approval by SHPO.

Conclusion:

14th St / Union Square Station is not an acceptable candidate for the installation of a pilot platform edge barrier due ADA code, historic restrictions, and construction coordination issues. The installation would cause the following negative effects:

- On the Brooklyn bound side, the existing position of the forward ADA door in front of stair P-6 currently has a 48" landing dimension between platform edge and wall. This non-compliant dimension will be worsened with the installation of the platform edge barrier which will bring the dimension down to 33". Efforts to remedy this by moving the stopping location will only bring other doors into non-compliance. The only possible solution would be to reconstruct the stair further away from the platform edge. However, another NYCT capital project currently in design (Planning No.ST01-7935), seeks to widen the stair due to crowding at the station.

- On the Brooklyn bound side, at the same stair P-6, there is an existing pinch point of only 30" between platform edge and column preventing ADA movement along the platform (32" min.). This situation will be worsened by the installation of the platform edge barriers which will reduce the dimension to 15". Not only is this non-compliant for ADA, it also is clearly non-compliant with respect to the building code. A possible alternative route features a 29" space – still less than the code minimum 32" for a doorway.
- This station is on the National Historic Register. This presents a risk factor for the expeditious advancement of the PSD project. While the probability of success is better than 50%, there could be numerous delays during the review process, and SHPO may require alterations to the design.
- The concurrent project mentioned in the first bullet (Planning No.ST01-7935) proposes to reconstruct two platform stairs and install an escalator at the center of the platform. This presents a risk factor in that two contractors will be competing for space on the platform, and both will be under the same schedule restrictions requiring completion when the river tunnel reopens.

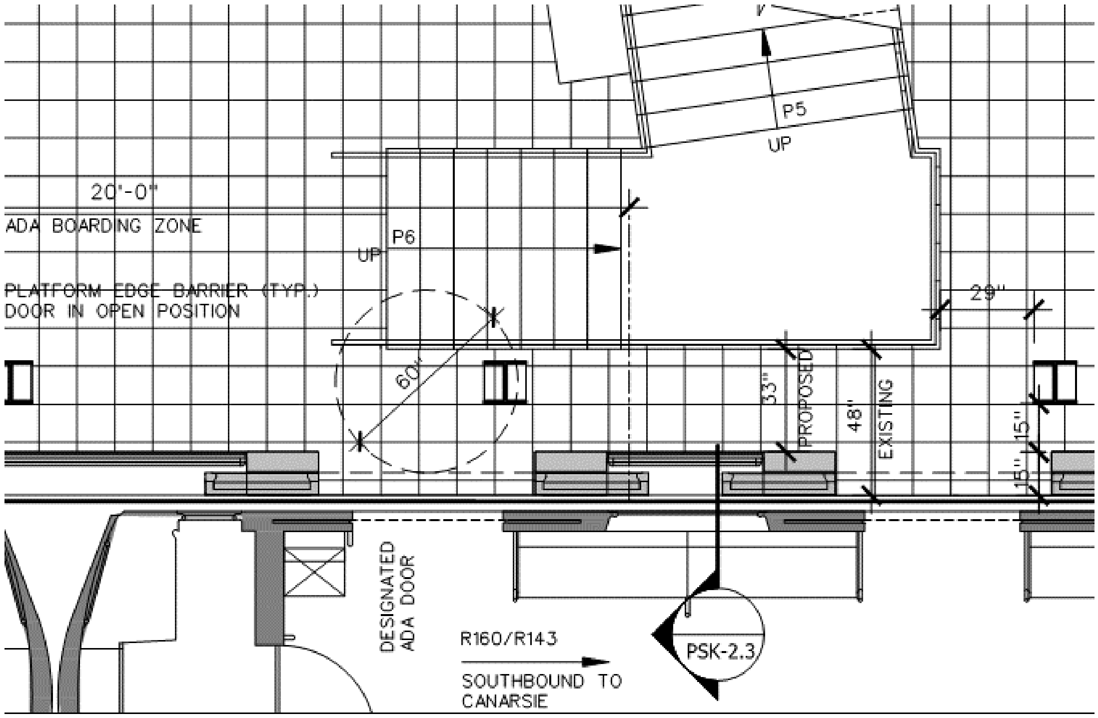

Figure 15 - Plan detail at stair P-6 showing reduction in clearances; see photos on following page

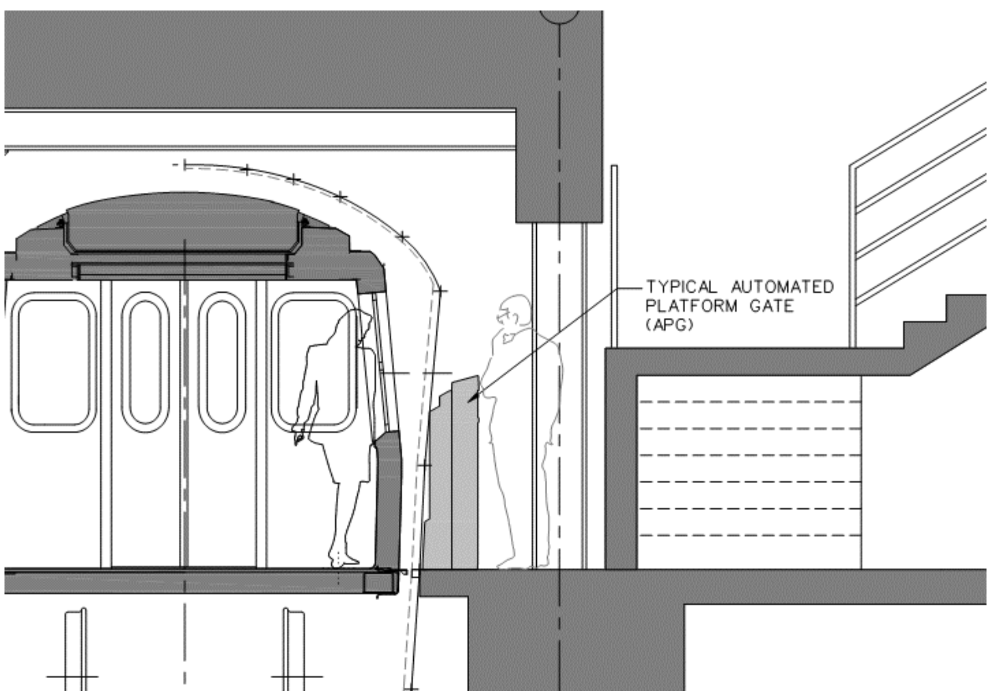

Figure 16 - Section at stair P-6, P-7 at Brooklyn-bound platform – 14th St / Union Square Station

Figure 17 - Brooklyn-bound platform at stair P-6 showing ADA train door – Union Square Station

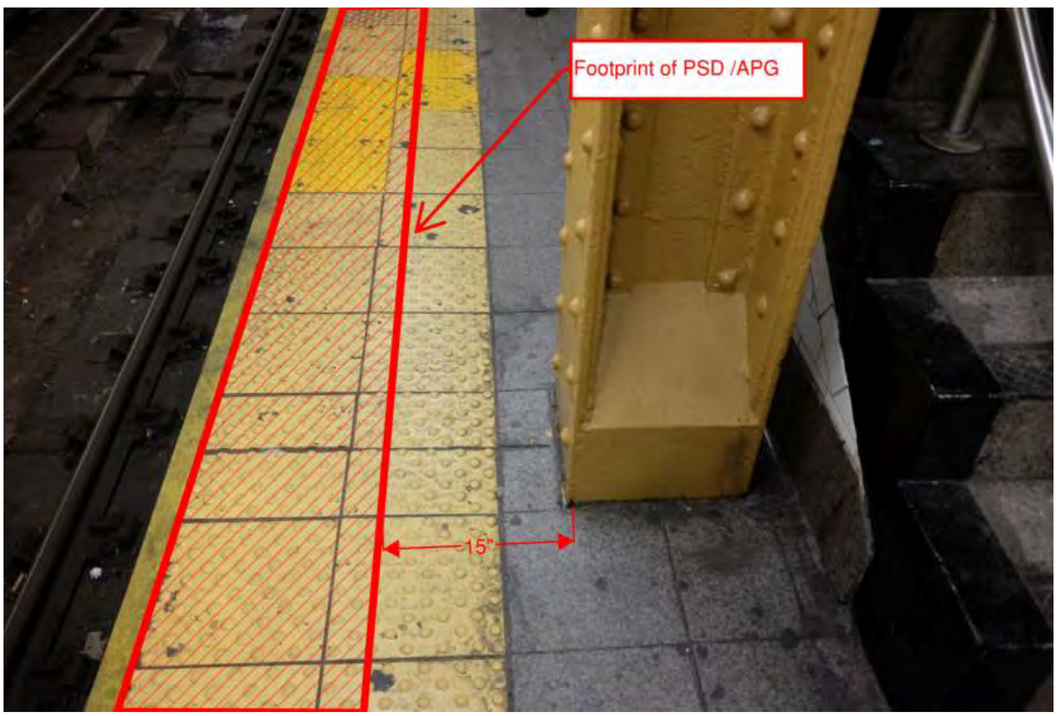

Figure 18 - Brooklyn-bound platform at stair P-7 – Union Square Station

6.3 3rd Avenue Station

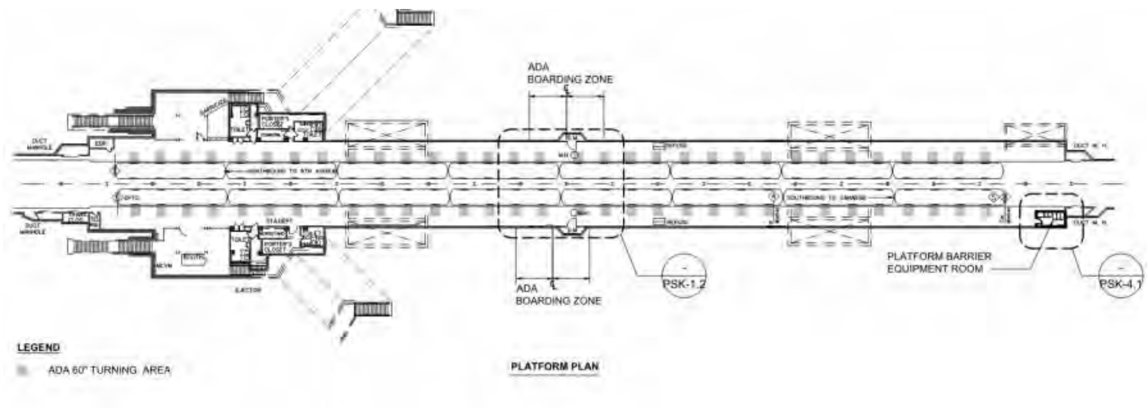

Figure 19 - Key Plan – 3rd Avenue Station

Equipment Room

Space required for equipment room is available at the end of the platform.

Track Layout

Track is tangent. No excessive gaps are anticipated.

Platform edge condition

Existing conditions: Retrofitted fiber reinforced polymer panels laid on top of existing concrete cantilever; orange abrasive strip with likely asbestos content. The 2012 NYCT condition survey report gave the platform edges a rating of 3.5. Platform structural work will be required.

Platform obstructions within 5' of edge:

Brooklyn Bound: no columns; no obstructions

8th Avenue Bound: no columns; no obstructions

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Not expected to be an issue if APGs are employed.

Ventilators:

Per the NYCT MOW drawings, two sets of ventilators are indicated over each platform.

Power:

Power is adequate. (see power summary)

Historic Restrictions:

None

Conclusion:

Due to the absence of platform columns or other obstructions, the 3rd Avenue Station is a good candidate for the pilot installation of platform barriers. The platform edge is tangent and plumb and the nearest obstruction (the platform wall) is 8'-9" away (in built condition). Furthermore, due to the light usage of the station, the risk factor of mechanical failure has a much lesser consequence than at the other two stations.

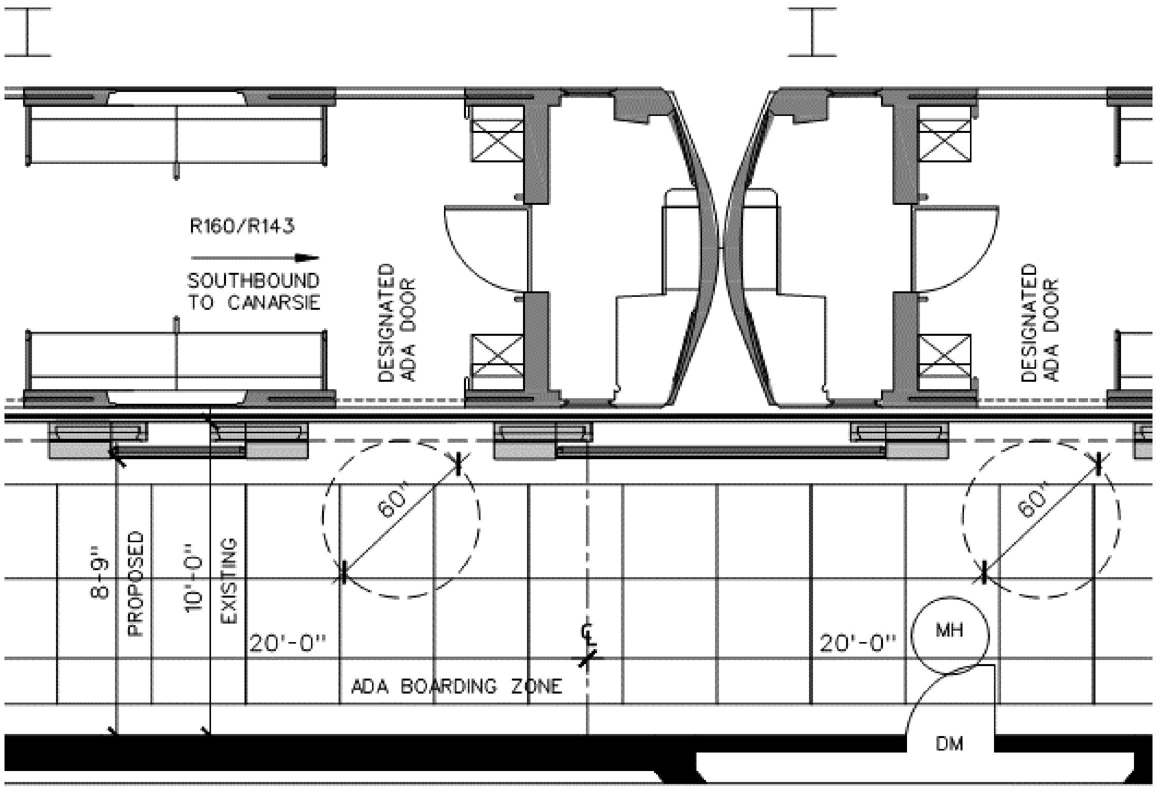

Figure 20 - Plan detail - 3rd Ave platform

Figure 21 - 3rd Avenue Platform

6.4 1st Avenue Station

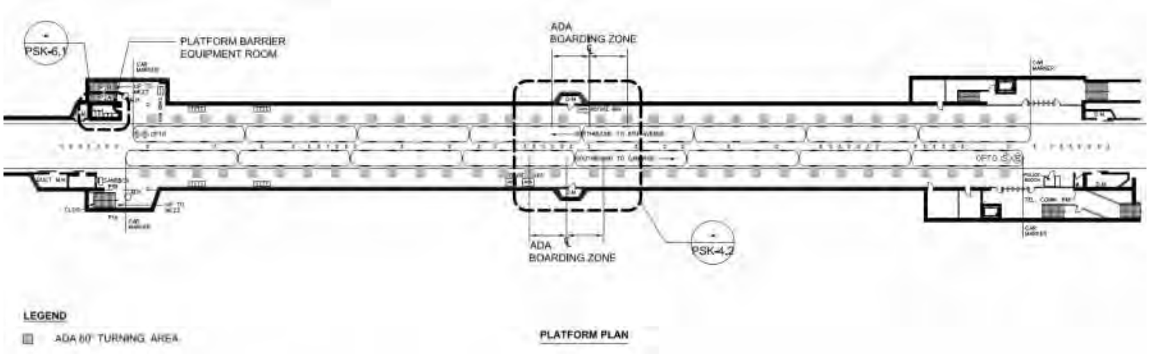

Figure 22 - Key Plan – 1st Avenue Station

Equipment Room

Space required for equipment room is potentially available at the end of the platform. However, the design of the First Avenue Station Rehabilitation (P-36437) indicates use of the abandoned EDR's as refuse rooms. There is no other readily available space for the equipment room.

Existing EDR-R room is to be decommissioned upon completion of contract P-36437. It will be required to make the room larger as necessary. However, per NYCT, existing EDR-R room will not be available until mid 2020.

Track Layout

Track is tangent. No excessive gaps are anticipated.

Platform edge condition

Existing conditions: Retrofitted fiber reinforced polymer panels laid on top of existing concrete cantilever; orange abrasive strip with likely asbestos content. The 2012 NYCT condition survey report gave the platform edges a rating of 3.0 for northbound and a rating of 3.5 for Southbound. Platform structural work will be required on both platforms to support the added load of the platform edge barrier.

Platform obstructions within 5' of edge:

Brooklyn Bound: no columns; no obstructions

8th Avenue Bound: no columns; no obstructions

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Not expected to be an issue if APGs are employed.

Ventilators:

Per site observation by STV, two sets of ventilators are present over Brooklyn bound platform. And three sets of ventilators are present over 8th Avenue bound platform.

Power:

The proposed new electrical 800 amp service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward. See power summary.

Historic Restrictions:

None

Conclusion:

Although 1st Avenue Station has no platform columns or other obstructions, it is not a recommended candidate for the installation of a pilot platform edge barrier. There are three primary reasons for this finding:

- Scheduling of contract P-36437 (First Ave. Rehab) indicates availability of the equipment room space in mid-2020. Therefore, installation of the equipment room will not be feasible until the completion and re-opening of the Canarsie tunnel project.
- In addition to the above constraint, installation of the platform doors will need to occur after major construction of the tunnel project, since the First Avenue station is the entry point for all construction materials. This will necessarily extend the timeline of closure for the Canarsie line.
- Electrical power upgrade will need to be altered to a higher capacity in order to accommodate PSD.

ESTIMATE DATE:	July 28, 2017

VJ ASSOCIATES
ORDER OF MAGNITUDE COSTS

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

MTA/NYCT

July 28, 2017

BASIS OF ESTIMATE

1.00 Asbestos-Containing Materials (ACM) costs are excluded from this estimate.

2.00 Work is to be carried out during normal working hours - all train operations will be stopped

3.00 Escalation is calculated at 5% per annum based on APG Procurement Design Installation Timeline

4.00 Estimate includes costs associated with ADA zone concrete.

5.00 Estimate does not include State of Good Repair

6.00 NYCT project cost is not included

7.00 GO and flagging cost is not included

8.00 Maintenance / Operational Costs are not included. These will form part of a separate exercise

9.00 *Description of typical APG / PSD installation:*

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

MTA/NYCT

July 28, 2017

BASIS OF ESTIMATE

9.0.1 *APGs / PSDs will provide 30 emergency egress doors with push bars per platform*

9.0.2 *APGs will be 4'-6" foot high system cantilevered from the platform*

9.0.3 *Each platform edge will have 8 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*

9.0.4 *Control Rooms will be 8 FT wide by 16 FT long and 8 FT tall; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls*

9.0.5 *Each Control Room will serve two platform edges*

9.0.6 *Control Rooms will be cooled to maintain operability of the control equipment*

9.0.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*

9.0.8 *Stray current isolation will be required* by *means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

9.0.9 *The existing platform edge lighting is to remain*

9.0.10 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

MTA/NYCT

July 28, 2017

BASIS OF ESTIMATE

9.1 ***Assumptions:***

9.1.1 *Two-foot wide platform edge finish and topping slab will be removed down to the structural slab and new granite tile/tactile warning tile will be installed on the platform side of the APGs (assumed width of finish on platform side of APGs is 1'-0")*

9.1.2 *All platforms will require structural rehabilitation to take APG loads*

9.1.3 *There are no special security requirements made necessary by installation of the APG system*

9.2 ***Exclusions - Costs not included in the estimate:***

9.2.1 *Costs associated with construction of remote Control Rooms (at locations other than inside the station)*

9.2.2 *Costs associated with changes to train signals or systems*

9.2.3 *Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length*

9.2.4 *Costs associated with NYCT State Of Good Repair improvements to the station*

9.2.5 *Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.*

BASIS OF ESTIMATE

9.2.6 *For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs*

9.3 ***Below the line or "soft" costs:***

9.3.1 *Design and Construction Contingency*
9.3.2 *Contractor O & P*
9.3.3 *Insurance*
9.3.4 *NYCT project costs not included*

9.5 ***Additional Notes***

9.5.1 *Given the limited time available, no drawings were developed to support this estimate.*

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

LOCATION: CANARSIE LINE

July 28, 2017

ORDER OF MAGNITUDE COSTS

	DESCRIPTION		3RD AVENUE	14TH ST / UNION SQ	6TH AVENUE
ADD ALTERNATIVES					
A	Additional cost associated with Platform Screen Doors [PSD's] in lieu of Automatic Platform Gates [APG's]		1,525,900	1,442,410	1,961,500
	Add for Markups (as above)	152.21%	2,322,612	2,195,530	2,985,651
			$3,848,512	$3,637,940	$4,947,151
B1	Additional cost associated with CBTC Berthing System in lieu of Wayside only system		2,229,912	2,229,912	2,229,912
	Add for Markups (as above)	152.21%	3,394,208	3,394,208	3,394,208
			$5,624,120	$5,624,120	$5,624,120
B2	Additional cost associated with Dedicated loop Berthing System in lieu of Wayside only system		2,603,028	2,603,028	2,603,028
	Add for Markups (as above)	152.21%	3,962,137	3,962,137	3,962,137
			$6,565,165	$6,565,165	$6,565,165

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

28-Jul-17

STATION: 3RD AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 106 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4					
5	TOTAL LENGTH OF THE PLATFORM EDGE = 530' x 2 No. EDGES	1,060	LF		
6					
7	AUTOMATIC PLATFORM GATES [APG's]				
8					
9	NEW WORK				
10					
11	REBUILD CONCRETE EDGE				
12	Remove existing tatile warning strip 2' wide	1,060	LF	$15.00	15,900
13	Remove existing polyethylene edge strip	1,060	LF	$7.00	7,420
14	Remove and construct Reinforced concrete edge 9" wide	1,060	LF	$250.00	265,000
15	Tactile warning strip 2' wide	2,120	SF	$110.00	233,200
16	Polyethylene edge strip	1,060	LF	$95.00	100,700
17	Misc. patchwork	1	LS	$50,000.00	50,000
18					
19	Automatic Platform Gates [APGs] - 4'-6" High				
20	Automatic bi-parting gates; Assumed 6'-0" wide (8 Cars x 4 Doors = 32 No. per platform)	64	EA	$15,000.00	960,000

STATION: 3RD AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
21	Glass fence including framing and support; 4'-6" High	3,042	SF	$750.00	2,281,500
22	"Extra over" above for push bar operated emergency egress gates; single swing hinged (Allow 30 no. per platform)	60	EA	$3,500.00	210,000
23	Allow for conduit / cable runs for power and communications under platform edge	1,060	LF	$60.00	63,600
24	Allowance for Braille Signage	64	EA	$2,500.00	160,000
25	Testing and commissioning	500	HRS	$152.43	76,215
26					
27	CCTV coverage				
28	Cameras [8 No. per platform]	16	EA	$2,000.00	32,000
29	Application Access Node	3	EA	$20,000.00	60,000
30	Conduit to wireway	240	LF	$20.00	4,800
31	Wire from cameras to the new Application Access Node in the area	800	LF	$10.00	8,000
32	Connection Application Acces Node to existing Access Node	2	EA	$2,000.00	4,000
33					
34	Communication / Control Room [8'-0" x 16'-0"]				
35	CMU Wall for control room	384	SF	$45.00	17,280
36	Door including frame & hardware	1	EA	$1,800.00	1,800
37	Glazed Ceramic Wall on Exterior (4 side of Wall)	384	SF	$35.00	13,440
38	Interior Wall Finishes	384	SF	$5.00	1,920
39	Construct Ceiling at Control Room	128	SF	$20.00	2,560
40	Provision of Cooling System	1	LS	$7,500.00	7,500
41	Allow for Electrical Work inside Control Room	1	LS	$10,000.00	10,000
42	Allow for Misc. Floor & ceiling finishes	128	SF	$15.00	1,920
43	Allowance to bring power to Control Room from EDR [Full length of platform]	530	LF	$60.00	31,800
44	Allowance for power to cross tracks to opposite platform	1	LS	$15,000.00	15,000
45	Allowance to bring fiber optic to Control Room from network node	1	LS	$15,000.00	15,000
46					
47	Berthing Technology				

Study for the installation of PSD's at selected station on the Canarsie Line - 3rd Avenue, 14th Street / Union Square or 6th Avenue

28-Jul-17

STATION: 3RD AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
48	Allowance for Berthing Technology for Control Train Berthing				
49	Allowance for "Wayside Only" berthing system as per "Berthing Control System Comparison" Report	1	LS	$732,000.00	732,000
50					
51	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.				
52	System-wide Cost [expressed as a cost per station i.e. 1/620 or 0.16%]	0.16%	LS	$1,500,000.00	2,419
53					
54	Entrapment concerns				
55	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	192	EA	$4,629.24	888,814
56	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	192	EA	$4,877.76	936,530
57					
58	Grounding				
59	Allowance for new grounding wiring for structural steel throughout station	1	LS	$30,000.00	30,000
60					
61	Platform edge lighting				
62	No allowance for new lighting		Note		EXCL.
63					
64	Electrical Upgrades				
65	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
66					
67	Structural Rehabilitation

ORDER OF MAGNITUDE COSTS

STUDY FOR THE INSTALLATION OF PSD'S AT SELECTED STATION ON THE CANARSIE LINE - 1ST AVENUE STATION

MTA/NYCT

September 14, 2017

BASIS OF ESTIMATE

1.00 Asbestos-Containing Materials (ACM) costs are excluded from this estimate.

2.00 Work is to be carried out during normal working hours - all train operations will be stopped

3.00 Escalation is calculated at 5% per annum based on APG Procurement Design Installation Timeline

4.00 Estimate includes costs associated with ADA zone concrete.

5.00 Estimate does not include State of Good Repair

6.00 NYCT project cost is not included

7.00 GO and flagging cost is not included

8.00 Maintenance / Operational Costs are not included. These will form part of a separate exercise

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

STUDY FOR THE INSTALLATION OF PSD'S AT SELECTED STATION ON THE CANARSIE LINE - 1ST AVENUE STATION

MTA/NYCT

September 14, 2017

BASIS OF ESTIMATE

9.00 ***Description of typical APG / PSD installation:***

9.0.1 *APGs / PSDs will provide 30 emergency egress doors with push bars per platform*
9.0.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
9.0.3 *Each platform edge will have 8 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
9.0.4 *Control Rooms will be 8 FT wide by 16 FT long and 8 FT tall; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls*
9.0.5 *Each Control Room will serve two platform edges*
9.0.6 *Control Rooms will be cooled to maintain operability of the control equipment*
9.0.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
9.0.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

9.0.9 *The existing platform edge lighting is to remain*
9.0.10 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

STUDY FOR THE INSTALLATION OF PSD'S AT SELECTED STATION ON THE CANARSIE LINE - 1ST AVENUE STATION

MTA/NYCT

September 14, 2017

BASIS OF ESTIMATE

9.1 ***Assumptions:***

9.1.1 *Two-foot wide platform edge finish and topping slab will be removed down to the structural slab and new granite tile/tactile warning tile will be installed on the platform side of the APGs (assumed width of finish on platform side of APGs is 1'-0")*

9.1.2 *All platforms will require structural rehabilitation to take APG loads*

9.1.3 *There are no special security requirements made necessary by installation of the APG system*

9.2 ***Exclusions - Costs not included in the estimate:***

9.2.1 *Costs associated with construction of remote Control Rooms (at locations other than inside the station)*

9.2.2 *Costs associated with changes to train signals or systems*

9.2.3 *Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length*

9.2.4 *Costs associated with NYCT State Of Good Repair improvements to the station*

9.2.5 *Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.*

BASIS OF ESTIMATE

9.2.6 *For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs*

9.3 ***Below the line or "soft" costs:***

9.3.1 *Design and Construction Contingency*
9.3.2 *Contractor O & P*
9.3.3 *Insurance*
9.3.4 *NYCT project costs not included*

9.5 ***Additional Notes***

9.5.1 *Given the limited time available, no drawings were developed to support this estimate.*

STUDY FOR THE INSTALLATION OF PSD'S AT SELECTED STATION ON THE CANARSIE LINE - 1ST AVENUE STATION

14-Sep-17

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 106 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4					
5	TOTAL LENGTH OF THE PLATFORM EDGE = 500' [EDGE 01] + 505' [EDGE 02] =	1,005	LF		
6

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

MTA/NYCT

June 22, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs / PSDs will provide 32 emergency egress doors with push bars per platform*
1.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.2 In respect of the PSD option, only platforms that have not been upgraded in the recent past (assuming over the past two decades) will require platform edge replacement.
2.3 There are no special security requirements made necessary by installation of the APG system
2.4 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.5 This estimate does not provide for the replacement of Platform Edge Lighting
2.6 Premium cost for night time work is considered 50% of total labor cost

VJ ASSOCIATES

ORDER OF MAGNITUDE COSTS

A CONSTRUCTION CONSULTING FIRM

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

MTA/NYCT

June 22, 2018

BASIS OF ESTIMATE

3.0 *Exclusions - Costs not included in the estimate:*

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 *Below the line or "soft" costs:*

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 *Additional Notes*

5.1 *Given the limited time available, no drawings were developed to support this estimate.*

STATION: 8TH AVENUE

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200
24	Remove existing platform tiles	1,080	LF	12	12,960
25	Sawcut existing topping concrete at perimeter of removal area	1,080	LF	5	5,400
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,480	SF	8	51,840
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 20' wide strip at ADA boarding area	1,120	SF	8	8,960
28	New Work				
29	New concrete topping to match existing	1,080	SF	15	16,200
30	New concrete topping at ADA boarding area to match existing	1,120	SF	15	16,800
31	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
32	Misc. patchwork	1	LS	50,000	50,000
33					
34	Equipment Room [8'-0" x 30'-0"]				
35	Build off existing platform slab		Note		
36	Form 8" wide concrete curb including dowelling to platform slab	46	LF	90	4,140
37	CMU Wall for equipment room	460	SF	45	20,700
38	Vertical connections with existing structure	20	LF	25	500
39	Fire rated door including frame & hardware	1	EA	2,500	2,500
40	Exterior wall finish				

STATION: 8TH AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
41	Ceramic Tiling to match existing	460	SF	40	18,400
42	Mosaic Band to match existing - Assuming 8" high	46	LF	120	5,520
43	Concrete cove to match existing	46	LF	20	920
44	Interior Wall Finish - Paint	460	SF	5	2,300
45	Allow for Misc. floor & ceiling finishes	240	SF	15	3,600
46	Allow for 4" thick concrete pads for equipment	60	SF	20	1,200
47	Allowance for Mechanical Scope	1	LS	40,000	40,000
48	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
49	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
50	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
52	Automatic Platform Gates [APGs] - 4'-6" High				
53	Automatic bi-parting gates; Assumed 6'-0" wide (8 Cars x 4 Doors = 32 No. per platform)	64	EA	15,000	960,000
54	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #30 per Platform	60	EA	10,500	630,000
55	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
56	Platform End Gates (PEGs)	4	EA	13,000	52,000
57	Fixed Panels including framing and support; 4'-6" High	2,250	SF	750	1,687,500
58	Spare Parts - Approx. 10% of Material Cost	1	LS	202,170	202,170
59	Testing and commissioning	800	HRS	160	127,944
60	Product Warranty	1	LS	1,000,000	1,000,000
61	Allowance for Braille Signage	64	EA	2,500	160,000
62					
63	Electrical				
64	Electrical Upgrades				
65	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
66	Power and Lighting				
67	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
68	Allow for conduit / cable runs for power and communications under platform edge	1,080	LF	60	64,800
	PSD Connections	1	LS	75,000	75,000
70	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
71	Power to PSD Room from EDR including track crossing if needed	500	LF	60	30,000
72	Reserve power to PSD Room from EDR including track crossing if needed	500	LF	60	30,000
73	Reference Tier 2/3 Report [Page 1 of 9], No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
74	Grounding				
75	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
76	MISC				
77	Testing and commissioning	1	LS	30,000	30,000
78	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000
79					
80	Communications				
81	FA System				
82	Scope in connection with Fire Alarm System	1	LS	100,000	100,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

22-Jun-18

STATION: 8TH AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
83	CCTV coverage				
84	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
85	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
86	Berthing Technology Sensors				
87	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	8	EA	16,000	128,000
88	Train Door Detection System				
89	Train Door Detection Sensor including software and hardware requirements	8	EA	15,000	120,000
90	Entrapment concerns				
91	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	192	EA	4,629	888,814
92	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	192	EA	5,566	1,068,588
93	Engineering and Testing	2,000	Hrs	160	319,860
94	Centralized monitoring/control				
95	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
96	MISC				
97	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

22-Jun-18

STATION: 1ST AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	500	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	505	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,005	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,005	LF	7	7,035
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,025	SF	12	60,300
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	94	CY	2,500	235,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,014	EA	25	50,350
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,005	LF	95	95,475
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,005	LF	15	15,075
24	Remove existing platform tiles	1,005	LF	12	12,060
25	Sawcut existing topping concrete at perimeter of removal area	1,005	LF	5	5,025
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,030	SF	8	48,240
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 20' wide strip at ADA boarding area	1,120	SF	8	8,960
28	New Work				
29	New concrete topping to match existing	1,005	SF	15	15,075
30	New concrete topping at ADA boarding area to match existing	1,120	SF	15	16,800
31	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
32	Misc. patchwork	1	LS	50,000	50,000
33					
34	Equipment Room [8'-0" x 30'-0"]

STATION: GRAHAM AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200
24	Remove existing platform tiles	1,080	LF	12	12,960
25	Sawcut existing topping concrete at perimeter of removal area	1,080	LF	5	5,400
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,480	SF	8	51,840
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 9'-10" and 9'-11" wide strip	316	SF	8	2,528
28	New Work				
29	New concrete topping to match existing	1,080	SF	15	16,200
30	New concrete topping at ADA boarding area to match existing	316	SF	15	4,740
31	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
32	Misc. patchwork	1	LS	50,000	50,000
33					
34	Equipment Room				
35	Manhattan Bound [7'-0" x 17'-0"]				
36	Build off existing platform slab		Note		
37	Form 8" wide concrete curb including dowelling to platform slab	31	LF	90	2,790
38	CMU Wall for equipment room	310	SF	45	13,950
39	Vertical connections with existing structure	20	LF	25	500
40	Fire rated door including frame & hardware	1	EA	2,500	2,500
41	Exterior wall finish

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

22-Jun-18

STATION: HALSEY AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200
24	Remove existing platform tiles	1,080	LF	12	12,960
25	Sawcut existing topping concrete at perimeter of removal area	1,080	LF	5	5,400
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,480	SF	8	51,840
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12' wide strip	480	SF	8	3,840
28	New Work				
29	New concrete topping to match existing	1,080	SF	15	16,200
30	New concrete topping at ADA boarding area to match existing	480	SF	15	7,200
31	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
32	Misc. patchwork	1	LS	50,000	50,000
33					
34	Equipment Room [12'-0" x 16'-0"]				
35	Build off existing platform slab		Note		
36	Form 8" wide concrete curb including dowelling to platform slab	40	LF	90	3,600
37	CMU Wall for equipment room	400	SF	45	18,000
38	Vertical connections with existing structure	20	LF	25	500
39	Fire rated door including frame & hardware	1	EA	2,500	2,500
40	Exterior wall finish				
41	Ceramic Tiling to match existing	400	SF	40	16,000

STATION: HALSEY AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
42	Mosaic Band to match existing - Assuming 8" high	40	LF	120	4,800
43	Concrete cove to match existing	40	LF	20	800
44	Interior Wall Finish - Paint	400	SF	5	2,000
45	Allow for Misc. floor & ceiling finishes	192	SF	15	2,880
46	Allow for 4" thick concrete pads for equipment	48	SF	20	960
47	Allowance for Mechanical Scope	1	LS	40,000	40,000
48	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
49	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
50	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
52	**Automatic Platform Gates [APGs] - 4'-6" High**				
53	Automatic bi-parting gates; Assumed 6'-0" wide (8 Cars x 4 Doors = 32 No. per platform)	64	EA	15,000	960,000
54	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #30 per Platform	60	EA	10,500	630,000
55	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
56	Platform End Gates (PEGs)	4	EA	13,000	52,000
57	Fixed Panels including framing and support; 4'-6" High	2,250	SF	750	1,687,500
58	Spare Parts - Approx. 10% of Material Cost	1	LS	202,170	202,170
59	Testing and commissioning	800	HRS	160	127,944
60	Product Warranty	1	LS	1,000,000	1,000,000
61	Allowance for Braille Signage	64	EA	2,500	160,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'L' (Canarsie) Line Stations in Brooklyn

22-Jun-18

STATION: BUSHWICK AVE - ABERDEEN STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200
24	Remove existing platform tiles	1,080	LF	12	12,960
25	Sawcut existing topping concrete at perimeter of removal area	1,080	LF	5	5,400
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,480	SF	8	51,840
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12' wide strip	480	SF	8	3,840
28	New Work				
29	New concrete topping to match existing	1,080	SF	15	16,200
30	New concrete topping at ADA boarding area to match existing	480	SF	15	7,200
31	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
32	Misc. patchwork	1	LS	50,000	50,000

STATION: BROADWAY JUNCTION

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	540	LF		
5	LENGTH OF THE PLATFORM EDGE [CANARSIE BOUND] =	540	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,080	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,080	LF	7	7,560
13	Remove 5' wide section of 3" deep structural slab to platform edge	5,400	SF	12	64,800
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	100	CY	2,500	250,000
16	Pair of dowels (front & rear) cast into existing at 12" O.C	2,164	EA	25	54,100
17	Cast in assemblies for PSD holding down bolts	512	EA	180	92,160
18	Polyethylene edge strip	1,080	LF	95	102,600
19	Provide sleeves for HV & LV wires	256	EA	110	28,160
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	1,080	LF	15	16,200
24	Remove existing platform tiles	1,080	LF	12	12,960
25	Sawcut existing topping concrete at perimeter of removal area	1,080	LF	5	5,400
26	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,480	SF	8	51,840
27	Remove existing 3" concrete topping at 40' long ADA boarding area; Assume balance of Manhattan bound platform width i.e. 20' wide strip at ADA boarding area	560	SF	8	4,480
28	Remove existing 3" concrete topping at 40' long ADA boarding area; Assume balance of Canarsie bound platform width i.e. 19' wide strip at ADA boarding area	520	SF	8	4,160
29	New Work				
30	New concrete topping to match existing	1,080	SF	15	16,200
31	New concrete topping at ADA boarding area to match existing	560	SF	15	8,400
32	Tactile Warning Strip - 2' wide strip along platform edge at door openings only (#32) & Platform end gates	384	LF	110	42,240
33	Misc. patchwork	1	LS	50,000	50,000
34					
35	Equipment Room [12'-0" x 16'-0"]				
36	Build off existing platform slab		Note		
37	Form 8" wide concrete curb including dowelling to platform slab	40	LF	90	3,600
38	CMU Wall for equipment room	400	SF	45	18,000

STATION: BROADWAY JUNCTION

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
39	Vertical connections with existing structure	20	LF	25	500
40	Fire rated door including frame & hardware	1	EA	2,500	2,500
41	Exterior wall finish				
42	Ceramic Tiling to match existing	400	SF	40	16,000
43	Mosaic Band to match existing - Assuming 8" high	40	LF	120	4,800
44	Concrete cove to match existing	40	LF	20	800
45	Interior Wall Finish - Paint	400	SF	5	2,000
46	Allow for Misc. floor & ceiling finishes	192	SF	15	2,880
47	Allow for 4" thick concrete pads for equipment	48	SF	20	960
48	Allowance for Mechanical Scope	1	LS	40,000	40,000
49	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
50	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
51	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
53	**Automatic Platform Gates [APGs] - 4'-6" High**				
54	Automatic bi-parting gates; Assumed 6'-0" wide (8 Cars x 4 Doors = 32 No. per platform)	64	EA	15,000	960,000
55	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #30 per Platform	60	EA	10,500	630,000
56	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
57	Platform End Gates (PEGs)	4	EA	13,000	52,000
58	Fixed Panels including framing and support; 4'-6" High	2,250	SF	750	1,687,500
59	Spare Parts - Approx. 10% of Material Cost	1	LS	202,170	202,170
60	Testing and commissioning	800	HRS	160	127,944
61	Product Warranty	1	LS	1,000,000	1,000,000
62	Allowance for Braille Signage	64	EA	2,500	160,000
63					
64	**Electrical**				
65	Electrical Upgrades				
66	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
67	Power and Lighting				
68	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000
69	Allow for conduit / cable runs for power and communications under platform edge	1,080	LF	60	64,800
	PSD Connections	1	LS	75,000	75,000
71	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	200,000	200,000
72	Power to PSD Room from EDR including track crossing if needed	400	LF	60	24,000
73	Reserve power to PSD Room from EDR including track crossing if needed	400	LF	60	24,000
74	Reference Tier 2/3 Report [Page 1 of 9], No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
75	Grounding				
76	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	30,000	30,000
77	MISC				
78	Testing and commissioning	1	LS	30,000	30,000
79	As Built, Shop Drwgs, Permits and approvals	1	LS	20,000	20,000

	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 2) [DEFAULT OPTION AS PER RFP DOCUMENTATION]		TOTAL:	$ 6,078,826	$ 6,078,826	$ 7,619,663
	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 1)		TOTAL:	$ 7,619,663		

ITEM NO.	DESCRIPTION		RATE	
7	Labor Bill Rate (per hour)	Year 1	$ 238 per hour *	
	Task Orders (Rate in Effect 24/7/365)	Year 2	$ 248 per hour *	
		Year 3	$ 257 per hour *	
	Optional :	Year 4	$ 268 per hour *	
	Optional :	Year 5	$ 278 per hour *	

Note: Labor rate is deemed to include all relevant tax and insurance, medical, pension, vacation fund, etc., travel time to and from project site and night/shift/weekend/holiday work i.e. 24/7 Rate

* Labor rates include Contractor's Overhead & Profit and Insurance (Refer Annual Maintenance Cost Breakdown) and are escalated at 4% per annum

MTA New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'N' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: January 31, 2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 46 evaluated stations, 36 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Stations are found to be infeasible where these PSDs:
  - Limit the ability of a wheelchair to turn a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at the N line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 22% of the 'N' Line stations. Total implementation cost would be $318.9M for APGs and $363.5M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 10 feasible stations, the aggregate annual maintenance cost would be $9.3M.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'N' Line Stations

Summary Table

N Service Summary of Feasibility					(22% Feasible 10 / 46)		
MRN No.	**Station Names**	**Station Type**	**Platform Type**	**Feasibility**	**Issues/Reason for Failure**	**Cost APGs**	**Cost PSDs**

1.0 Station Assessments

1.01 – MR 001 | Astoria Ditmars Boulevard Station

Summary: *Astoria Ditmars Boulevard Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

Astoria Ditmars Boulevard Station is an elevated station consisting of a center / island platform. The platform structure is precast concrete. The width of the platform is 15'-0" throughout. There are two staircases at the center of the platform. The platform is straight with two rows of a columns supporting the station canopy. Column faces measure 3'-0" from the platform edge throughout. The canopy covers the center third of the platform. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Astoria Ditmars Boulevard Station

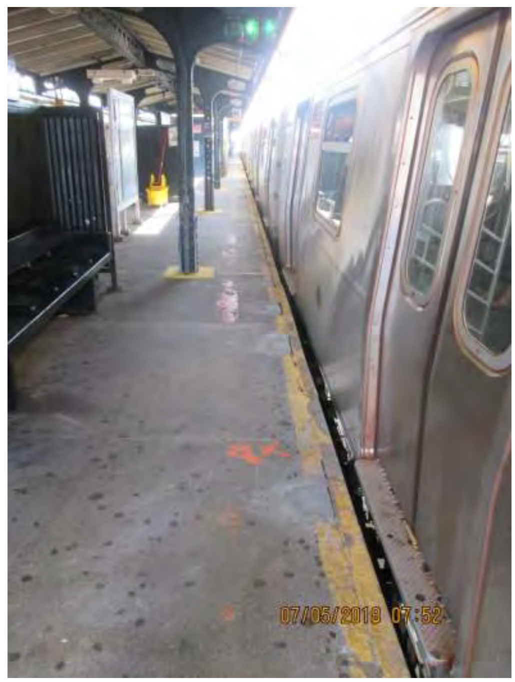

Figure 2 *– Precast Slab Seams*
Astoria Ditmars Boulevard Station

1.02 – MR 002 | Astoria Boulevard Station

__Summary:__ Astoria Boulevard Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).

Description

Astoria Boulevard Station is an elevated station with two center / island platforms. The platform structures are precast concrete. The width of the platforms is 17'-8" throughout. There are two staircases at the center of the platforms. The platforms are straight with two rows of a columns supporting their respective station canopies. Column faces measure 3'-4" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
Astoria Boulevard Station

***Figure 2** – Precast Slab*
Astoria Boulevard Station

1.03 – MR 003 | 30th Avenue Station

Summary: *30th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

30th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-0", narrowing to 8'-2" at the south ends. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies. Column faces measure 3'-0" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

Figure 1 *– Overall view*
30th Avenue Station

Figure 2 *– Precast concrete platforms*
30th Avenue Station

1.04 – MR 004 | Broadway Station

Summary: *Broadway Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

Broadway Station is an elevated station with two straight side platforms. The platform structures are precast concrete. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies the canopies cover approximately half of the platforms.

NOTE: Station specific dimensions and photographs could not be obtained at the time of this report due to station closure for rehabilitation.

Table of Contents

1.05 – MR 005 | 36th Avenue Station

***Summary:** 36th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

36th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-0. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies. Column faces measure 4'-0" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

***Figure 1** – Overall view*
36th Avenue Station

***Figure 2** – Precast concrete platforms*
36th Avenue Station

n

1.06 – MR 006 | 39th Avenue Station

Summary: *39th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

39th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies the canopies cover approximately half of the platforms.

NOTE: Station specific dimensions and photographs could not be obtained at the time of this report due to station closure for rehabilitation.

1.07 – MR 007 | Lexington Avenue / 59th Street Station

Summary: *Lexington Avenue / 59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all obstructions as the remaining width would be 30" (see figure 1).*

Description

Lexington Avenue / 59th Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 20'-0" throughout. Columns are spaced 15' on center with column faces 4'-0" away from the platform edges. The walls at the end of platform are 45" from the platform edge. The implementation of a platform edge barrier would reduce this width to 30" or less* which would not allow for ADA compliant wheelchair movement. Please see **figure 1** for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

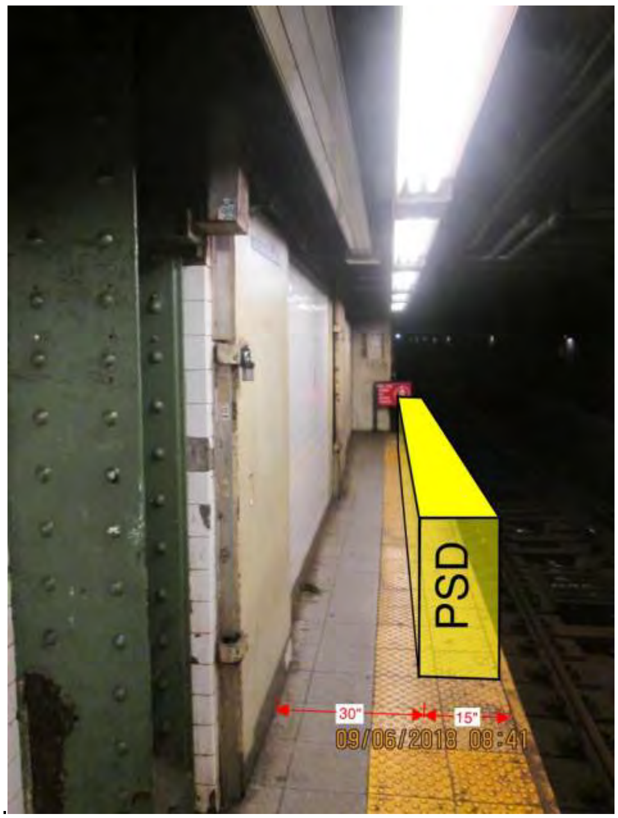

***Figure 1** – Non-Compliant ADA condition*
Lexington 59th Street Station

1.08 – MR 008 | Fifth Avenue / 59th Street Station

Summary: *Fifth Avenue / 59th Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at the center of each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Fifth Avenue / 59th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound platform width is approximately 11'-10" throughout. The northbound platform width is approximately 11'-6" throughout. At the center of each platform there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs. **(see Figure 3)**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located at the west mezzanine flush to the wall (see **Figure 1, Figure 2**). The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in 1995. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required only for the installation of an APG system.

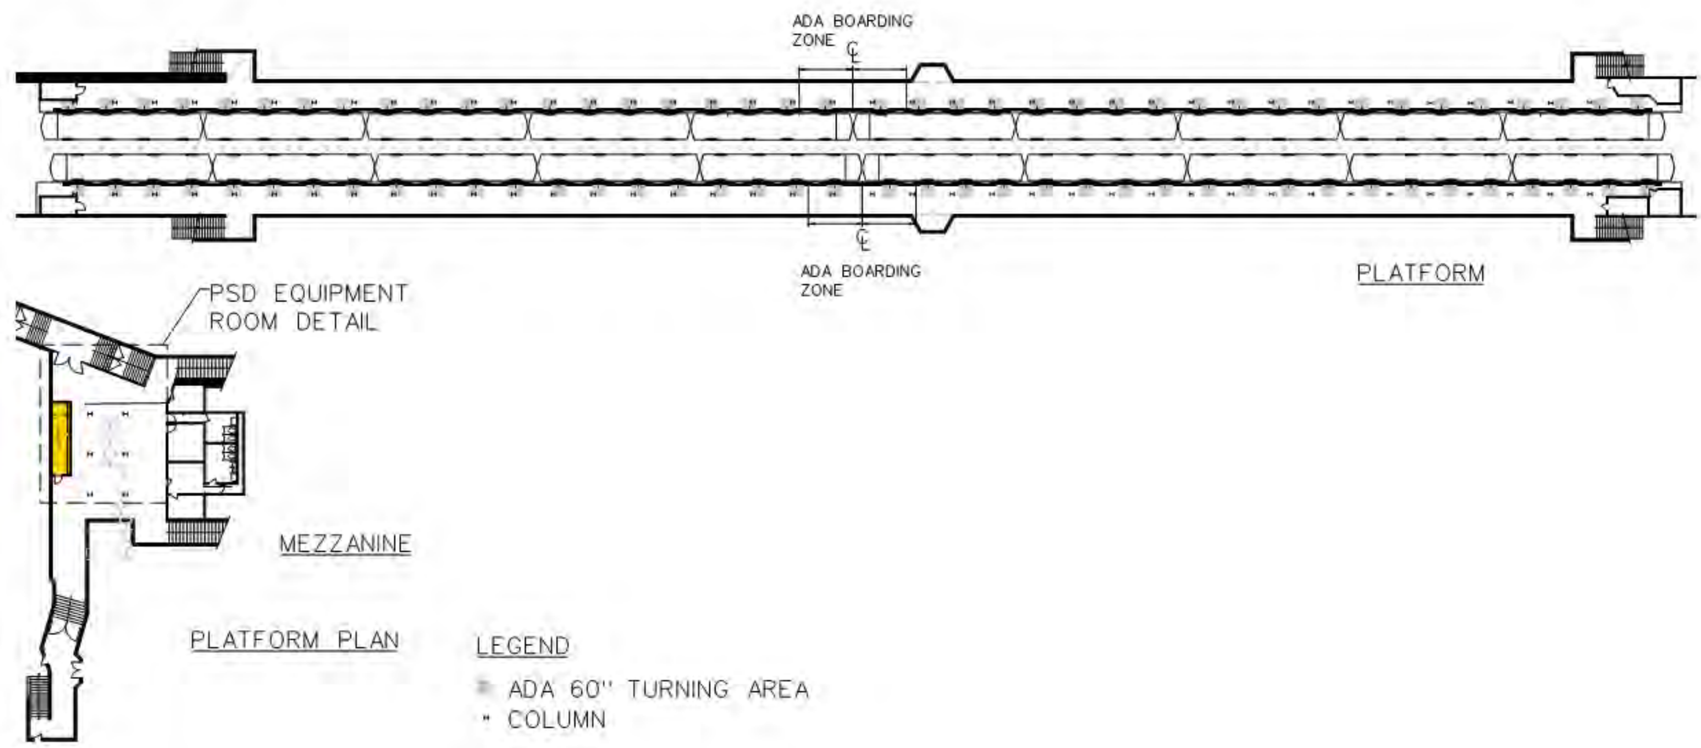

***Figure 1** – Overall Station Plan*
Fifth Avenue Station

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'N' Line Stations
(Fifth Avenue / 59th Street Station)

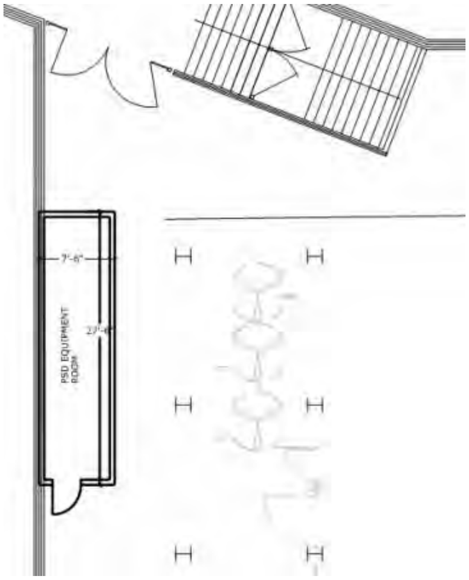

Figure 2 *– PSD Equipment Room Detail*
Fifth Avenue Station

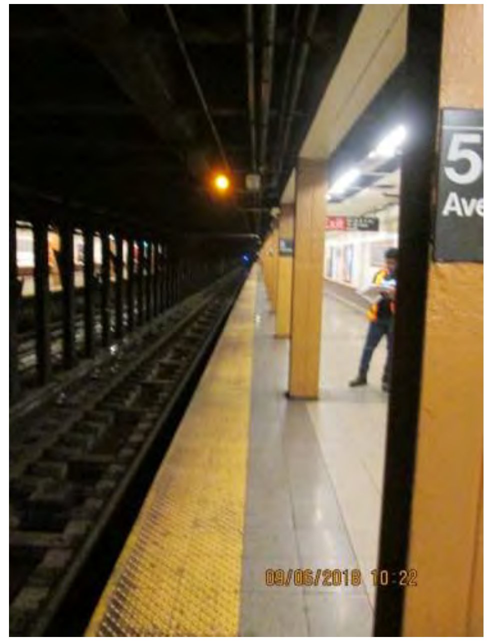

Figure 3 *– Signal above platform edge*
Fifth Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $31.2M to install APGs and $40.0M to install PSDs (See Appendix E)

***Figure 4** – Typical Platform View*
Fifth Avenue Station

Table of Contents

1.09 – MR 009 | 57th Street 7th Avenue Station

Summary: *57th Street 7th Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the center stairs as the remaining width would be 27" (see figure 1).*

Description

The 57th Street Station is an underground station consisting of two center / island platforms. The platforms are approximately 19'-8" wide. The platforms are straight with two rows of columns at 42" from the edge of the platform. At four staircases columns flank the stair. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA dimension*
57th Street Station

1.10 – MR 010 | 49th Street Station

Summary: *49th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). The existing power supply is adequate.*

Description

The 49th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns on the platforms. The platform width varies from approximately 7'-0" to 14'-8". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located as a split room, with one at the south control area of the southbound, and one located at the north control area of the southbound. (see **Figure 1, Figure 2**). The proposed room dimension is 16'-0" x 7'-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in 1995. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required only for the installation of an APG system.

(49th Street Station)

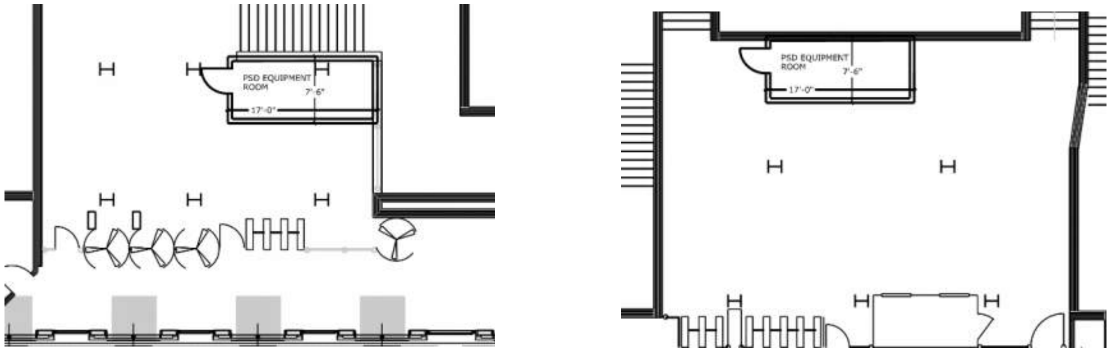

***Figure 2** – PSD Equipment Room Detail*
49th Street Station

Platform obstructions within 5' of edge:

None

Lighting:

Existing lighting: Throughout both platforms there are linear fluorescent fixtures mounted perpendicular to the platform edge in the ceiling coffers. No lighting reconfiguration will be required as part of a PSD installation.

***Figure 3** – General platform view*
49th Street Station

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	49th Street
Peak Demand Load from ConEd Report, Last **12** Months, (kW)	45.2
Apparent Power (kVA)	56.5
Station Peak Demand Load, Max Current, (A)	156.9
Maximum Number of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	352
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	449
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1-line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**. Meter reading is for 12 months.

Apparent Power (kVA)	34.0
Station Peak Demand Load, Max Current, (A)	94.5
Maximum Number of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	289
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	511
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1-line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Reserve service**. Meter reading is for 12 months.

Table 2. Power Capacity Analysis (Reserve)

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $33.5M to install APGs and $43.5M to install PSDs (See Appendix E)

1.11 – MR 011 | Times Square / 42nd Street Station

Summary: *Times Square / 42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 19" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the Shuttle, 7, 1,2,3-line for the remainder of the station)*

Description

Times Square / 42nd Street Station is a below-grade station consisting of two center / island platforms. The platform width is 19-4" throughout. The platforms are straight with two rows of columns at 3'-8" from edge of platform. At the south end of the platforms, the columns flanking an equipment room are 2'-10" from the platform edge. The implementation of a platform edge barrier would reduce this width to 19"or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

Figure 1 *–platform*
42nd Street / Times Square Station

Table of Contents

1.12 – MR 012 | 34th Street / Herald Square Station

Summary: *34th Street / Herald Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see the B, D, F, M-line report for the remainder of the station)*

Description

34th Street / Herald Square Station is a below-grade station consisting of two center / island platforms. The platform width is 19-8" throughout. The platforms are straight with two rows of columns at 3'-4" from edge of platform. On the center / island platform the columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

Figure 1 *–platform*
34th Street Station

1.13 – MR 013 | 28th Street Station

Summary: *28th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

28th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-6" from the platform edge at each platform, though approximately one third of the platform is column-free. The platform width varies from 6'-0" to 9'-5. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar..

.

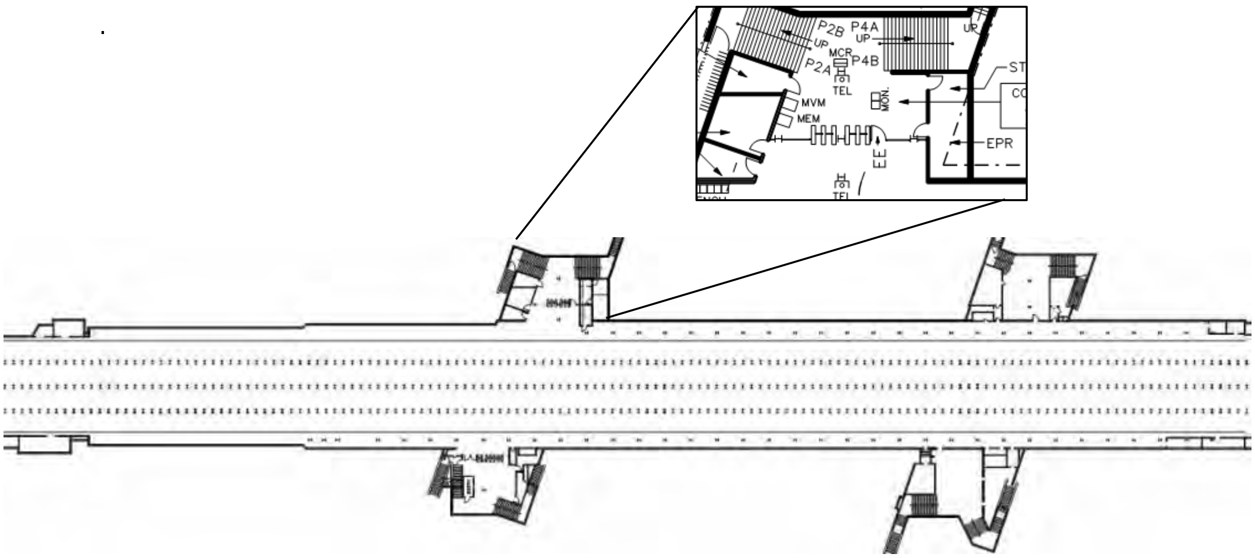

***Figure 1** – Station Plan- 28th Street Station*

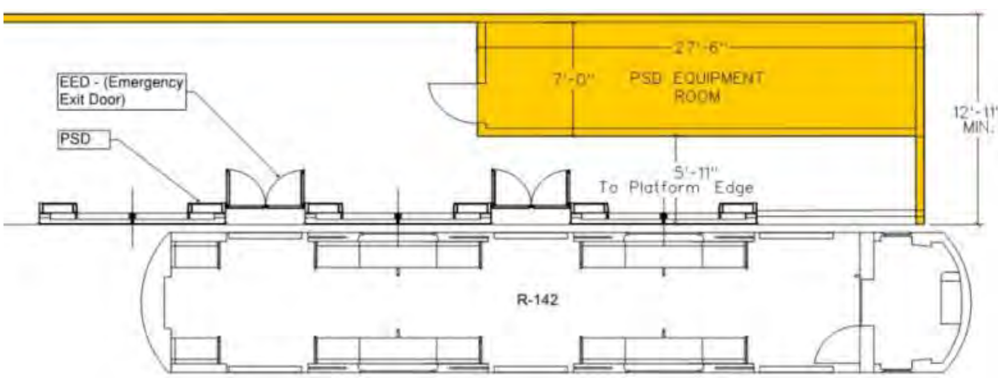

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.14 – MR 014 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound platform control area as the remaining width would be 27" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-8" from the platform edge at each platform. The platform width varies from 6'-0" to 11'-2" in width. The entry / exit turnstiles at the south entrance of the northbound platform are positioned with minimal clearance of 18" to the adjacent columns. The remaining space between the columns and the platform edge measures 42". The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figures 1and 2 below. The plan in figure 1 demonstrates that there is no alternative location for the turnstiles / railings.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

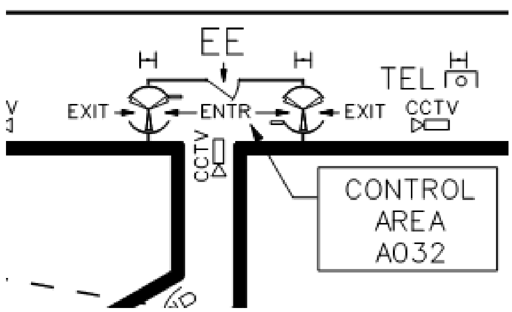

***Figure 1** – Non-Compliant ADA condition - 23rd Street*

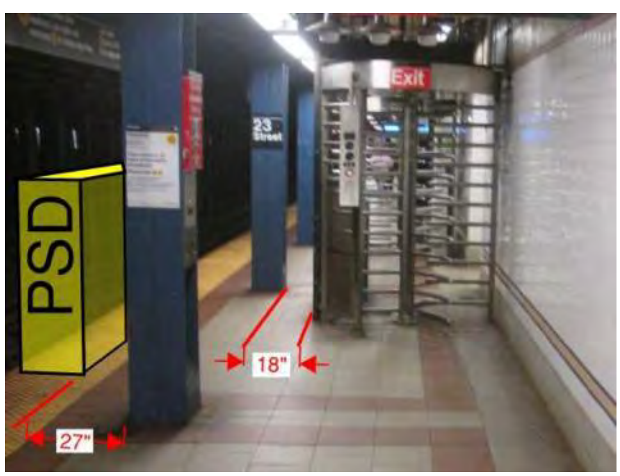

***Figure 2** – Non-Compliant ADA condition - 23rd Street*

1.15 – MR 015 | 14th Street / Union Square Station

Summary: *14th Street / Union Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the L-line and 4,5,6-line for the remainder of this complex)*

Description

14th Street / Union Square Station is a below-grade station consisting of two center / island platforms. The platform width is 18-8" throughout. The platforms are straight with two rows of columns at 3'-6" from edge of platform; these columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
14th Street / Union Square

Table of Contents

1.16 – MR 016 | 8th Street Station

Summary: *8th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

8th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-4" from the platform edge at each platform. The platform width varies from 9'-6" to 11'-0" in width. The south street stair at each platform is positioned with minimal clearance to the adjacent columns. The remaining space between the columns and the platform edge measures 40". The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
8th Street Station

1.17 – MR 017 | Prince Street Station

Summary: *Prince Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

Prince Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-6' to 8'-8". Platform width at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement.. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Prince Street

1.18 – MR 018 | Canal Street Station Upper Level

Summary: *Canal Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

Canal Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-0' to 11'-8". Platform width at the south end of the northbound platform is 48". The implementation of a platform edge barrier would reduce this width to 33" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Canal Street Station

1.19 – MR 019 | Canal Street Station Lower Level

***Summary:** Canal Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Canal Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The typical width of the platforms ranges from 7'-0' to 9'-6". Platform widths are not wide enough to accommodate an equipment room (Figure 2) and the mezzanine cannot accommodate a full-size equipment room without constraining passenger flow.

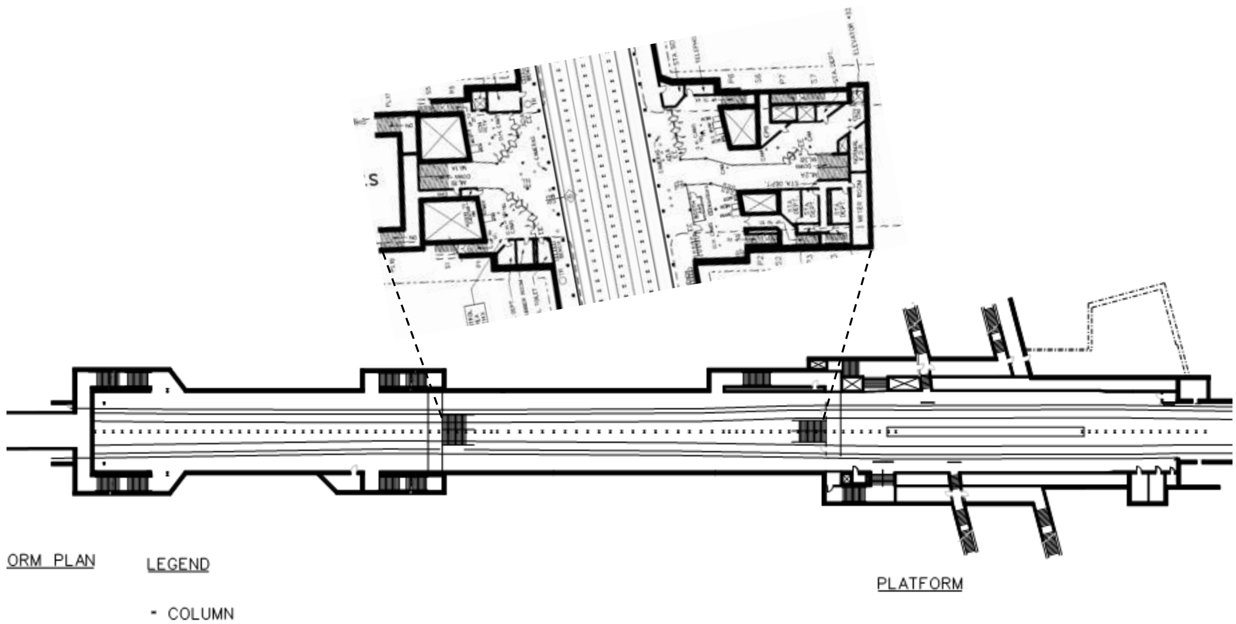

***Figure 1** – Station layout showing lack of space*
Canal Street Station Lower Level – Mezzanine shown above

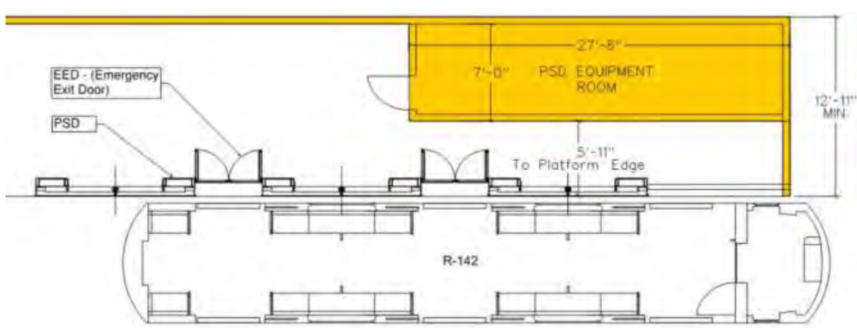

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.20 – MR 020 | City Hall Station

Summary: *City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

City Hall Station is a below-grade station with a center / island platform. The platform structure is cast-in-place concrete. The platform width varies from 23'-8" to 46'-4". There are four lines of columns, with those adjacent to the track being 3'-4" from the platform edge. Ceiling heights measure no less than 7'-6" throughout. At the stair to the lower level, clearance along the platform edge is constricted by columns subdividing the space into two narrow widths. The available 40" width between columns and platform edge will be further constricted by the introduction of PSDs, reducing the width to 25" or less* which would not allow for ADA compliant wheelchair movement. See Figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
City Hall Station

1.21 – MR 021 | Cortlandt Street Station

Summary: *Cortlandt Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-3"" (see figure 1).*

Description

Cortlandt Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-3' to 19'-8". There are two ceiling-mounted signals at each platform at a minimum 6'-11" clearance.

Platform width at the south end of the northbound platform is 5'-3". The installation of a platform edge barrier will reduce the width to 48" or less*. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant code condition*
Cortlandt Street Station

1.22 – MR 022 | Rector Street Station

Summary: *Rector Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound control area as the remaining width would be 25" (see figure 1).*

Description

Rector Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 10'-2' to 11'-8". At the turnstile line on the northbound platform, clearance between the turnstiles and the row of columns is only 20". At this area there is 40" between the columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32" for a pinch point. The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference. The plan of this area shown in Figure 2 reveals the constrained conditions within the unpaid area and demonstrates that there is no available space for reconfiguration of turnstiles to ameliorate the non-compliant conditions.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant code condition*
Rector Street Station

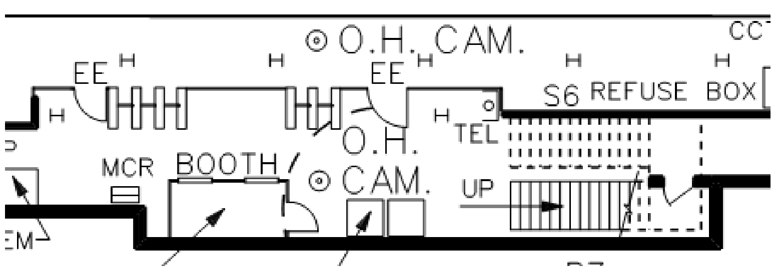

***Figure 2** – Constrained control area; northbound platform*
Rector Street Station

1.23 – MR 023 | Whitehall Street Station

Summary: *Whitehall Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

Whitehall Street Station is an underground station consisting two center / island platforms. The platforms are approximately 12'-6" wide throughout. At four staircases, columns flank the stair, leaving a dimension of 36" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Whitehall Street Station

1.24 – MR 024 | Court Street Station

Summary: *Court Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors. (see figure 1).*

Description

The Court Street Station is a below grade station with a center / island platform. The platform structure is cast-in-place concrete. The width of the platform varies from 15'-2" to 19'-2". Several columns are 16" from the platform edge. In that position, the columns block access to the maintenance panels of the PSDs. In addition, the columns impede the ability to open the hinged emergency egress doors which are mounted between every PSD sliding door. **(see Figure 1)**.

Figure 1 – *Obstruction at platform edge*
Court Street Station

1.25 – MR 025 | Jay Street / Metrotech Station

Summary: *Jay Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor width and the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 9" (see figure 1).*

Description

The Jay Street Station is a below grade station with a center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 14'-0" throughout. Columns are spaced 13'-0" on center. There is one staircase along the platform adjacent to these columns. The column faces are 24" away from all platform edges. The implementation of a platform edge barrier would reduce this width to 9"" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
Jay Street Station

1.26 – MR 026 | Dekalb Ave Station

Summary: *Dekalb Ave Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Dekalb Ave Station is a below-grade station with center / island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 10'-10" on center, and column faces typically measure 1'-6". The platform width is 15'-8" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment room for N line could be located at the south mezzanine. A second adjacent equipment room would serve the other two platforms which handle other train service. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last twenty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

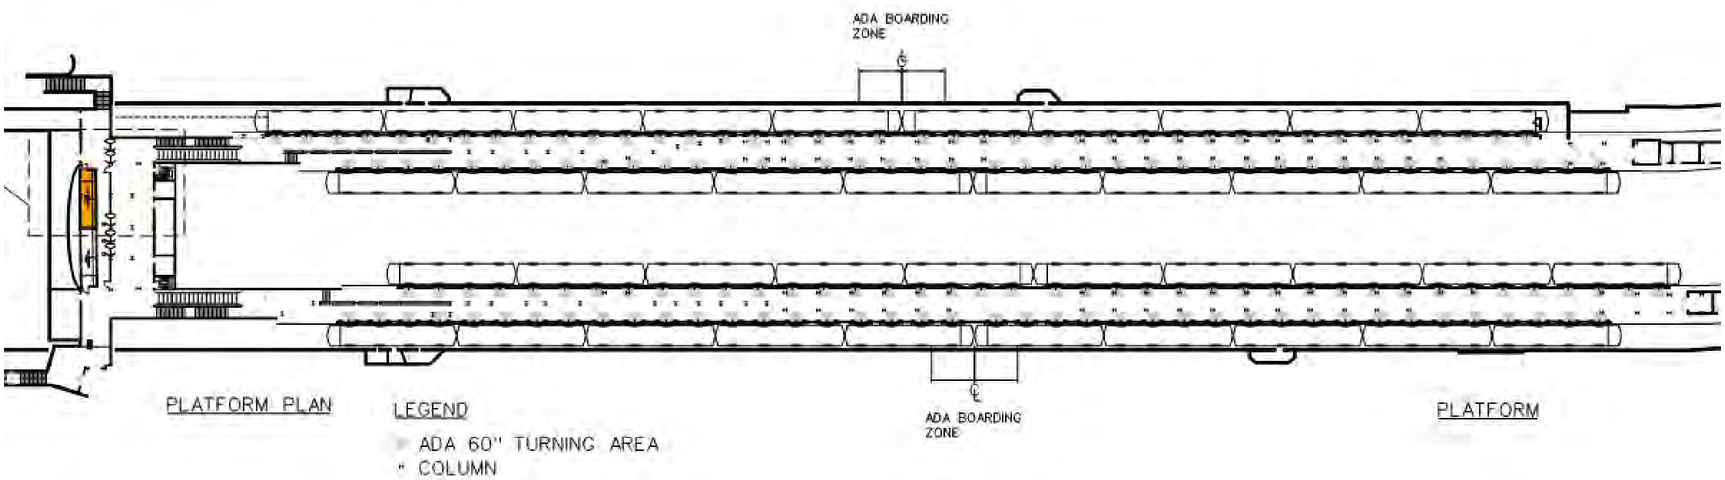

***Figure 1** – Overall Station Plan*
Dekalb Station

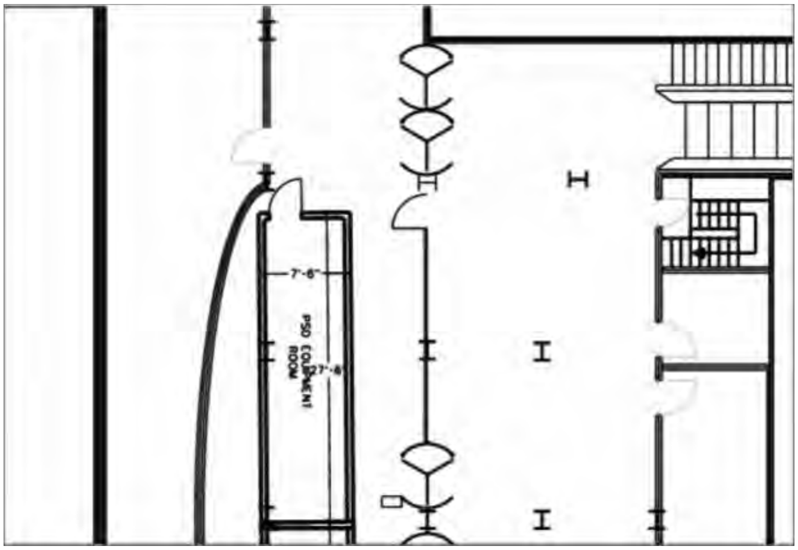

Figure 2 *– PSD Equipment Room 1 Detail*
Dekalb Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Dekalb Avenue Flatbush Ave
Peak Demand Load from ConEd Report, (kW)	95.2
Apparent Power (kVA)	119.0
Station Peak Demand Load, Max Current, (A)	330.6
Maximum Number of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	671
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	529
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1-line diagram, having 1200A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service. This analysis is for **Normal service**.

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $32.2M to install APGs and $41.4M to install PSDs (See Appendix E).

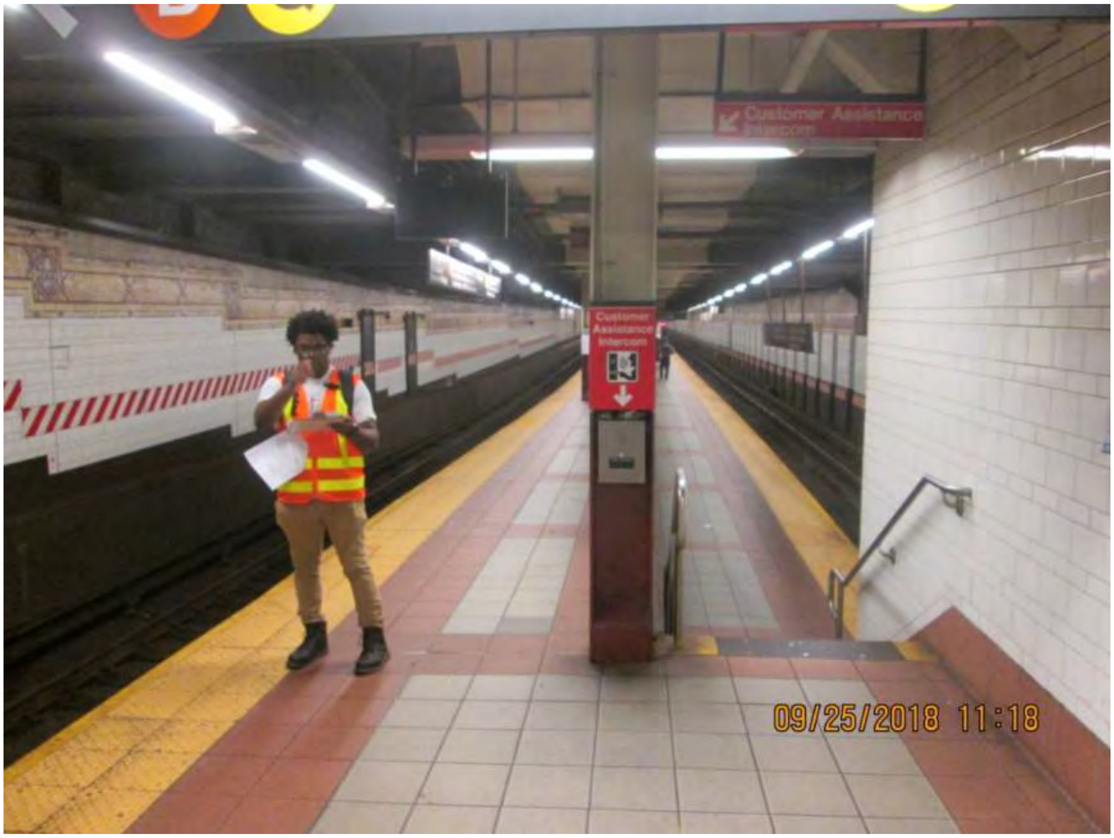

***Figure 3** – Typical platform view*
Dekalb Station

1.27 – MR 027 | Atlantic Ave Station

Summary: *Atlantic Ave Station is feasible for both APGs and PSDs. At the southbound platform, two columns adjacent to the platform edge would require removal and replacement at a more distant location. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Atlantic Ave Station is a below grade with two side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 15'-1/2" on center, and column faces are at varying distances from the platform edge. The platform width is 18'-8" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the south mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last twenty-five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

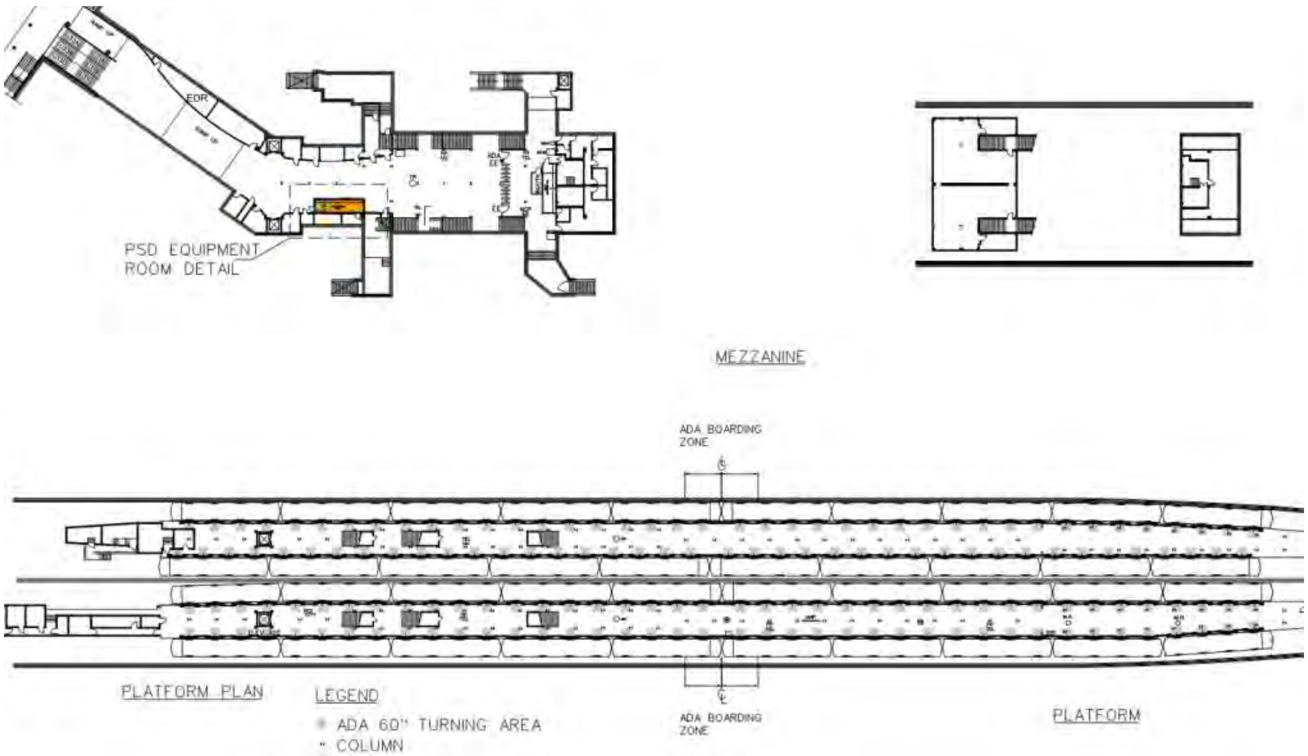

Figure 1 *– Overall Station Plan*
Atlantic Ave Station

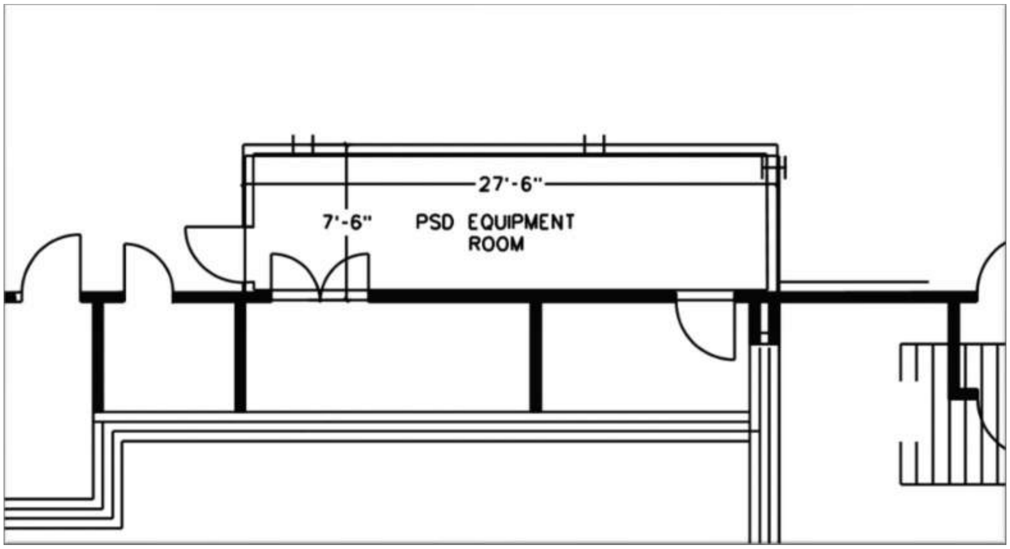

***Figure 2** – PSD Equipment Room 1 Detail*
Atlantic Ave Station

Platform obstructions within 5' of edge:

Southbound Track:

- One column is at 1'-0" from each platform edge. They will require removal and replacement as part of any PSD installation.

Northbound Track:

- None

These obstructions do not present an impediment to the installation of PSDs beyond the instances mentioned above.

Historic Restrictions:

The Atlantic Avenue station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.3M to install APGs and $39.9M to install PSDs (See Appendix E).

***Figure 3** – View of column at platform edge requiring removal and replacement*
Atlantic Ave Station

Table of Contents

1.28 – MR 028 | Union Street Station

Summary: *Union Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Union Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 2'-6" from the platform edge at each platform, at the northern third of the stations. The remainder of the platform is column-free. The platform width is 8'-8" throughout. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2 below shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

.

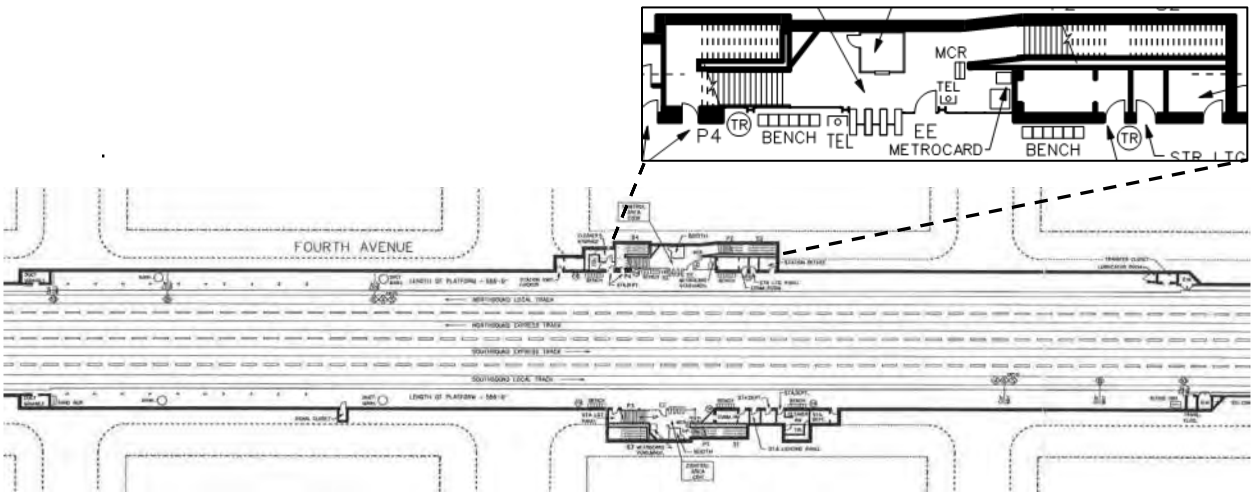

***Figure 1 –** Congested/Narrow Station Plan*
Union Street Station

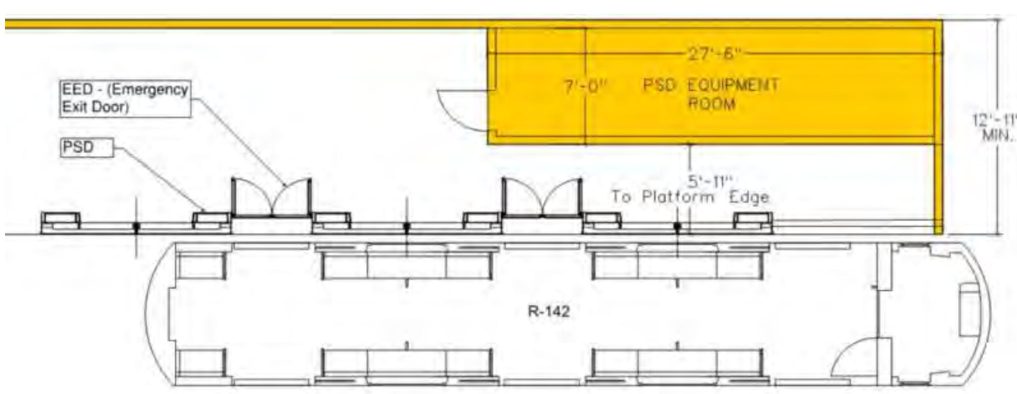

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.29 – MR 029 | 4th Ave / 9th St Station

Summary: *4th Ave / 9th St Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

4th Ave 9th St Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 8'-4" to 8'-8"." Columns are spaced 11'-10" on center with column faces 3'-0" away from the edge. The columns are present only on the northern third of both the platforms; the remainder of the platforms are column-free. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

4th Ave / 9th Street Station

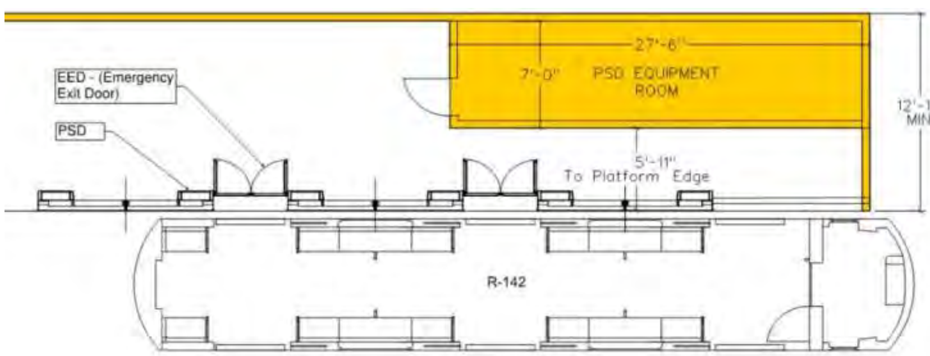

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.30 – MR 030 | Prospect Avenue Station

Summary: *Prospect Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

The Prospect Ave Station is a below-grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms and control areas, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

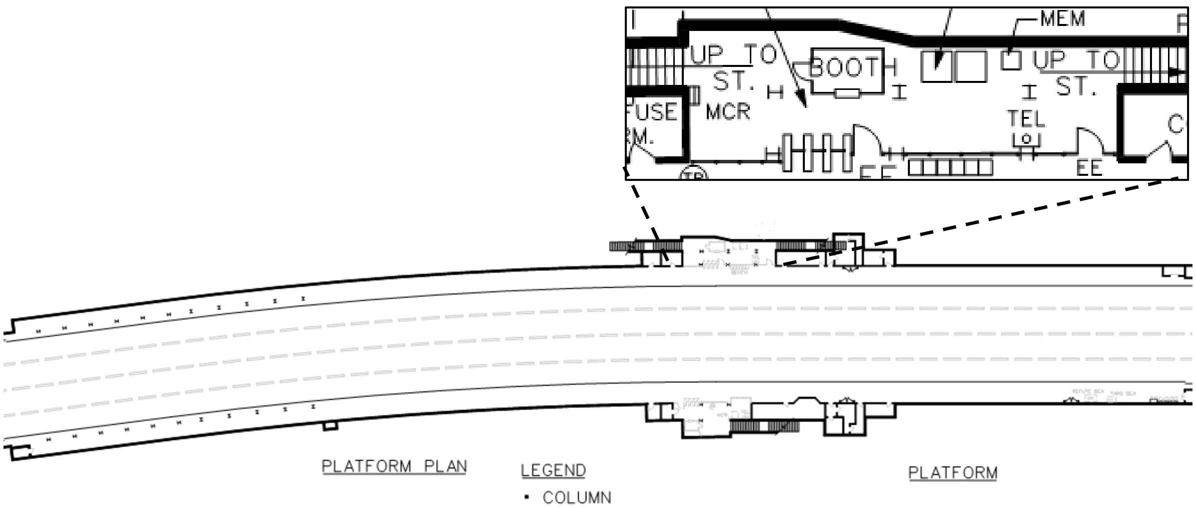

Figure 1 – *Congested/Narrow Station Plan*
Prospect Avenue Station

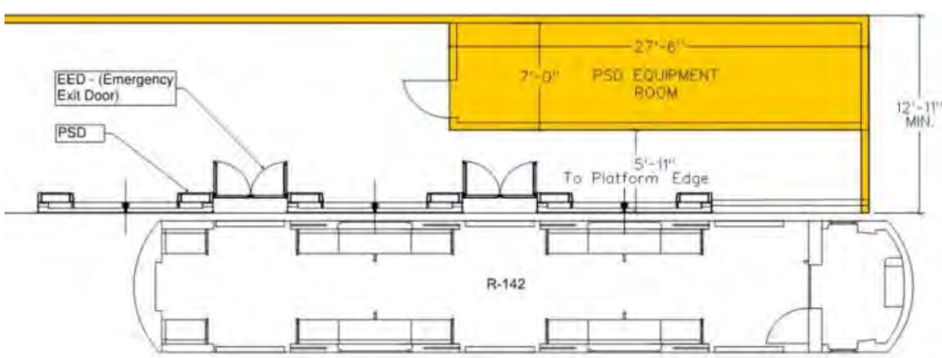

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.31 – MR 031 | 25th Street Station

Summary: *25th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

25th Street Station is a below grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

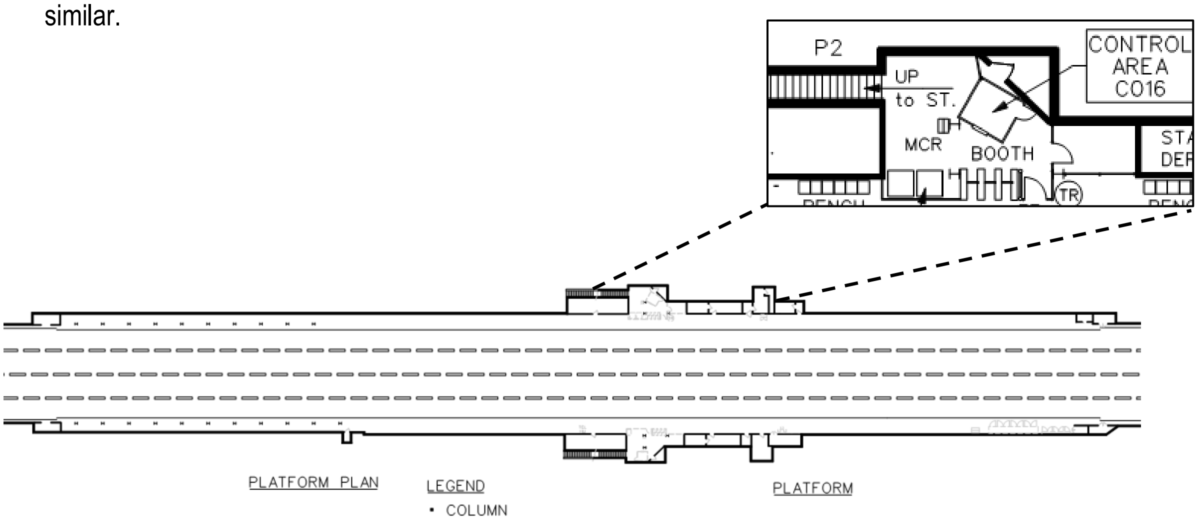

***Figure 1 –** Congested/Narrow Station Plan*
25th Street Station

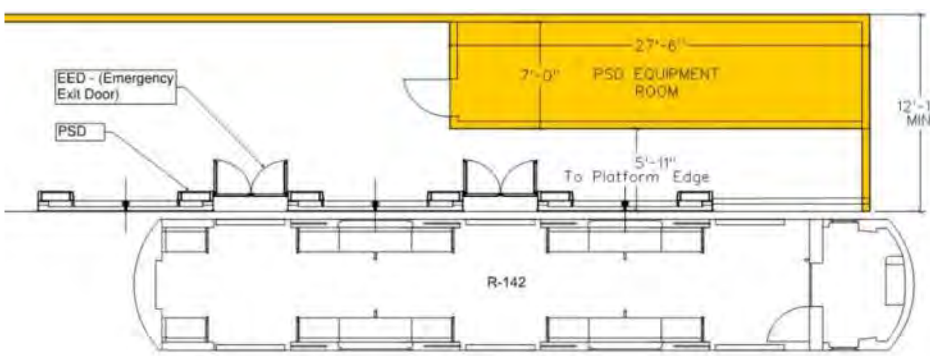

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.32 – MR 032 |36th Street Station

Summary: *36th Street Station is not feasible for both APGs and PSDs due to the row of columns at 12" from the platform edge. The barrier itself is15" thick and requires free space for maintenance purposes. (see figure 1).*

Description

The 36th Street Station is a below grade station with two center / island platforms. The platform structure is cast-in-place concrete. The width of the platforms varies from 13'-0" to 19'-2". Columns are spaced 15'-6" on center with column faces 1'-0" away from all platform edges. The inside face of the barrier itself is 15" minimum from the concrete platform edge, and requires free space for maintenance and operation. **(see Figure 1)**.

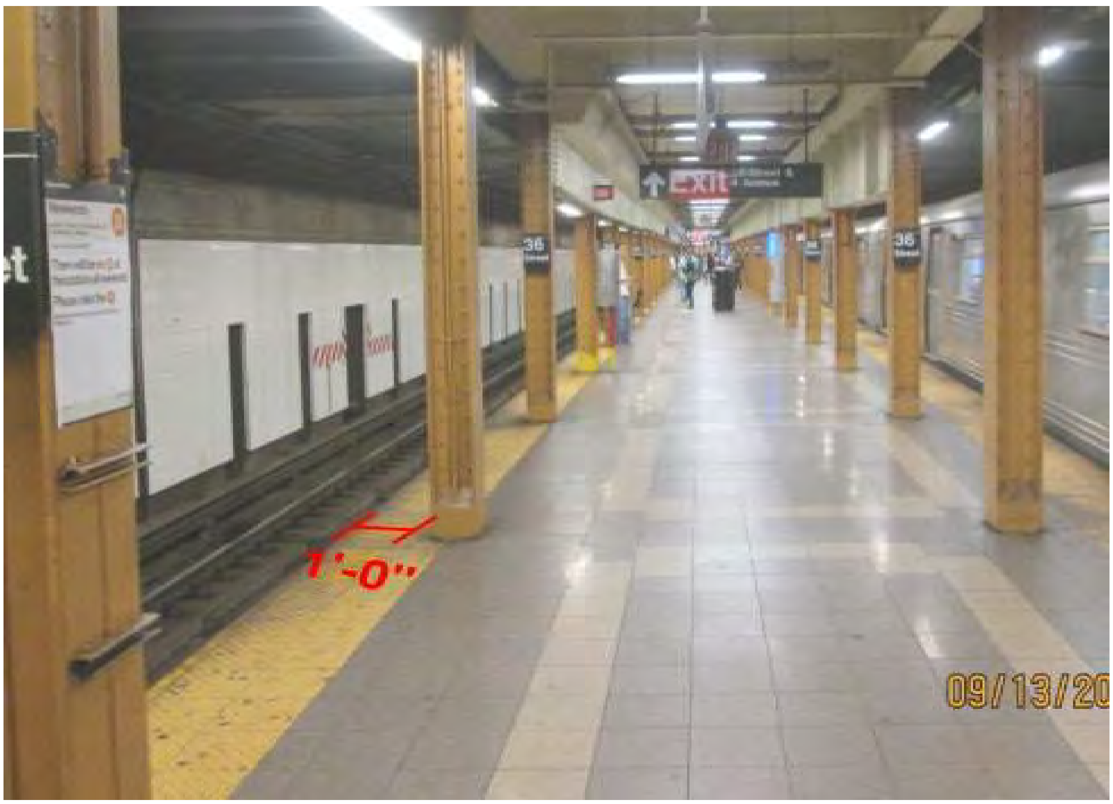

Figure 1 – *Obstruction within 12"*
36th Street

1.33 – MR 033 | 45th Street Station

Summary: *45th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs/walls as the remaining width would be 25" (see figure 1).*

Description

The 45th Street Station is a below grade station with two side straight platforms. The platform structure is cast-in-place concrete. The width of the platform varies 10'-8" to 15'-6". There is one room along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-6" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
45th Street Station

1.34 – MR 034 | 53rd Street Station

Summary: *53rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs/wall as the remaining width would be 23" (see figure 1).*

Description

The 53rd Street Station is a below grade station with two side straight platforms. The platform structure is cast-in-place concrete. The width of the platform varies 9'-6" to 10'-10". There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-2" on center with column faces 3'-2" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 23"or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1 –** Non-Compliant ADA condition*
53rd Street Station

Table of Contents

1.35 – MR 035 | 59th Street Station

Summary: *59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 33" (see figure 1).*

Description

The 59th Street Station is a below grade station with two center / island platforms. The platform structure is cast-in-place concrete. The width of the platform is varying 12'-8" to 17'-10". There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-1" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

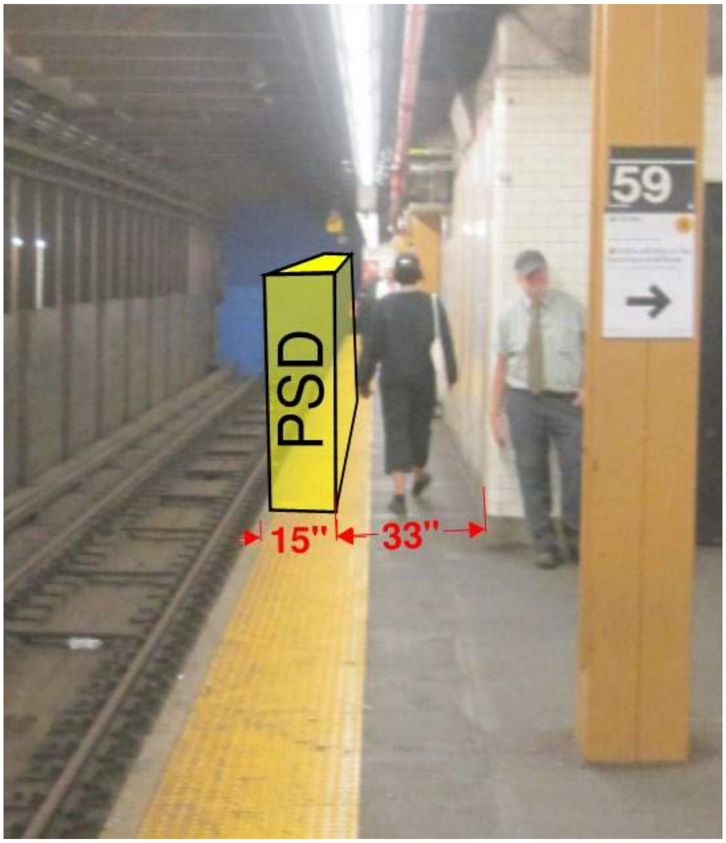

***Figure 1 –** Non-Compliant ADA condition*
59th Street Station

1.36 – MR 058 Coney Island-Stillwell Avenue Station

Summary: *Coney Island-Stillwell Avenue Station is feasible for both APGs and PSDs. This station is the terminus station for the 'N', 'Q', 'D', and 'F' trains. Tracks 1 and 2 serve the N line from a shared center / island platform. The canopy at this station is very tall, and there are no structural members directly above the platform edge. For the installation of a full height PSD system, structural members would have to be attached to existing beams that are approximately 12'-0" high and 5'-0" from the platform edge. One and a half train cars are not covered by a canopy. Therefore, a supplemental overhead structure would be needed in this part of the platform. Platform edge reconstruction will be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Coney Island-Stillwell Avenue Station is an elevated station with four center/island platforms. Each train that is served at this station has a center/island platform for its use only. The 'N' line platform is mostly straight, but tapers at the north-end of the platform. The platform structure is made of cast-in-place concrete. There are two stairs and a centrally located ramp that provide access to the mezzanine level below. There are two rows of columns along the length of the platform. These columns are spaced approximately 20'-0" on center with column faces 6'-10" from the platform edge. The platform varies from 20'-0" to 26'-0" wide. One and a half train cars are not covered by the canopy. A supplementary overhead structure would be required in these locations to accommodate a platform edge barrier. See figure 1 for an overall station plan.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As indicated in the summary, there is not structure to mount to directly above the platform edge, some additional framing would be needed in this station (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be in coordination with existing or replacement lighting. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated on the platform between columns at the center of the platform. The proposed room would measure approximately 16'-0" x 7'-6" (see figure 2). The other lines that are served at this station could use a similar room location on their respective platform (see figure 1)

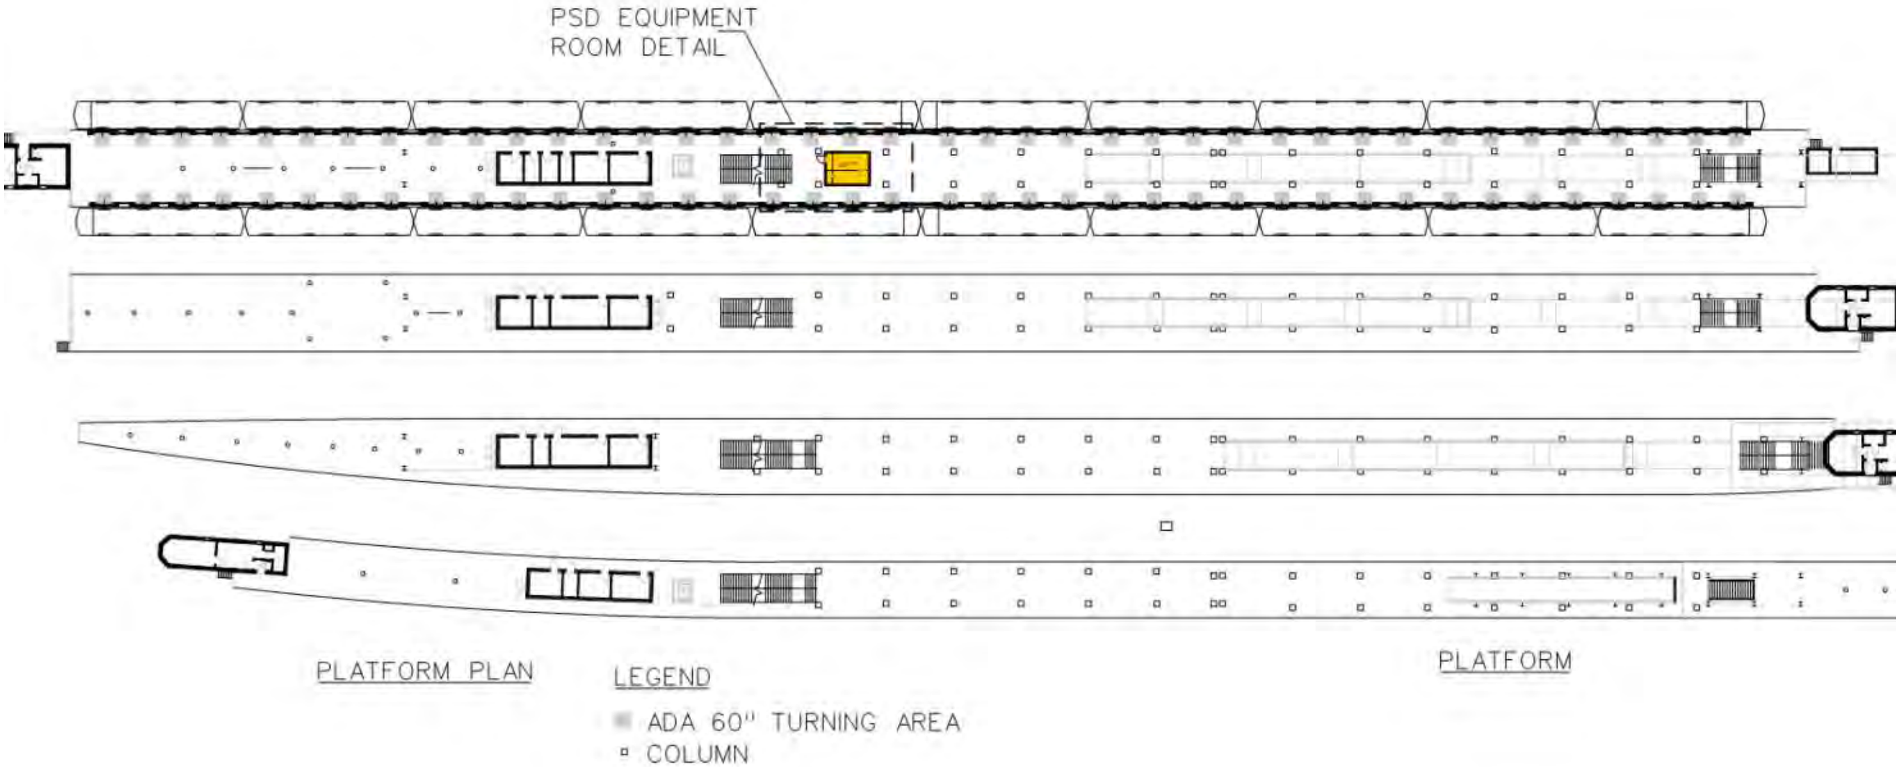

***Figure 1** – Station Plan*
Coney Island-Stillwell Avenue Station

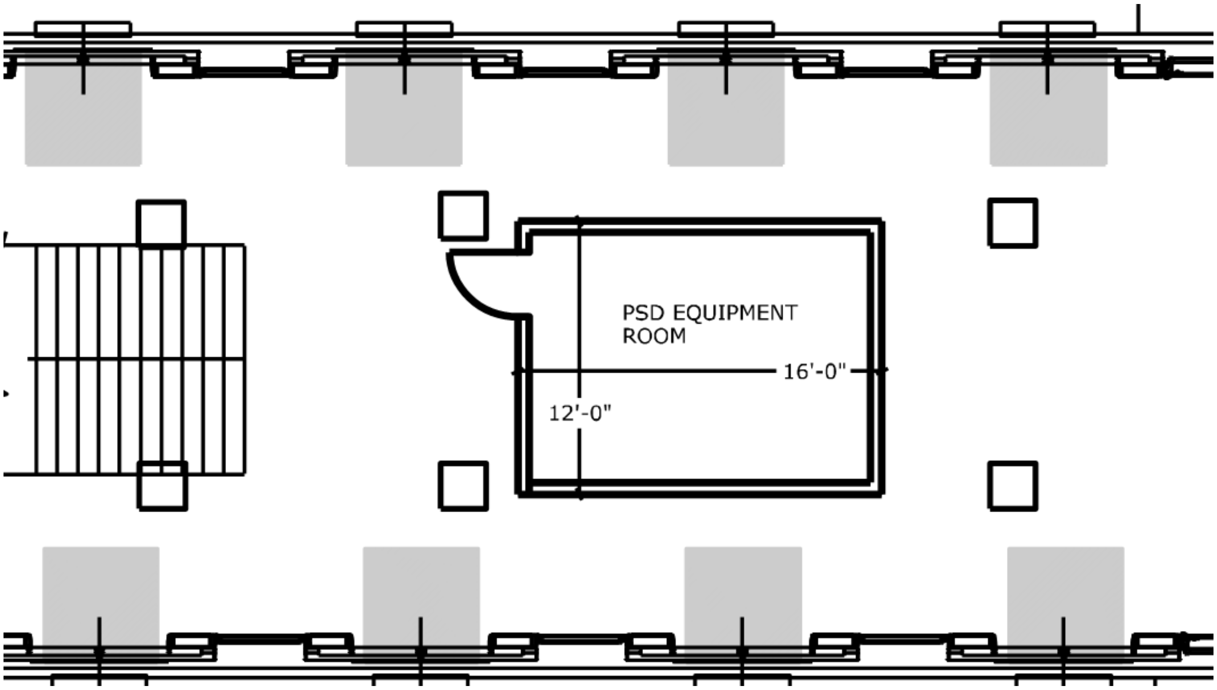

***Figure 2** – PSD Equipment Room Detail*
Coney Island-Stillwell Avenue Station

Track Layout

Tracks are mostly tangent with the exception of the tapered north-end of the platform. Thus, we are expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

The platform edges were reconstructed in 2004. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required only for the installation of an APG system.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: Linear fluorescent lights are mounted below the beams that run parallel to the platform. These beams are approximately 12'-0" high and 5'-0" from the edge of the platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

The existing Reserve electrical service is adequate for the installation of PSD/APG's. However, the Normal service is not adequate and therefore would not serve as a back-up system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 and Table 2 please see the Power Capacity Analysis for this station.

Station (Normal)
Power Capacity Analysis

Station Name	Coney Island Stillwell / Surf Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	552.0
Apparent Power (kVA)	690.0
Station Peak Demand Load, Max Current, (A)	1916.7
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	2549
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	This is for Normal service only. Station has (2) separate meter readings (not combined). Normal service has exceeded its service rating. **NO** additional load be connected to this normal service.

Table 1. Power Capacity Analysis (Normal Service)

Station (Reserve)
Power Capacity Analysis

Station Name	Coney Island Stillwell / Surf Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	112.0
Apparent Power (kVA)	140.0
Station Peak Demand Load, Max Current, (A)	388.9
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	1022
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	179
Is Electrical Service Adequate?	Yes
Notes	This is for Reserve service only. This is based on assumption that each Service is separate. Reserve service has spare capacity. (Normal service has **NO** spare capacity)

Table 2. Power Capacity Analysis (Reserve Service)

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.0M to install APGs and $39.9M to install PSDs (See Appendix E).

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'N' Line Stations
(Coney Island-Stillwell Avenue Station)

Figure 3 *– Typical platform edge condition with line of potential supplementary framing*
Coney Island-Stillwell Avenue Station

1.37 – MR 071 | 8th Ave Station

Summary: *8th Ave is feasible for both APGs and PSDs. At both platforms, one column adjacent to the platform edge would require removal and replacement at a more distant location. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

8th Ave Station is an open cut station with two side curved platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 12'-0" on center, and column faces typically measure 6". The platform width varies from 11'-0" to 12'-8" throughout. One column on each platform supports the main mezzanine above. These columns stand 1'-0" from the platform edge and would therefore need to be removed and replaced as part of a PSD installation.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are 2 platform edges at this station, 1 full size equipment rooms would be required. For the planning purposes, the location of the equipment room has been examined to assure feasibility for the station as a whole. The equipment room could be located at the far north end of the mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are on a mild radius. Therefore, the gaps between the platform and train will slightly exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

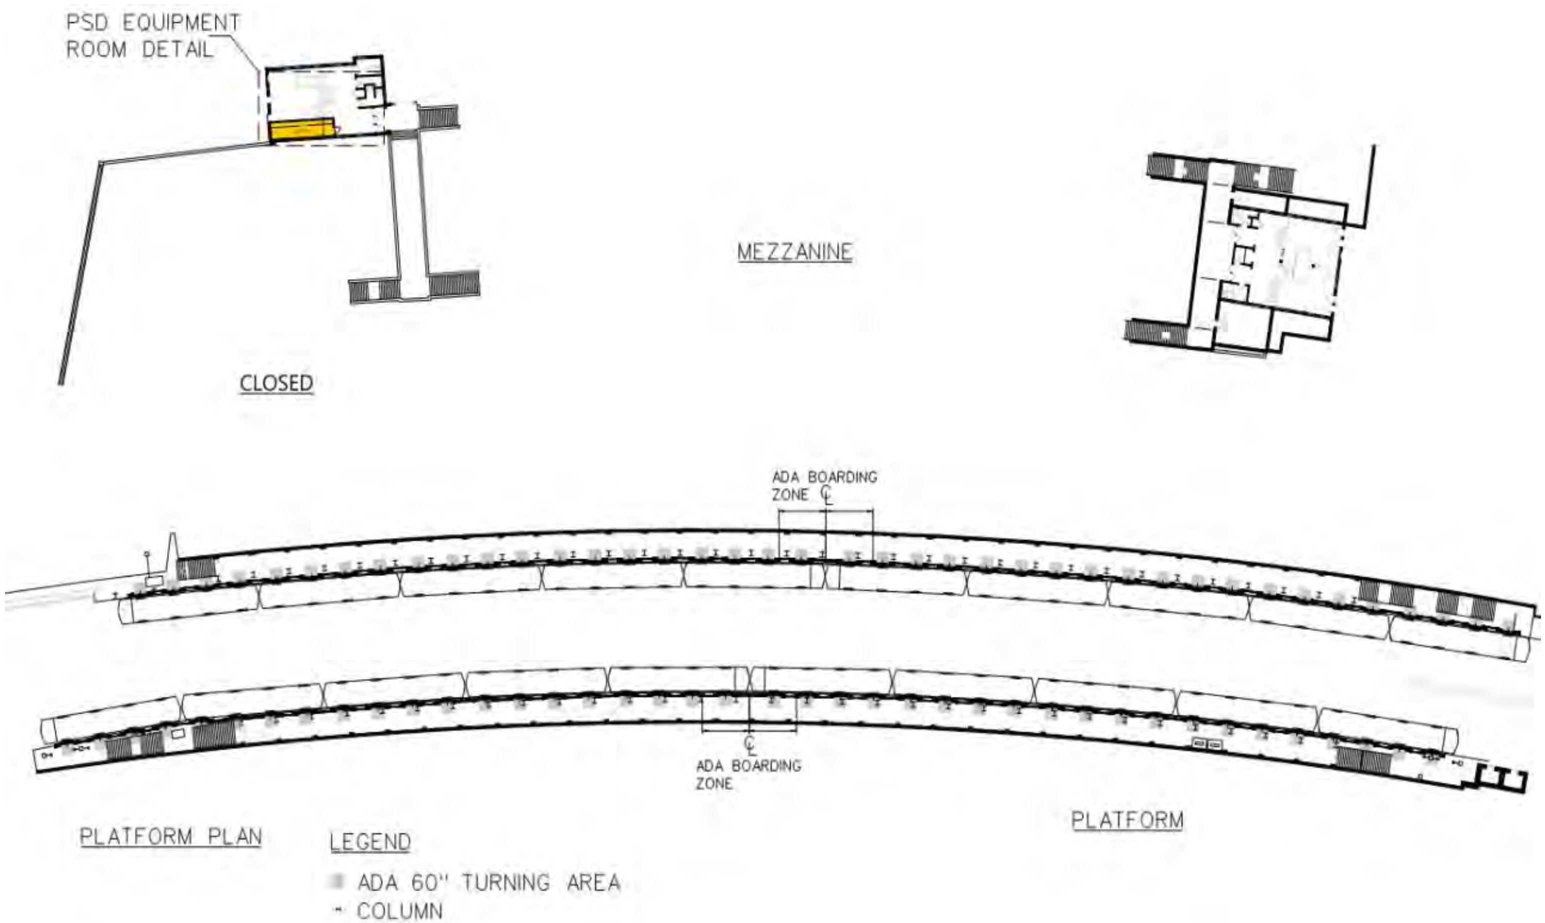

***Figure 1** – Overall Station Plan*
8th Ave Station

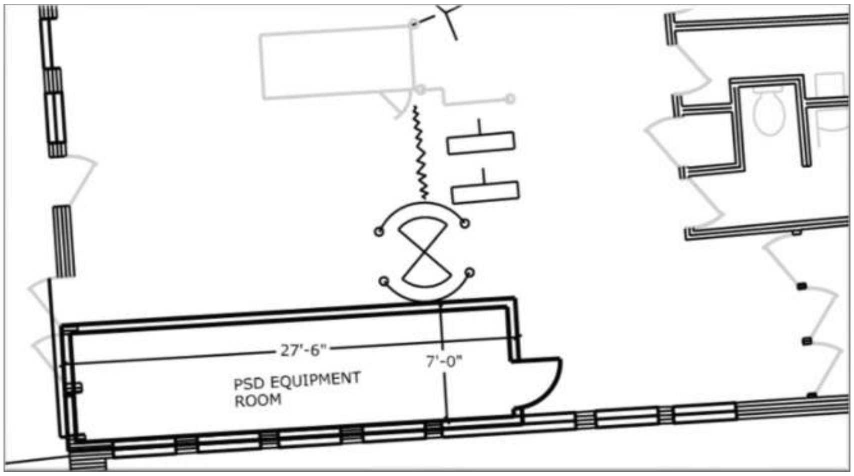

***Figure 2** – PSD Equipment Room 1 Detail*

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

At each platform, one column supporting the mezzanine sits adjacent to the proposed PSD location, making installation infeasible. An installation of PSDs at this station will require structural work to replace the columns at a different location. The remainder of columns do not present an impediment to the installation of PSDs.

Lighting:

Existing lighting: Throughout both platforms there is linear florescent parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station

8th Ave Station

Figure 4 *– Platform column (1 of 2) which will require removal and replacement*
8th Ave Station

1.38 – MR 072 | Fort Hamilton Pkwy Station

Summary: *Fort Hamilton Pkwy Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained at this station due to ongoing construction. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Fort Hamilton Pkwy Station is an open cut station with two side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Information on existing drawings indicate that the platform columns on the southbound platform are spaced 12'-0" on center, and column faces are typically 2'-8" from the platform edge. The northbound platform is column-free. The standard platform width is 8'-10" throughout. (Survey was limited to the northbound platform due to ongoing construction)

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 2 platform edges at this station, 1 full size equipment rooms would be required. The equipment room could be located at the south mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

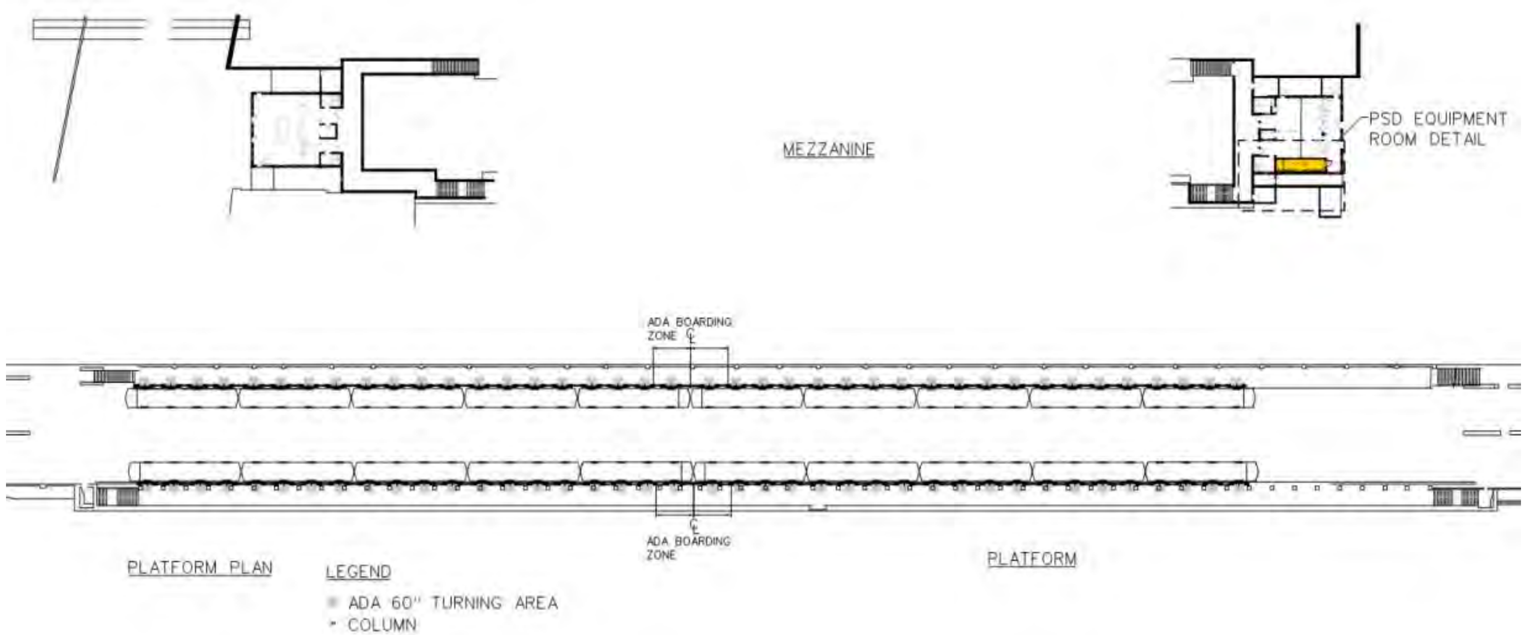

***Figure 1** – Overall Station Plan*
Fort Hamilton Station

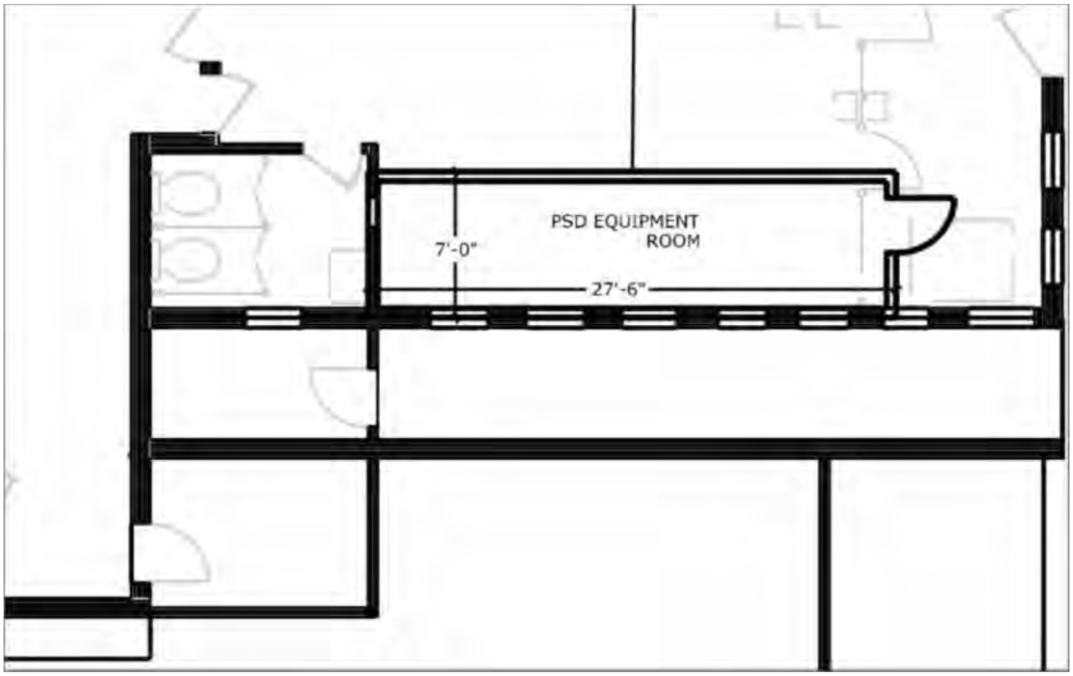

Figure 2 *– PSD Equipment Room 1 Detail*
Fort Hamilton Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- None

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there is linear florescent parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

***Figure 3** – Typical platform view Fort Hamilton Station*

Historic Restrictions:

None.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.7M to install APGs and $39.8M to install PSDs (See Appendix E).

Table of Contents

1.39 – MR 073 | New Utrecht Ave

***Summary:** New Utrecht Ave station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

The New Utrecht Ave station is an open cut station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 12'-2" throughout. There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 9'-8" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1 –** Non-Compliant ADA condition*
New Utrecht Avenue

1.40 – MR 074 | 18th Ave Station

Summary: *18th Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 31" (see figure 1).*

Description

The 18th Ave Station is an open cut station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 12'-0" throughout. There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 12'-0" on center with column faces 3'-10" away from all platform edges. The implementation of a platform edge barrier would reduce this width to 31" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
18th Avenue Station

Table of Contents

1.41– MR 075 | 20th Ave Station

Summary: *20th Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

20th Ave Station is an open cut station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-0" from the platform edge at each platform. The platform width is approximately 12'-0" throughout. There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 12'-2" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Plan of proposed PSD equipment room*
20th Ave Station

1.42 – MR 076 | Bay Parkway Station

Summary: *Bay Parkway is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bay Parkway Station is open cut construction with two side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 12'-0" on center, and column faces typically measure 1'-4". The standard platform width is 12'-0" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 2 platform edges at this station, 1 full size equipment room would be required. The equipment room could be located at the far south end of the mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

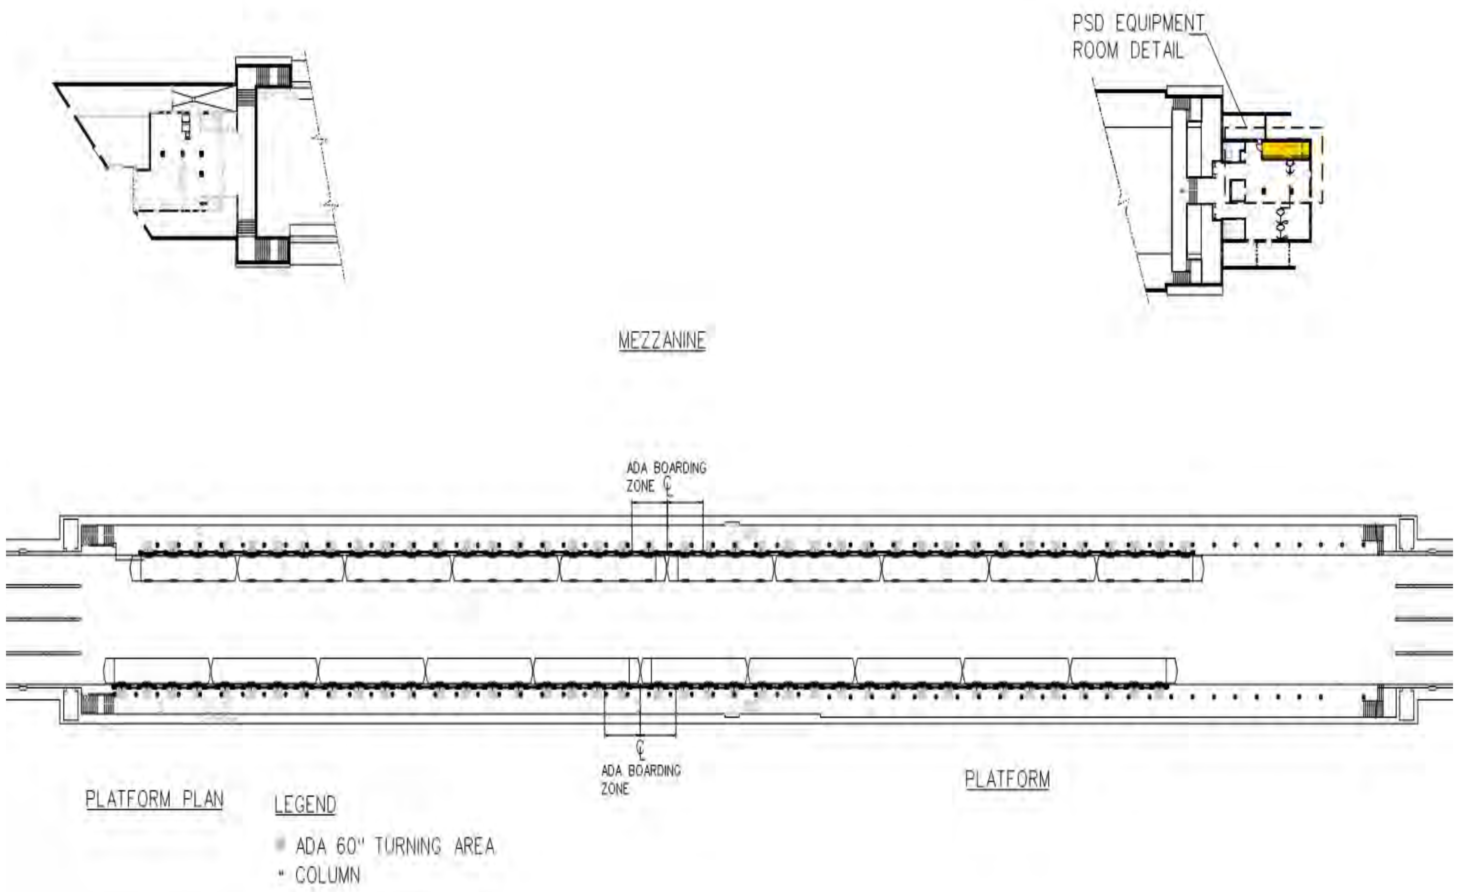

***Figure 1** – Overall Station Plan*
Bay Parkway Station

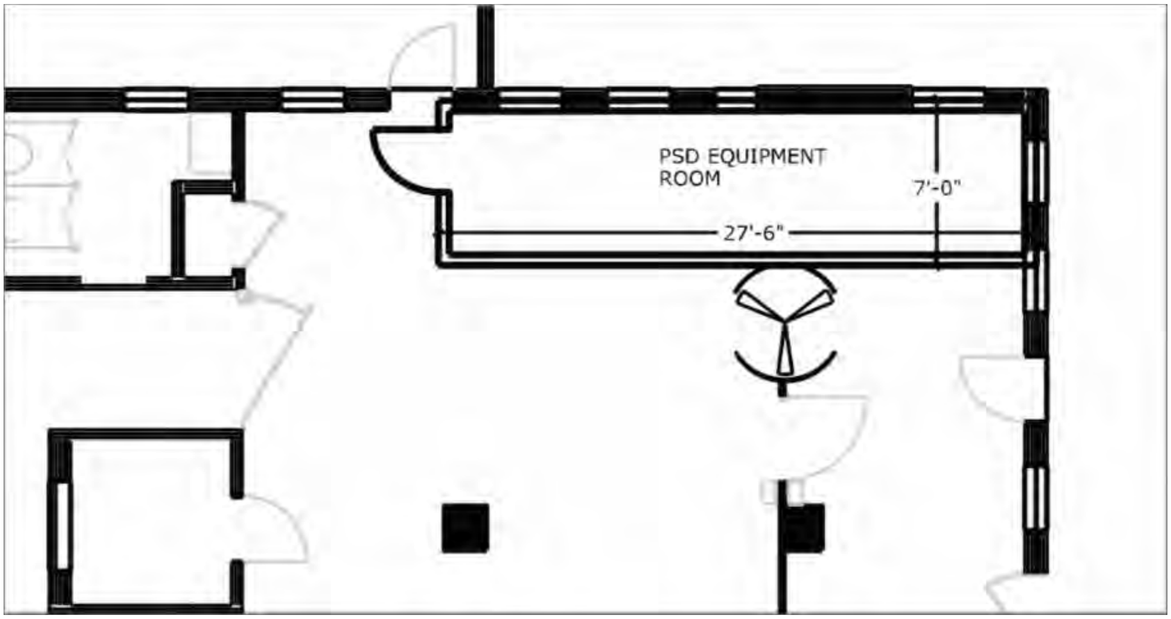

***Figure 2** – PSD Equipment Room 1 Detail*
Bay Parkway Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.6M to install APGs and $41.3M to install PSDs (See Appendix E).

Figure 3 *– Typical platform view*
Bay Parkway Station

1.43– MR 077 | Kings Hwy Station

Summary: *Kings Hwy Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Kings Hwy Station is an open cut station with two side platforms. The platform structures are cast-in-place concrete. The width of the southbound platform is approximately 12'-0" throughout. Columns are spaced 11'-10" on center with column faces 3'-0" away from the platform edge. Due to the extremely limited width of the existing platforms, an equipment room would not fit on either platform (see Figure 2). The mezzanines are likewise extremely limited in size, and therefore cannot serve as a location for the equipment room. See figure 1 below. (Note: the southbound platform was not surveyed due to ongoing construction)

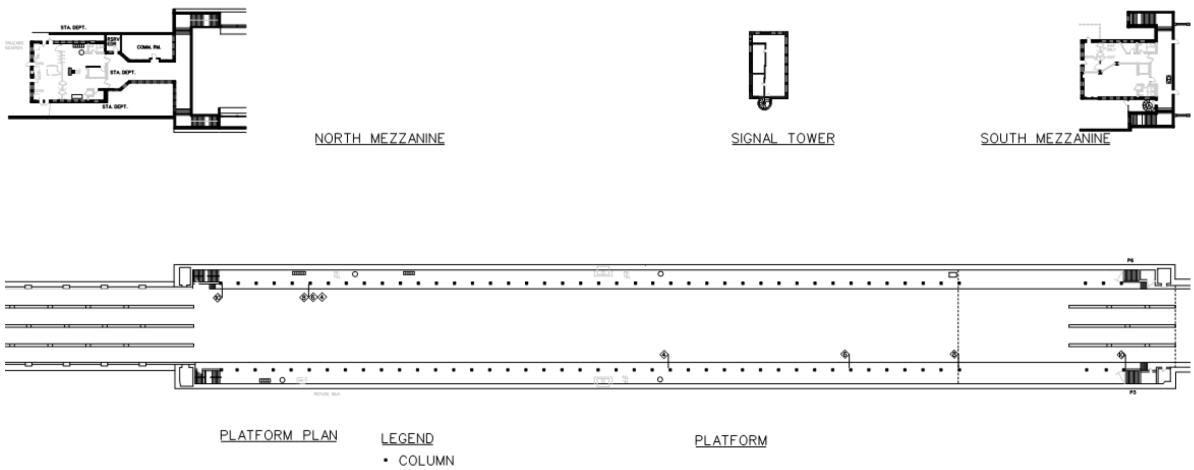

Figure 1 – *Congested/Narrow Station Plan*
Kings Hwy Station

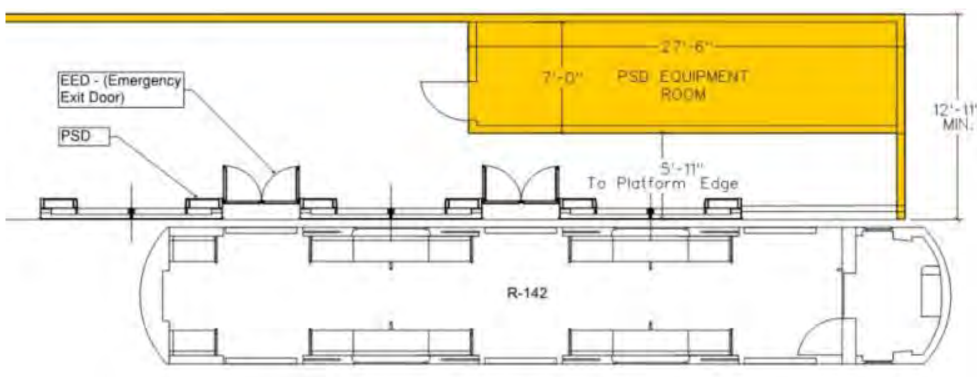

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.44 – MR 078 | Avenue U Station

Summary: *Avenue U Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Avenue U Station is open cut with two side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 12'-0" on center, and column faces typically measure 3'-0" from the platform edge. The standard platform width is 12'-0" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Since there are 2 platform edges at this station, 1 full size equipment rooms would be required. The equipment room could be located at the north mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

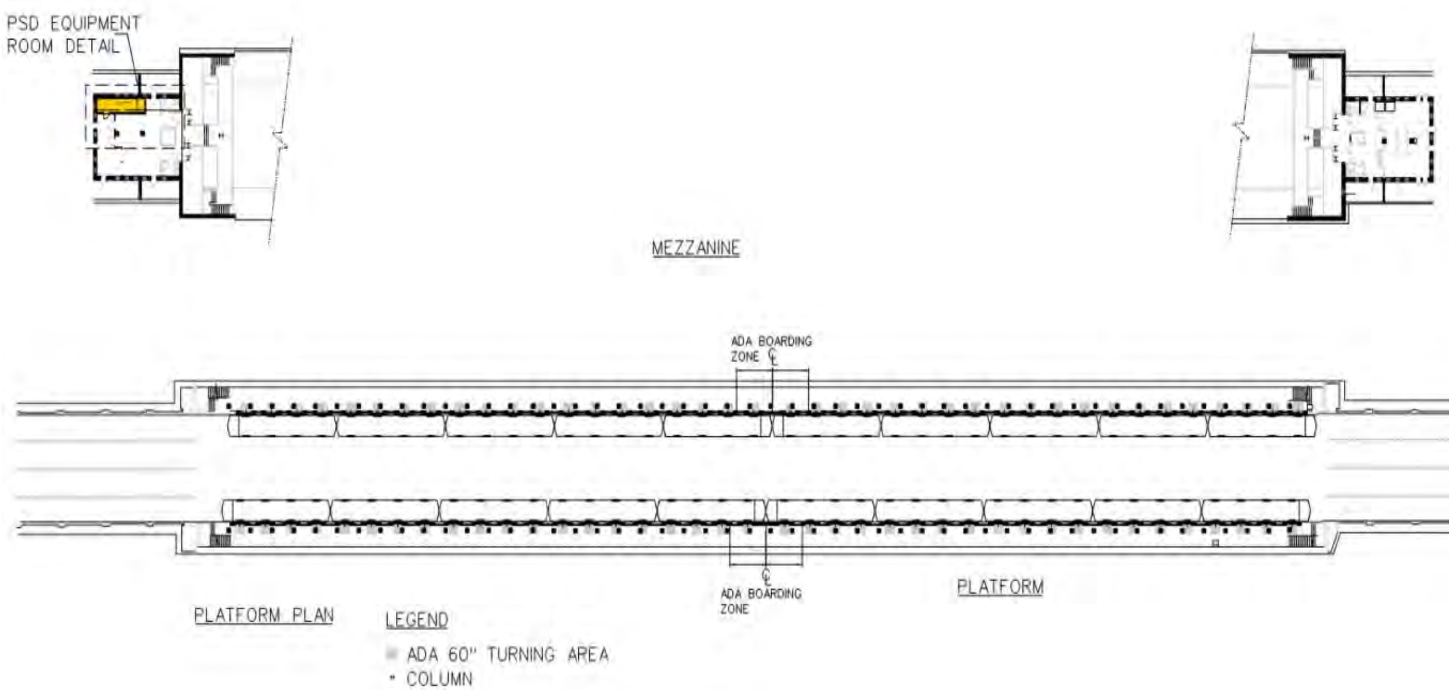

Figure 1 *– Overall Station Plan*
Avenue U Station

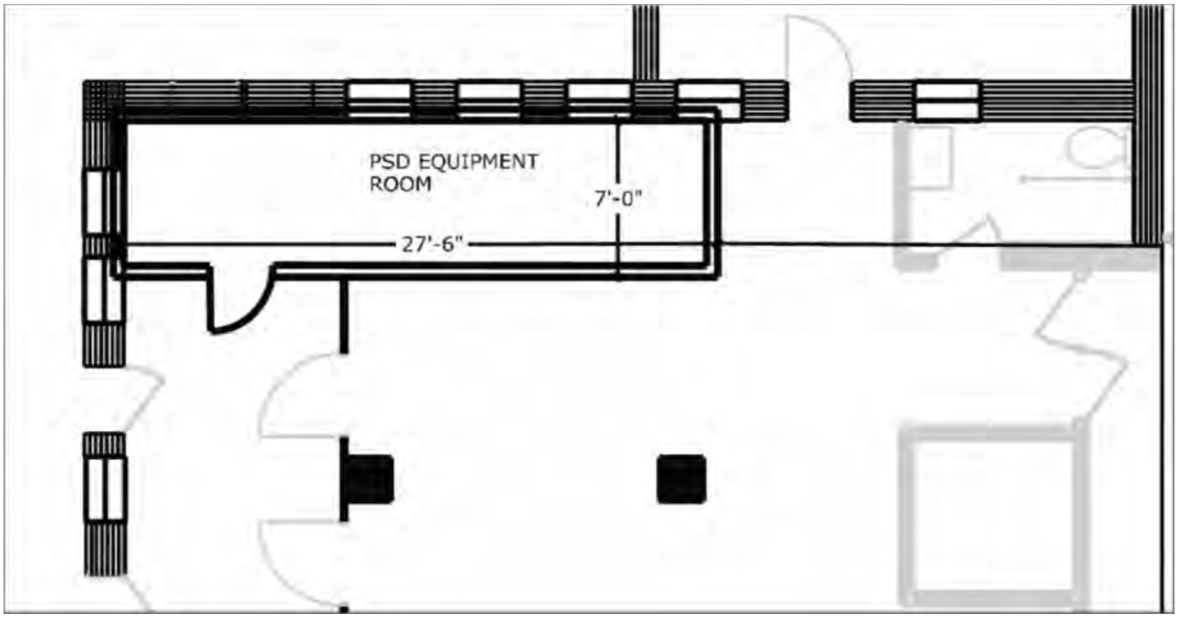

Figure 2 *– PSD Equipment Room 1 Detail*
Avenue U Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station

Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	196.7
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	603
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service. This analysis is for **Reserve service**. The meter # for reserve service should be # 9360801

Table 2*- Power Capacity Analysis (Reserve Service)*

Historic Restrictions:
The Avenue U station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.9M to install APGs and $38.4M to install PSDs (See Appendix E).

Table of Contents

Figure 3 *– Typical platform view*
Avenue U Station

1.45 – MR 079 | 86th Street Station

Summary: *86th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

The 86th Street Station is an open cut station with two side platforms. The platform structures are cast-in-place concrete. The width of the platform is approximately 12'-2" throughout. There is one staircase along the northbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 7'-3" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
86th Street Station

1.46 – MR 461 | Queensboro Plaza Station

Summary: *Queensboro Plaza Station is feasible for APGs only. The "7", "N" and "W" trains are served on both the upper & lower levels, with the 7 train and N/W trains on opposite sides of the center / island platforms. The No. 7 sides of these platforms are the subject of a separate station report. Full height PSDs are infeasible due to low beams above the platform edge at the upper level platform. Platform edge reconstruction will be required to support an APG system (see Appendix B). Existing power is adequate.*

Description

Queensboro Plaza Station is elevated with two straight center / island platforms stacked on top of each other. See figure 1 for an overall station plan. Both platforms are made of cast-in-place concrete. On the southbound platform, columns are spaced 48' on center with column faces 4'-8" from the platform edge. On the lower platform, columns are spaced 24' on center with column faces 2'-2" from the platform edge. Both platforms are approximately 19'-6" wide. On the lower platform, there is a vertical clearance of approximately 8'-0", which reduces to 7'-2" at the east-end of the platform. On the upper platform, there is a vertical clearance of approximately 7'-2" to canopy beams at the platform edge.

Full Height PSDs: Full height PSDs are infeasible due to the low beams of the canopy at the upper level platform. The bottom of the existing beams are at 7'-10", whereas PSD manufacturers require 8'-6" of height.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall mounted conduits below the upper and lower platform edge would need to be relocated to accommodate the requirements of the APG system. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated at the eastern end of the upper platform. The proposed room would measure approximately 27' x 7'-6" (see figure 2). As there are four platform edges at this station (including the No. 7 train – covered in a separate report), two equipment rooms would be needed to accommodate all of the required equipment. An additional room can be located in a similar location on the lower platform.

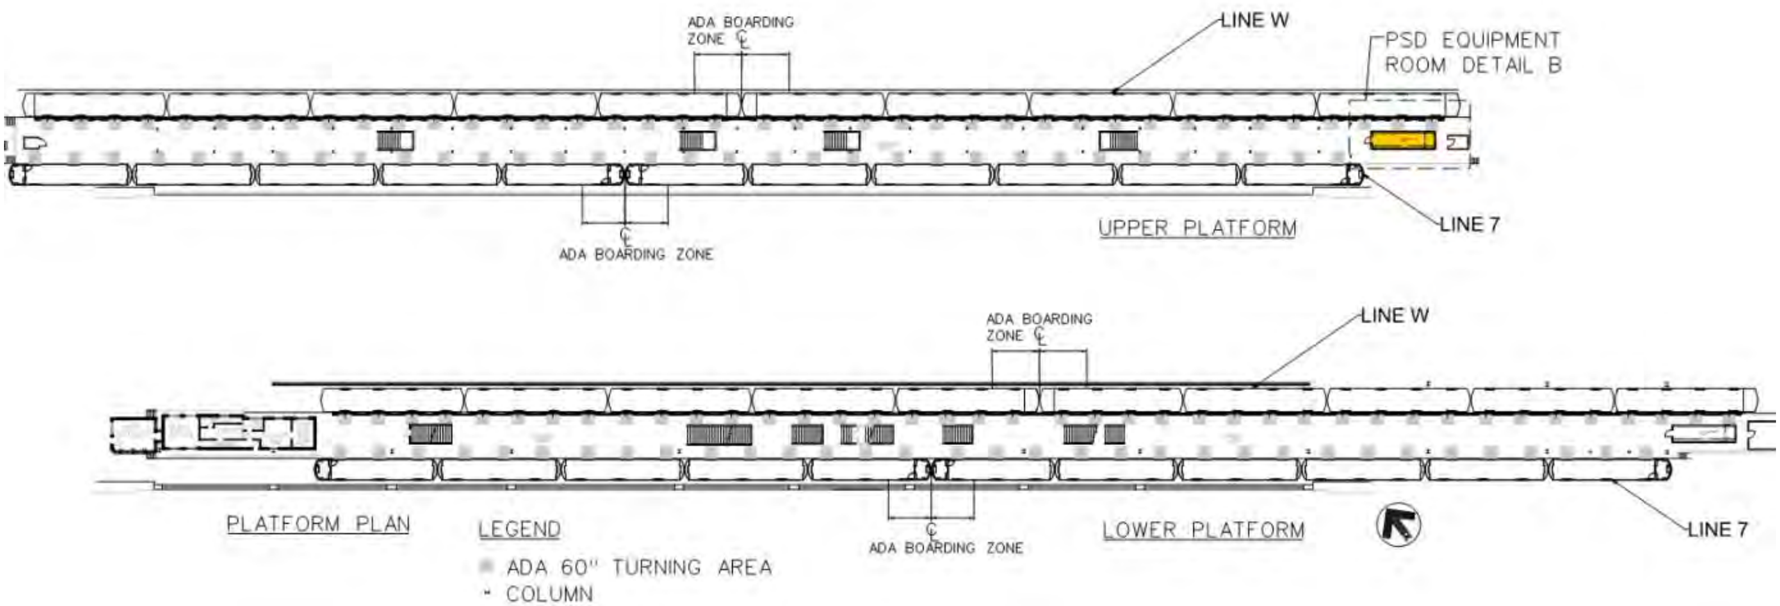

***Figure 1** – Platform plans*
Queensboro Plaza Station

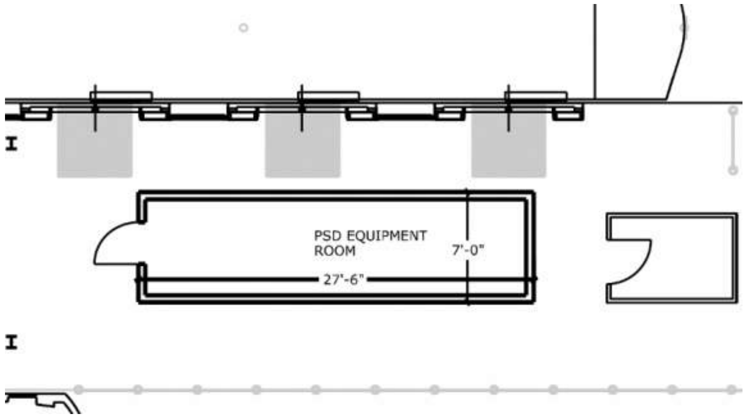

***Figure 1** – Equipment Room detail*
Queensboro Plaza Station

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

The platform edges were reconstructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.6. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

- Southbound (lower) platform: All columns are 26" from the Hudson Yards platform edge.
- Northbound (upper) platform: All columns are 51" from the platform edge.

These obstructions do not present an impediment to the installation of APGs.

Lighting:

Existing lighting: There are Linear fluorescent fixtures mounted approximately 1' from platform edge for southbound and centered under canopy on the northbound platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity (only from the Normal service) to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	Queensboro Plaza
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	118.4
Apparent Power (kVA)	148.0
Station Peak Demand Load, Max Current, (A)	411.1
Maximum Amount of Doors	146.0
PSD Total Load Including All Miscellaneous Loads, (A)	315.0
Total Load (Station Peak + PSD), (A)	726
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	74
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**. Total doors: 146. {'W'-80 + '7'-66}

***Table1**- Power Capacity Analysis (Normal Service)*

Station Power Capacity Analysis

Station Name	Queensboro Plaza
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	163.2
Apparent Power (kVA)	204.0
Station Peak Demand Load, Max Current, (A)	566.7
Maximum Amount of Doors	146.0
PSD Total Load Including All Miscellaneous Loads, (A)	315.3
Total Load (Station Peak + PSD), (A)	882
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for Reserve **service**. Total doors: 146. {'W'-80 + '7'-66}

***Table 2**- Power Capacity Analysis (Reserve Service)*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.1M to install APGs (See Appendix E).

Appendices: Table of Contents

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

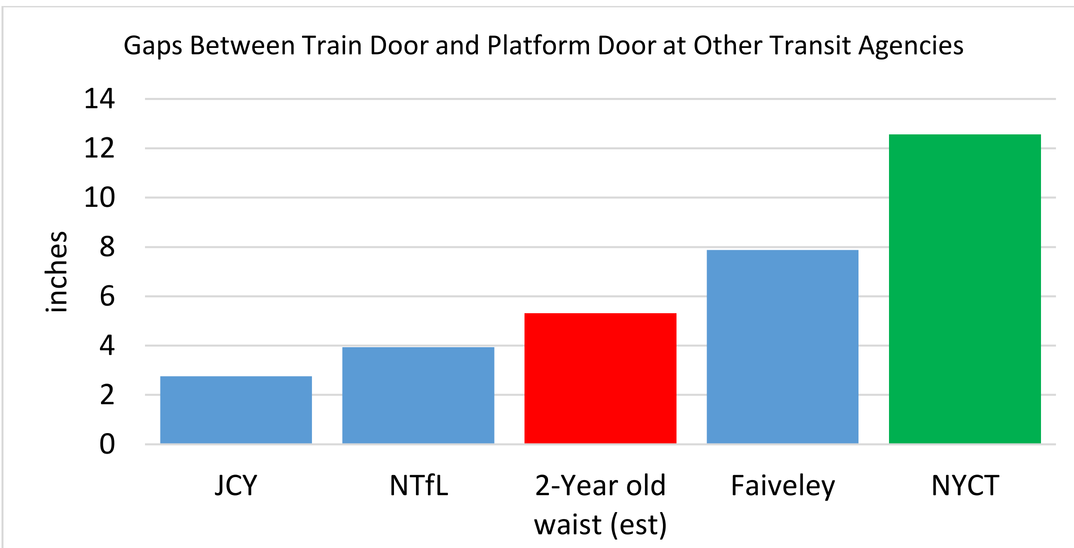

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

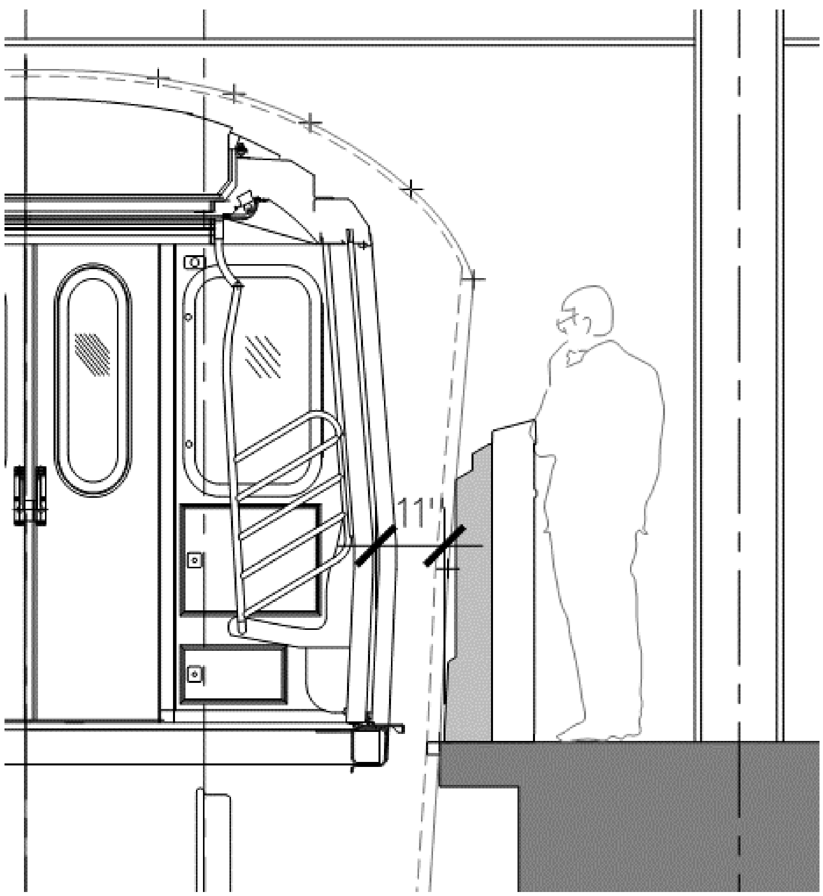

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

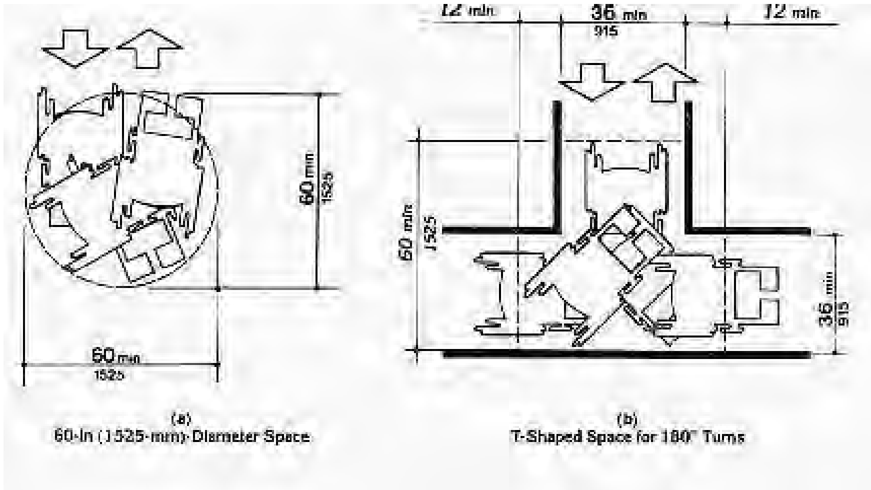
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

> *Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.*

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36” which may be constricted to 32” at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

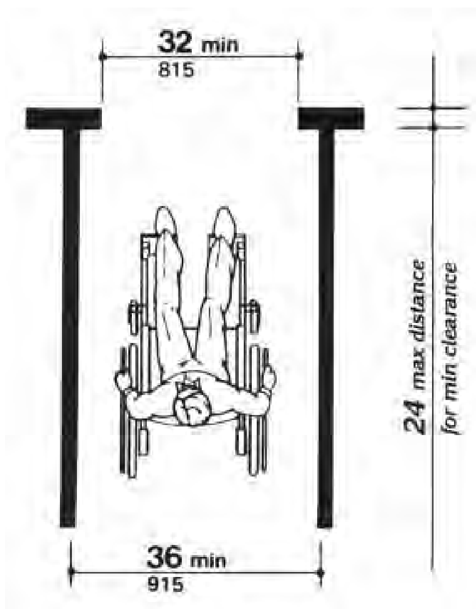


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

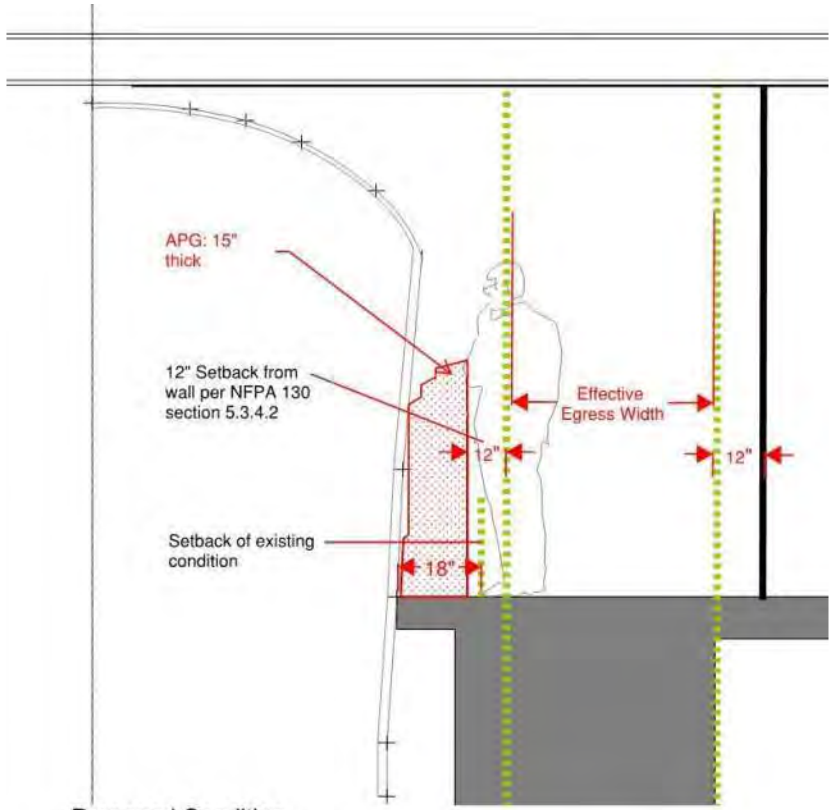
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.

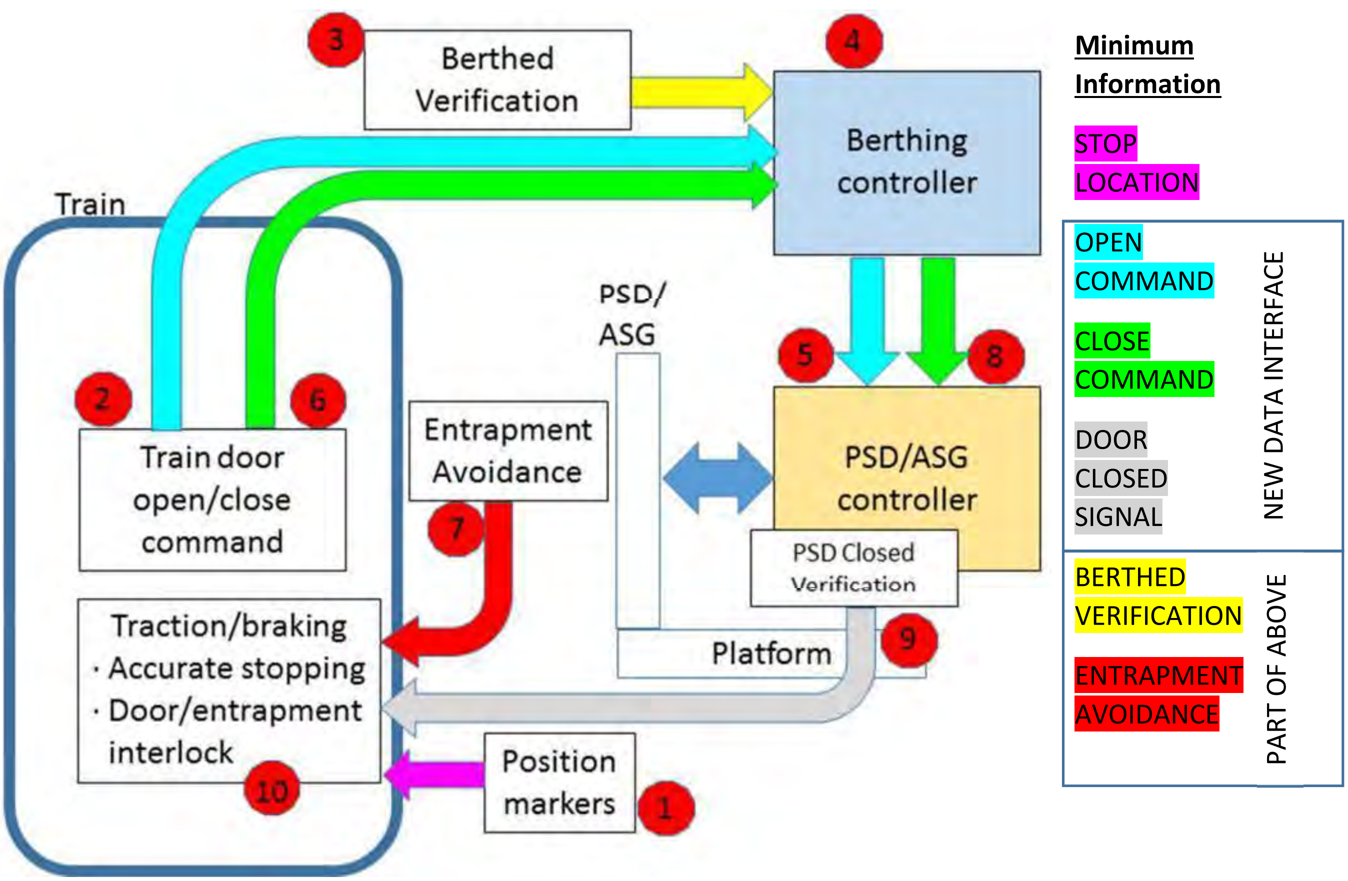

Table of Contents
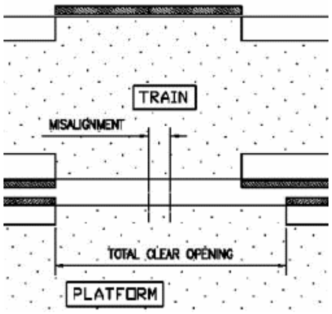
Appendix Table of Contents

Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

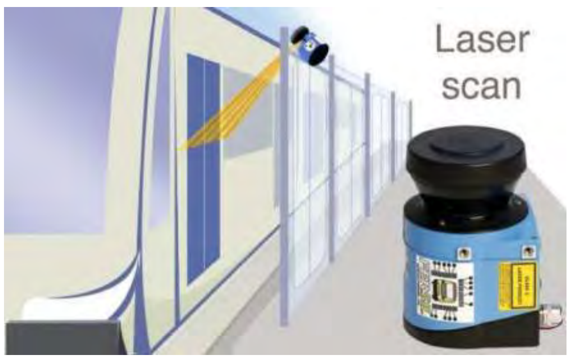
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

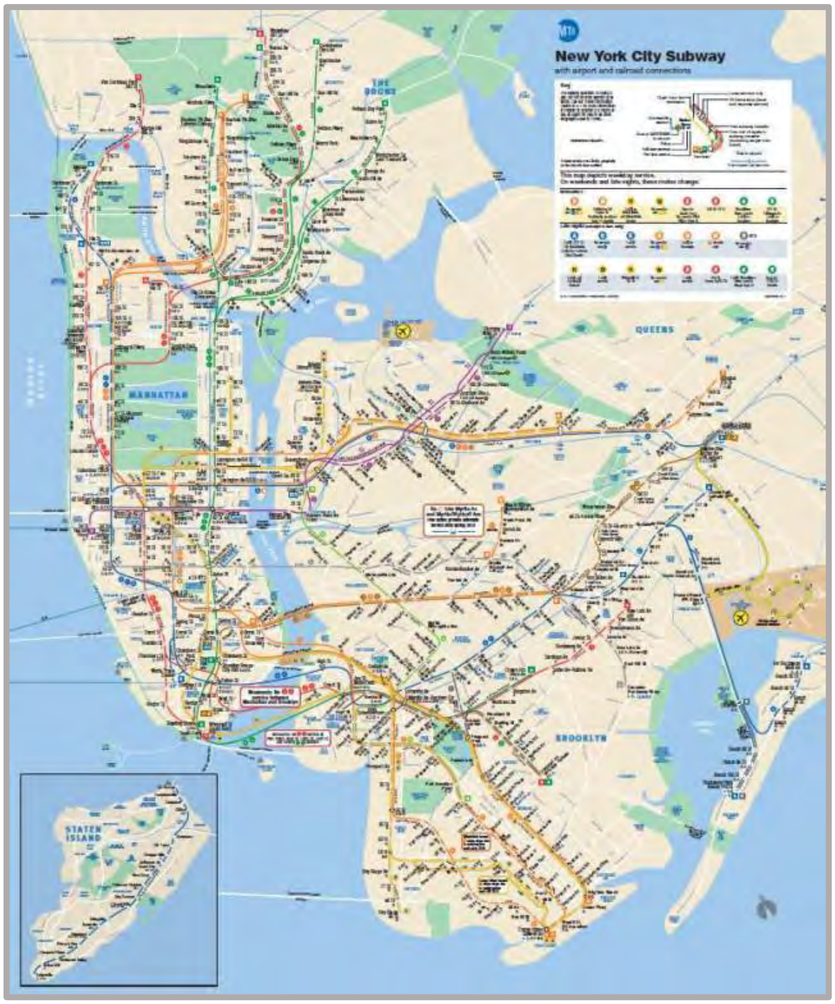


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

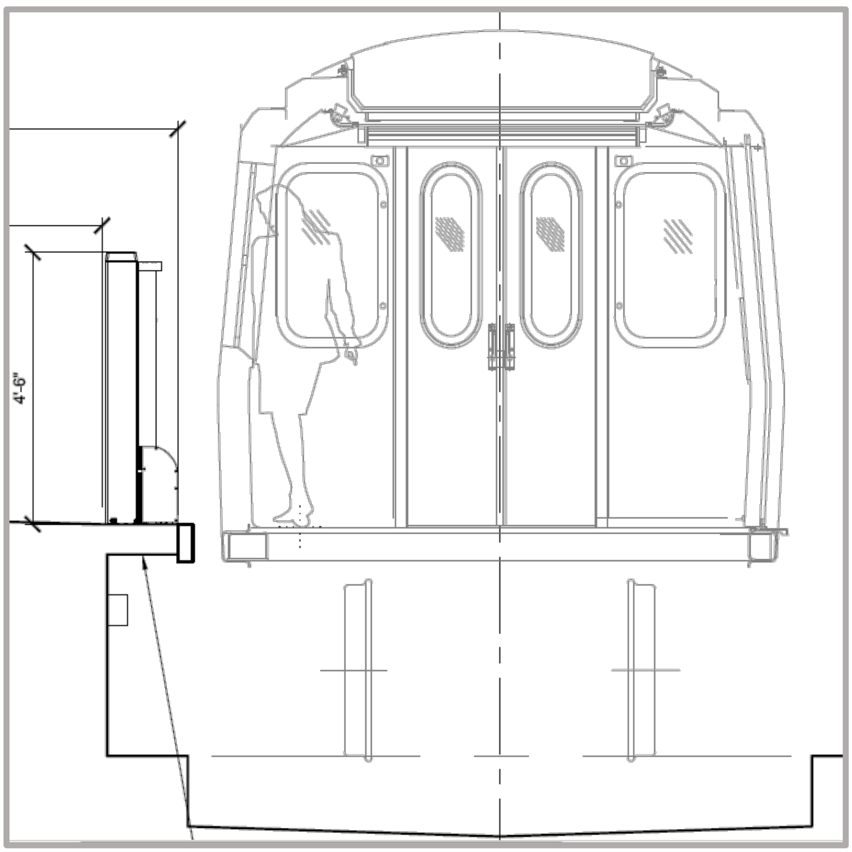

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

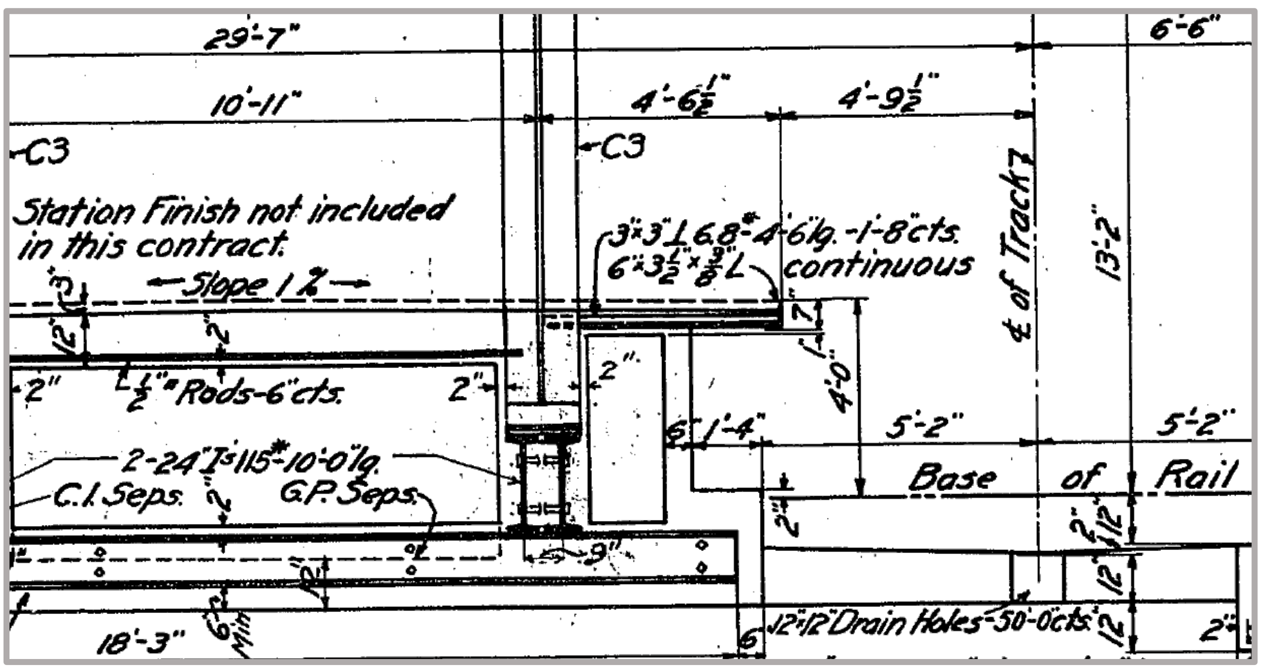

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

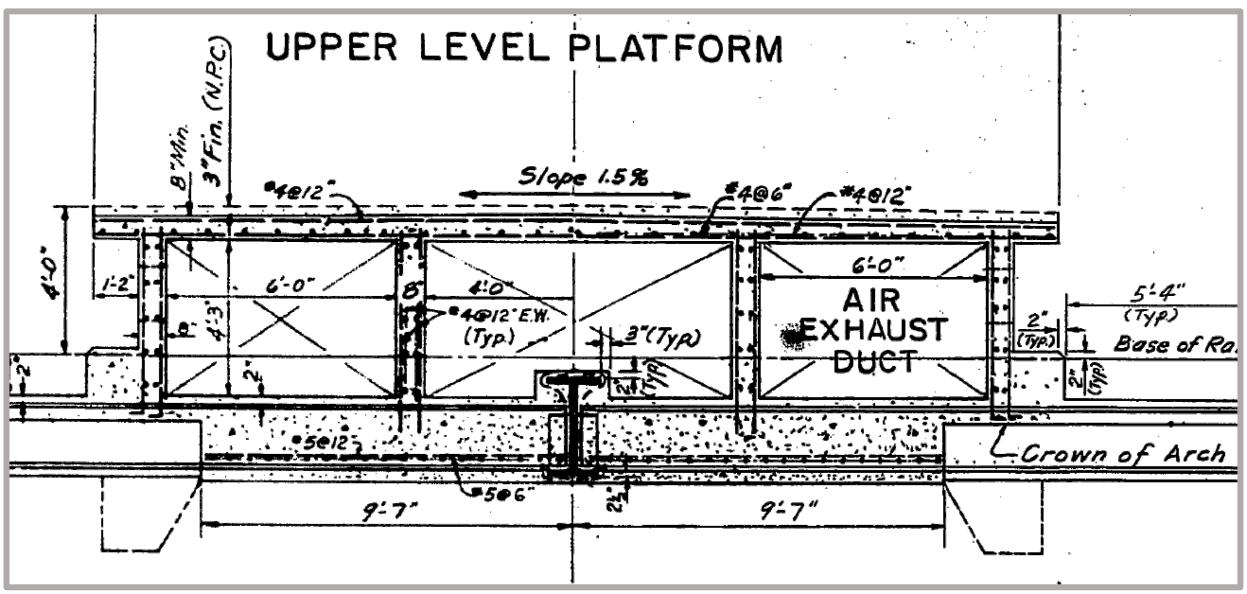

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

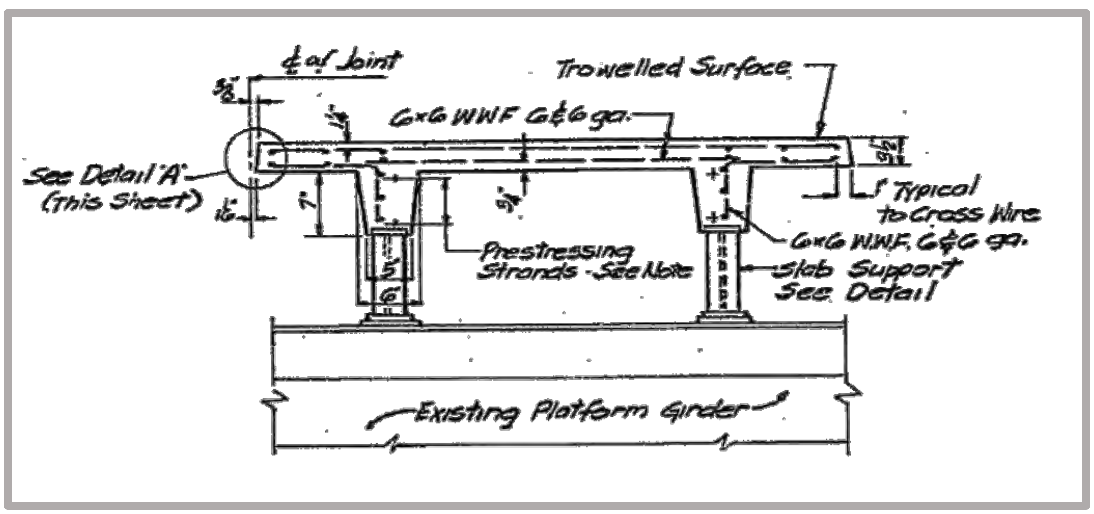

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

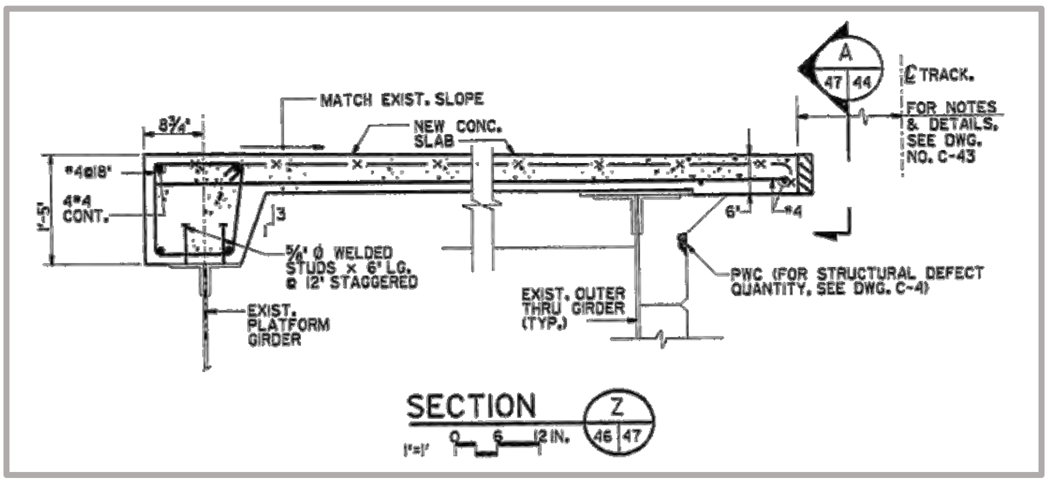

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

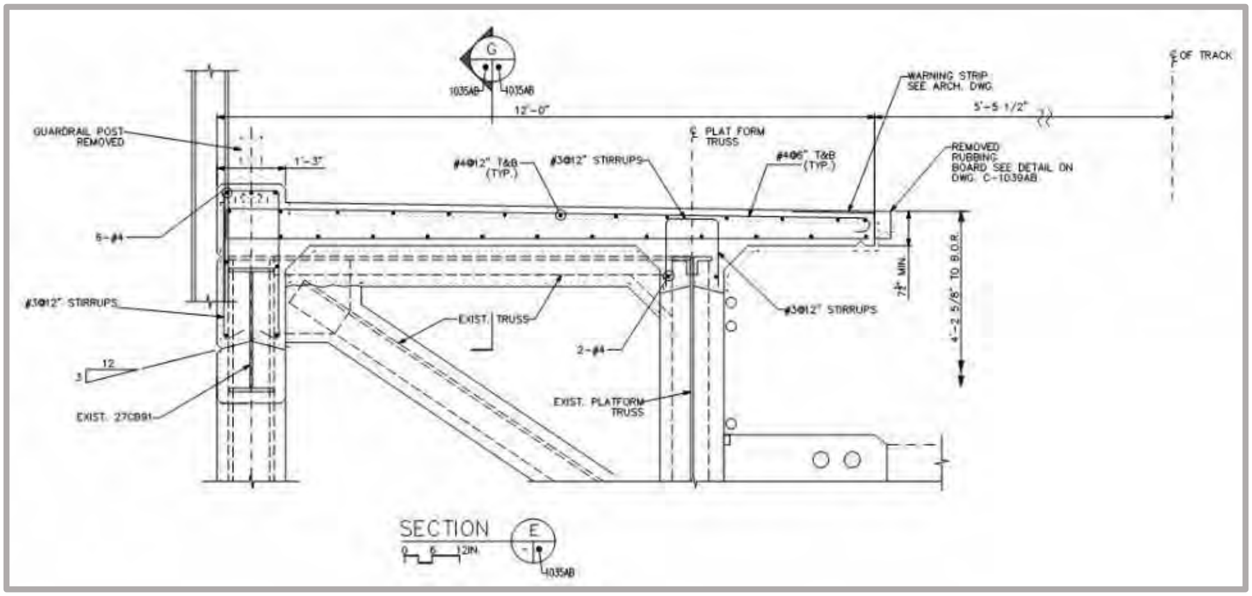

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

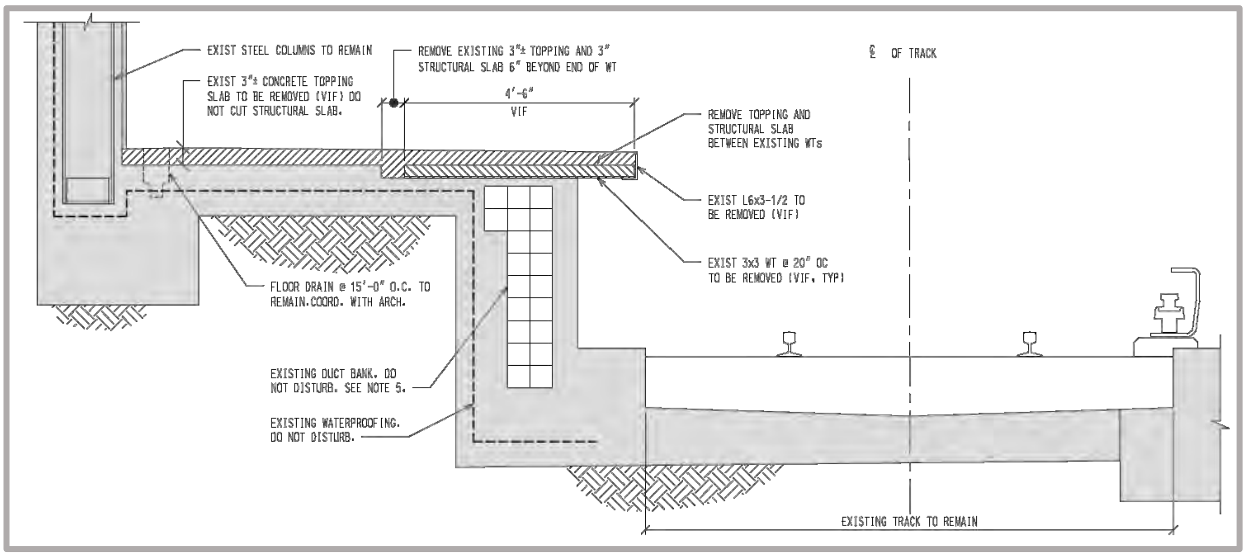

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

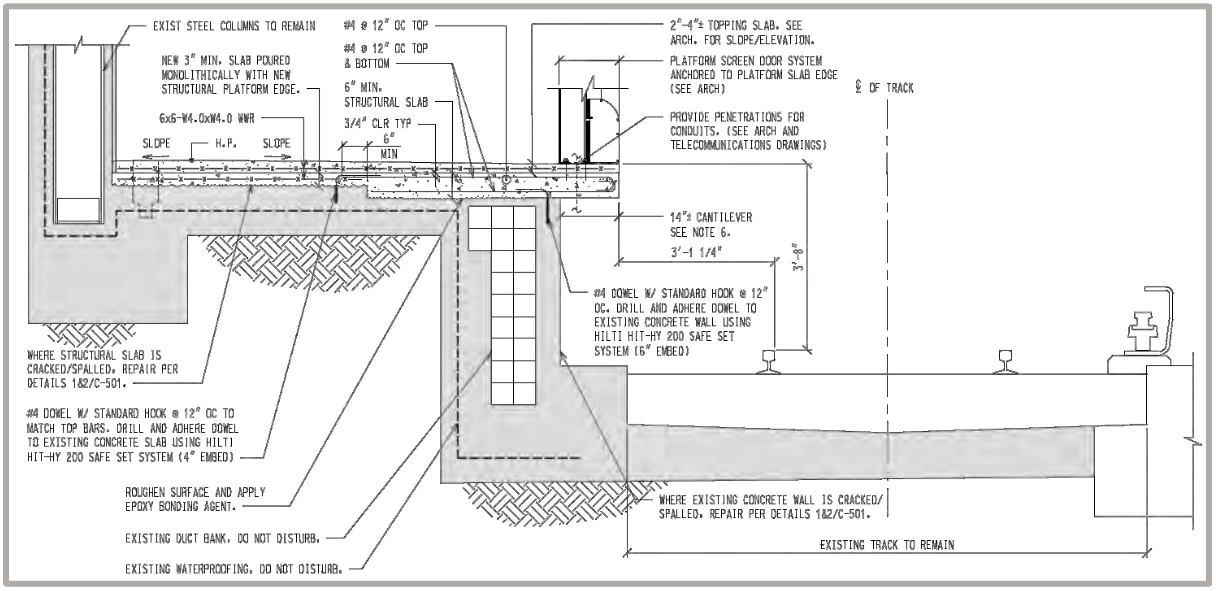

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

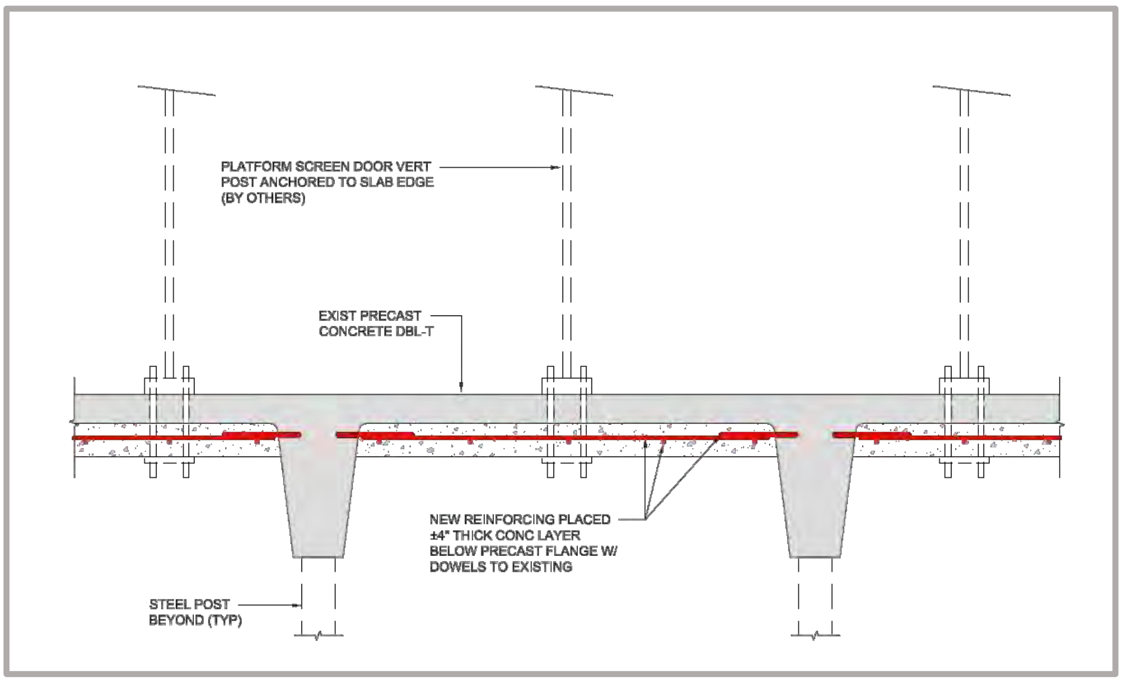

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Emergency Egress Width Analysis

MAINTENANCE, INSPECTION & REPAIR CONTRACT
PLATFORM SCREEN DOOR PILOT PROJECT
3RD AVENUE STATION ON THE CANARSIE LINE

April 12, 2018

CONFIDENTIAL

PRICING SCHEDULE WITH OPTION FOR EXTENDED TERM OF MAINTENANCE / SOFTWARE SUPPORT

ITEM NO.	DESCRIPTION	ESTIMATE QUANTITY	RATE	EXTENDED AMOUNT	SUB-TOT 01 OPTION 3.2	SUB-TOT 01 OPTION 3.1
1	First 90 days - 24-7 full time presence on site (including daily cleaning of glass)	90	$ 4,800 per Day	$ 432,000		
	Materials and labor for preventative maintenance and remedial repair performed as needed, 24/7, for the platform screen door system and ancillary equipment. Price for year 1 is intended for preventive maintenance since remedial maintenance and repairs will be covered by the warranty period. Should warranty period be longer for the System or some of its components, price should not include items covered by warranty.	9	$ 63,500 per month [Year 01]	$ 571,500		
		12	$ 83,590 per month [Year 02]	$ 1,003,080		
		12	$ 65,683 per month [Year 03]	$ 788,196	$ 2,794,776	$ 2,794,776
2	Training for 100 workers - 20 / session; 16 HRS per session	5	$ 13,000 per session	$ 65,000	$ 65,000	$ 65,000
3.1	Optional Maintenance for years 4 & 5 (OPTION 1)	Year 4-5				
	Materials and labor for preventative maintenance and remedial repair performed as needed, 24/7, for the platform screen door system and ancillary equipment.	12	$ 68,310 per month [Year 04]	$ 819,724		$ 819,724
		12	$ 71,043 per month [Year 05]	$ 852,513		$ 852,513
3.2	Optional Maintenance for years 4 & 5 (OPTION 2)	Year 4-5				
	Repair and Replacement of Defective Hardware	24	$ 6,350 per month	$ 76,200		
	Technical Assistance [4 Hrs per Month]	24	$ 880 per month	$ 10,560		
	As Needed On-Site Support [1 Day per Month]	192	$ 220 per Hour	$ 2,640		
	Software / Firmware Support	2	$ 3,500 per Year	$ 42,000	$ 131,400	$ -
4	Optional Maintenance for years 6-10	Year 6-10				
	Repair and Replacement of Defective Hardware	60	$ 9,525 per month	$ 571,500		
	Technical Assistance [4 Hrs per Month]	60	$ 920 per month	$ 55,200		
	As Needed On-Site Support [1 Day per Month]	480	$ 230 per Hour	$ 110,400		
	Software / Firmware Support	5	$ 3,750 per Year	$ 18,750	$ 755,850	$ 755,850
5	Optional Maintenance for years 11-15	Year 11-15				
	Repair and Replacement of Defective Hardware	60	$ 12,700 per month	$ 762,000		
	Technical Assistance [5 Hrs per Month]	60	$ 1,200 per month	$ 72,000		
	As Needed On-Site Support [1.5 Days per Month]	720	$ 240 per Hour	$ 172,800		
	Software / Firmware Support	5	$ 4,000 per Year	$ 20,000	$ 1,026,800	$ 1,026,800
6	Optional Maintenance for years 16-20	Year 16-20				
	Repair and Replacement of Defective Hardware	60	$ 15,875 per month	$ 952,500		
	Technical Assistance [6 Hrs per Month]	60	$ 1,500 per month	$ 90,000		
	As Needed On-Site Support [2 Days per Month]	960	$ 250 per Hour	$ 240,000		
	Software / Firmware Support	5	$ 4,500 per Year	$ 22,500	$ 1,305,000	$ 1,305,000
	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 2) [DEFAULT OPTION AS PER RFP DOCUMENTATION]		TOTAL:	$ 6,078,826	$ 6,078,826	$ 7,619,663

	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 1)		TOTAL:	$ 7,619,663

7	Labor Bill Rate (per hour)	Year 1	$ 238 per hour *	
	Task Orders (Rate in Effect 24/7/365)	Year 2	$ 248 per hour *	
		Year 3	$ 257 per hour *	
	Optional :	Year 4	$ 268 per hour *	
	Optional :	Year 5	$ 278 per hour *	

Note: Labor rate is deemed to include all relevant tax and insurance, medical, pension, vacation fund, etc., travel time to and from project site and night/shift/weekend/holiday work i.e. 24/7 Rate

* Labor rates include Contractor's Overhead & Profit and Insurance (Refer Annual Maintenance Cost Breakdown) and are escalated at 4% per annum

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

MTA/NYCT

January 7, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

MTA/NYCT

January 7, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : DEKALB AVENUE FLATBUSH AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	679	LF		
5	LENGTH OF THE PLATFORM EDGE =	654	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,333**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,333	LF	7	9,331
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,665	SF	12	79,980
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	134	CY	2,500	335,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,335	EA	25	33,375
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,335	EA	25	33,375
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,333	LF	95	126,635
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,333	LF	15	19,995
26	Remove existing platform tiles	1,333	LF	12	15,996
27	Sawcut existing topping concrete at perimeter of removal area	1,333	LF	5	6,665
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,998	SF	8	63,984
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,333	SF	15	19,995

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : ATLANTIC AVE. BARCLAYS CTR.

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	618	LF		
5	LENGTH OF THE PLATFORM EDGE =	618	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,236**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,236	LF	7	8,652
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,180	SF	12	74,160
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,238	EA	25	30,950
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,238	EA	25	30,950
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,236	LF	95	117,420
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,236	LF	15	18,540
26	Remove existing platform tiles	1,236	LF	12	14,832
27	Sawcut existing topping concrete at perimeter of removal area	1,236	LF	5	6,180
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,416	SF	8	59,328
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,236	SF	15	18,540

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : FORT HAMILTON PKWY

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	625	LF		
5	LENGTH OF THE PLATFORM EDGE =	678	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,303**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10

7-Jan-19

STATION : BAY PKWY

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	686	LF		
5	LENGTH OF THE PLATFORM EDGE =	705	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,391**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,391	LF	7	9,737
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,955	SF	12	83,460
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	140	CY	2,500	350,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,393	EA	25	34,825
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,393	EA	25	34,825

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : CONEY ISLAND

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	615	LF		
5	LENGTH OF THE PLATFORM EDGE =	616	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,231**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,231	LF	7	8,617
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,155	SF	12	73,860
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,233	EA	25	30,825
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,233	EA	25	30,825
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,231	LF	95	116,945
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,231	LF	15	18,465
26	Remove existing platform tiles	1,231	LF	12	14,772
27	Sawcut existing topping concrete at perimeter of removal area	1,231	LF	5	6,155
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,386	SF	8	59,088
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Platform width i.e. 27'-6" wide strip	620	SF	8	4,960
30	New Work				
31	New concrete topping to match existing	1,231	SF	15	18,465

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : 5TH AVE./59TH ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	615	LF		
5	LENGTH OF THE PLATFORM EDGE [ASTORIA BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,230	LF	7	8,610
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,230	LF	95	116,850
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
26	Remove existing platform tiles	1,230	LF	12	14,760
27	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,230	SF	15	18,450

Tier 2-3 Report on Feasibility of Platform Edge Barriers for N - Line Stations

7-Jan-19

STATION : 49TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	703	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	703	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,406**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,406	LF	7	9,842
14	Remove 5' wide section of 3" deep structural slab to platform edge	7,030	SF	12	84,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	142	CY	2,500	355,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,408	EA	25	35,200
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,408	EA	25	35,200
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,406	LF	95	133,570
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,406	LF	15	21,090
26	Remove existing platform tiles	1,406	LF	12	16,872
27	Sawcut existing topping concrete at perimeter of removal area	1,406	LF	5	7,030
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,436	SF	8	67,488
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	320	SF	8	2,560
30	New Work				
31	New concrete topping to match existing	1,406	SF	15	21,090

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'Q' SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: June 24, 2019

STV 100 Years

Table of Contents

Appendices

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 34 newly evaluated stations, 26 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic

upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the Q-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 23% of the 'Q' Line Stations. Total implementation cost would be $253.2 for APGs and $240.3M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 8 feasible stations, the aggregate annual maintenance cost would be $7.4M.

Summary Table

(23% Feasible 8/34)

MRN No.	Station Names	Station Type	Platform Type	Feasibility	Issues/Reason for Failure	Cost APGs	Cost PSDs
009	57th Street 7th Ave	SUB	Island	No	ADA Clearance	-	-

					TOTAL	$253.2M	$240.3M

1.0 Station Assessments

1.01 – MR 009 | 57th Street 7th Avenue Station

Summary: *57th Street 7th Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the center stairs as the remaining width would be 27" (see figure 1).*

Description

The 57th Street Station is an underground station consisting of two center / island platforms. The platforms are approximately 19'-8" wide. The platforms are straight with two rows of columns at 42" from the edge of the platform. At four staircases columns flank the stair. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA dimension*
57th Street Station

1.02 – MR 010 | 49th Street Station

Summary: *49th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 49th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns on the platforms. The platform width varies from approximately 7'-0" to 14'-8". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located as a split room, with one at the south control area of the southbound, and one located at the north control area of the southbound. (see **Figure 1, Figure 2**). The proposed room dimension are 16'-0" x 7'-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Existing lighting: Throughout both platforms; linear fluorescent; perpendicular to the platform edge mounted in the ceiling coffers. No lighting reconfiguration will be required as part of a PSD installation.

***Figure 3** – General platform view*
49th Street Station

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	49th Street
Peak Demand Load from ConEd Report, Last **12** Months, (kW)	45.2
Apparent Power (kVA)	56.5
Station Peak Demand Load, Max Current, (A)	156.9
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	352
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	449
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. Meter reading is for 12 months.

Table 1. Power Capacity Analysis (Normal Service)

Power Capacity Analysis (Reserve Service)

Station Name	49th Street
Peak Demand Load from ConEd Report, Last **12** Months, (kW)	27.2
Apparent Power (kVA)	34.0
Station Peak Demand Load, Max Current, (A)	94.5
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	289
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	511
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. Meter reading is for 12 months.

Table 2. Power Capacity Analysis (Reserve)

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.5M to install APGs and $43.5M to install PSDs (See Appendix E)

Table of Contents

1.03 – MR 011 | Times Square / 42nd Street Station

Summary: *Times Square / 42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 19" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the Shuttle, 7, 1,2,3-line for the remainder of the station)*

Description

Times Square / 42nd Street Station is a below-grade station consisting of two center / island platforms. The platform width is 19-4" throughout. The platforms are straight with two rows of columns at 3'-8" from edge of platform. At the south end of the platforms, the columns flanking an equipment room are 2'-10" from the platform edge. The implementation of a platform edge barrier would reduce this width to 19" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** –platform*
42nd Street / Times Square Station

1.04 – MR 012 | 34th Street / Herald Square Station

Summary: *34th Street / Herald Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see the B, D, F, M-line report for the remainder of the station)*

Description

34th Street / Herald Square Station is a below-grade station consisting of two center / island platforms. The platform width is 19-8" throughout. The platforms are straight with two rows of columns at 3'-4" from edge of platform. On the center / island platform the columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
34th Street Station

1.05 – MR 013 | 28th Street Station

Summary: *28th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

28th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-6" from the platform edge at each platform, though approximately one third of the platform is column-free. The platform width varies from 6'-0" to 9'-5. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar..

.

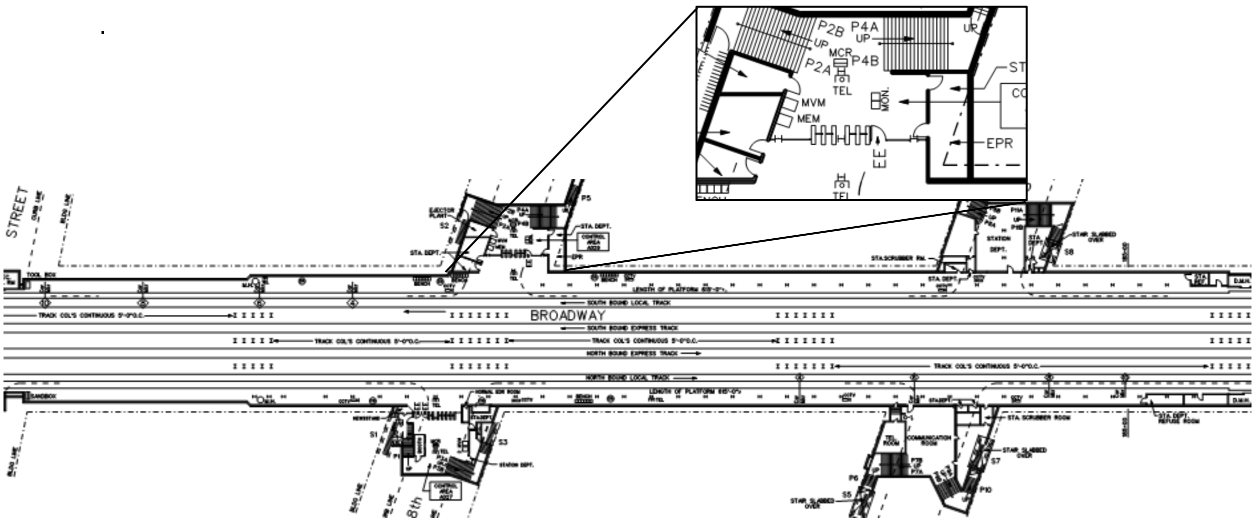

Figure 1 *– Station Plan- 28th Street Station*

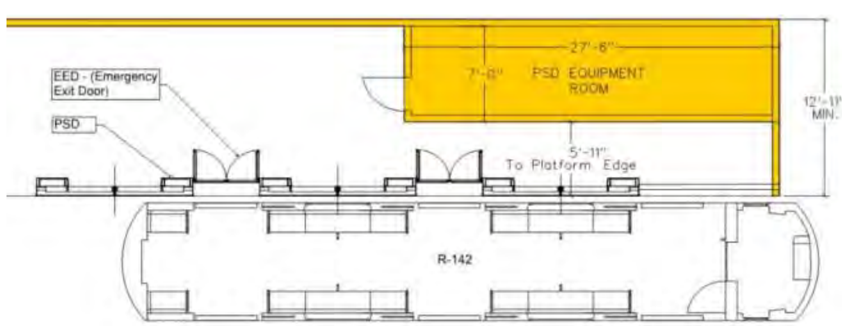

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.06 – MR 014 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the northbound platform control area as the remaining width would be 27" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-8" from the platform edge at each platform. The platform width varies from 6'-0" to 11'-2" in width. The entry / exit turnstiles at the south entrance of the northbound platform are positioned with minimal clearance of 18" to the adjacent columns. The remaining space between the columns and the platform edge measures 42". The implementation of a platform edge barrier would reduce this width to 27" or less which would not allow for ADA compliant wheelchair movement. See figures 1and 2 below. The plan in figure 1 demonstrates that there is no alternative location for the turnstiles / railings.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

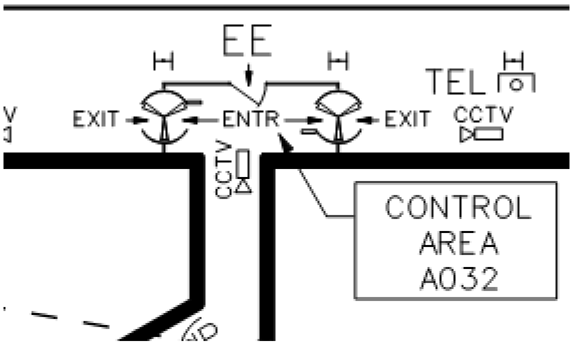

Figure 1 *– Non-Compliant ADA condition - 23rd Street*

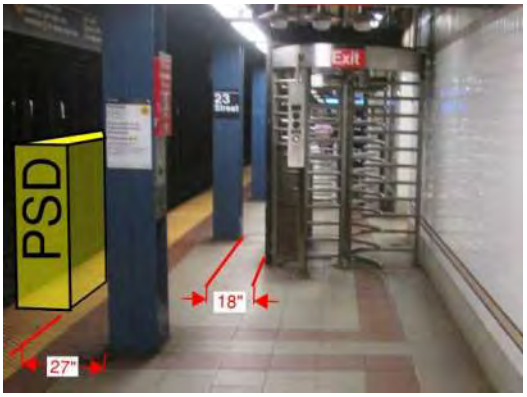

Figure 2 *– Non-Compliant ADA condition - 23rd Street*

1.07 – MR 015 | 14th Street / Union Square Station

Summary: *14th Street / Union Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the L-line and 4,5,6-line for the remainder of this complex)*

Description

14th Street / Union Square Station is a below-grade station consisting of two center / island platforms. The platform width is 18-8" throughout. The platforms are straight with two rows of columns at 3'-6" from edge of platform; these columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
14th Street / Union Square

Table of Contents

1.08 – MR 016 | 8th Street Station

Summary: 8th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).

Description

8th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-4" from the platform edge at each platform. The platform width varies from 9'-6" to 11'-0" in width. The south street stair at each platform is positioned with minimal clearance to the adjacent columns. The remaining space between the columns and the platform edge measures 40". The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
8th Street Station

1.09 – MR 017 | Prince Street Station

Summary: *Prince Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

Prince Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-6' to 8'-8". Platform width at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width to 21" or less below the required minimum of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
Prince Street

Table of Contents

1.10 – MR 019 | Canal Street Station Lower Level

Summary: *Canal Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Canal Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The typical width of the platforms ranges from 7'-0' to 9'-6". Platform widths are not wide enough to accommodate an equipment room (Figure 2) and the mezzanine cannot accommodate a full-size equipment room without constraining passenger flow.

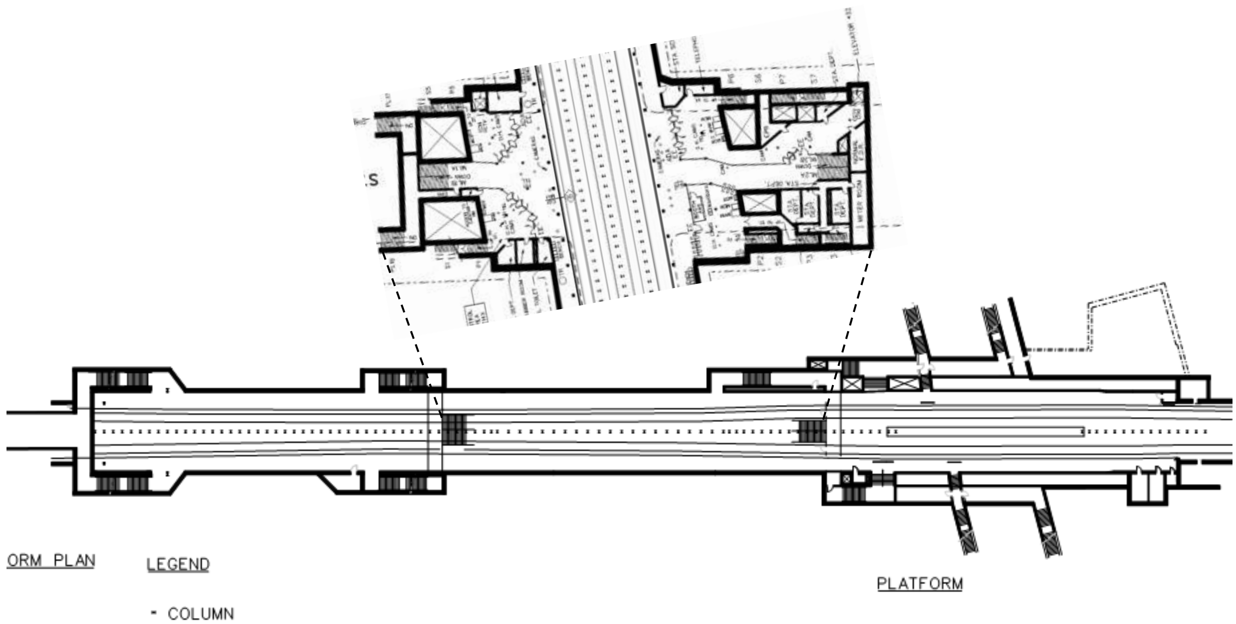

Figure 1 *– Station layout showing lack of space*
Canal Street Station Lower Level – Mezzanine shown above

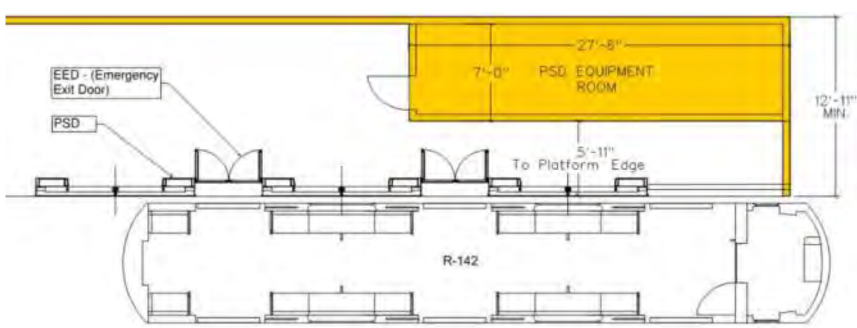

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.11 – MR 026 | Dekalb Ave Station

Summary: *Dekalb Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

Dekalb Ave Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. The platform columns are spaced 10'-10" on center, and column faces typically measure 3'-8" from the platform edge. The platform width is 15'-8" throughout. At the platform staircases, the columns flanking the stairs measure 3'-8" from the platform edge and are touching the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 44" to 29" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

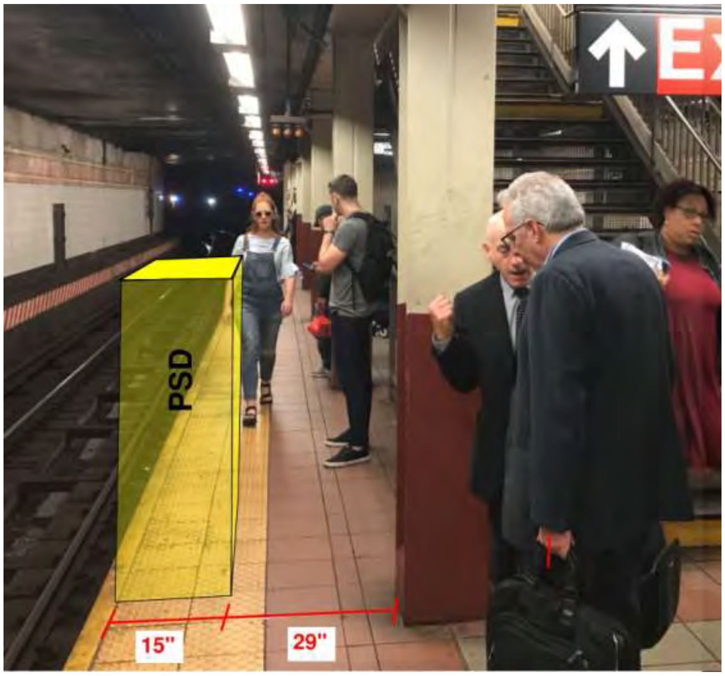

Figure 1 *– Non-Compliant ADA condition Dekalb Avenue Station*

Table of Contents

1.12 – MR 040 | Atlantic Avenue Barclay Center Station

Summary: *Atlantic Avenue Barclay Center Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 8" (see figure 1).*

Description

The Atlantic Avenue Barclay Center Station is a below-grade station with one center / island platform. The platform structure is cast-in-place concrete. There are two rows of columns which lie 23" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum pinch point width of 32". The remaining 8" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

***Figure 1** – Non-compliant ADA condition*
Atlantic Avenue Barclay Center Station

1.13 – MR 041 | 7th Avenue Flatbush Avenue Station

Summary: *7th Avenue Flatbush Avenue Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would prohibit the installation of a 15"-wide PSD system.*

Description:

7th Avenue Flatbush Avenue Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
7th Avenue Flatbush Avenue Station

1.14 – MR 042 | Prospect Park

Summary: *Prospect Park Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Prospect Park Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms at the north end is 3'-10". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

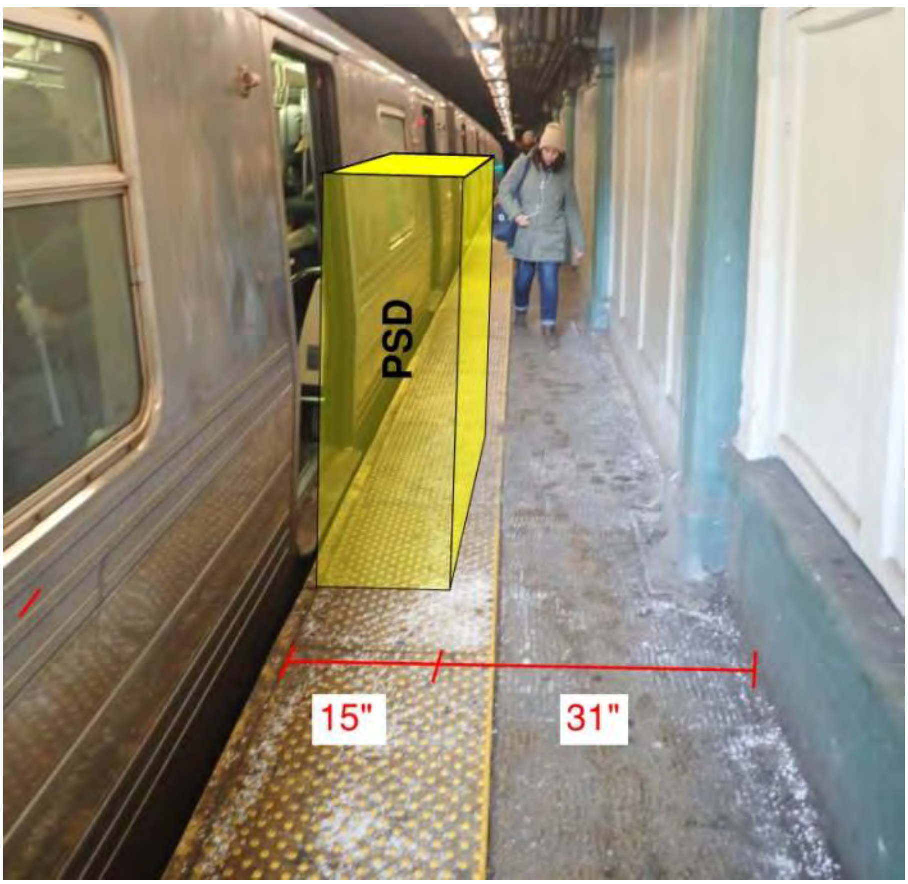

Figure 1 *– Non-compliant ADA condition*
Prospect Park Station

1.15 – MR 043 | Parkside Avenue Station

Summary: *Parkside Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

The Parkside Avenue Station is an open cut station with two curved side platforms. The platform structures are cast-in-place concrete. The corridor width at the platform staircases is 3'-2". The implementation of a platform edge barrier would reduce this width below the required minimum corridor width of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Area of ADA non-compliance*
Parkside Avenue Station

1.16 – MR 044 | Church Avenue Station

Summary: *Church Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 15" (see figure 1).*

Description

The Church Avenue Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The corridor width adjacent to the station department room is 2'-6". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement.. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Church Avenue Station

Table of Contents

1.17 – MR 045 | Beverly Road Station

Summary: *Beverly Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

The Beverly Road Station is an open cut station with two curved side platforms. The platform structures are cast-in-place concrete. The columns at the platform stairs are 2'-4" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum pinch point width of 32". The remaining 13" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Beverly Road Station

1.18 – MR 046 | Cortelyou Road Station

Summary: *Cortelyou Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

The Cortelyou Road Station is an open cut station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the north end of the southbound platform is 3'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Cortelyou Road Station

Table of Contents

1.19 – MR 047 | Newkirk Plaza Station

Summary: *Newkirk Plaza Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

The Newkirk Plaza Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The pinch point width at platform columns at staircases is 2'-4". The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 13" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

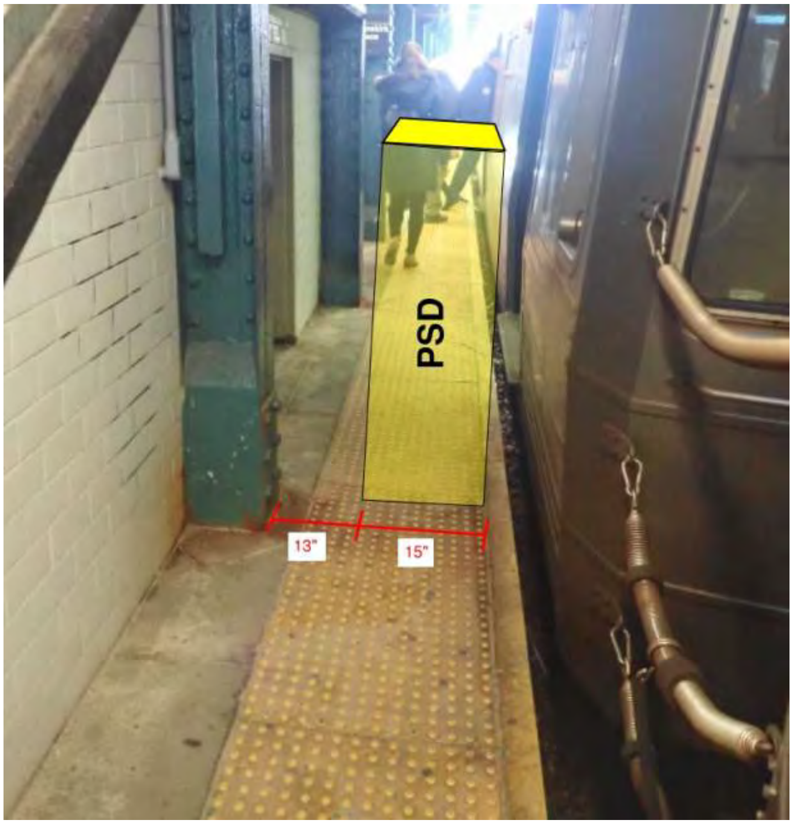

***Figure 1 –** Area of ADA non-compliance*
Newkirk Plaza Station

Table of Contents

1.20 – MR 048 | Avenue H Station

Summary: *Avenue H Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 5'-8" (see figure 1).*

Description

Avenue H Station is an embankment station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-6' to 8'-2". The southbound platform in photo below, is 5'-8" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
Avenue H Station

Table of Contents

1.21 – MR 049 | Avenue J Station

Summary: *Avenue J Station is feasible for APGs only. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Avenue J Station is an embankment station with two straight side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. A canopy covers approximately one half of the platform length. The platforms are almost entirely column-free. The platform widths range from 6'-6" to 7-8" throughout. Ceiling heights at the canopy measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs are infeasible at outdoor stations outside of the canopy area, as they do not have a structure to support the top of the barriers.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the south end of the southbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

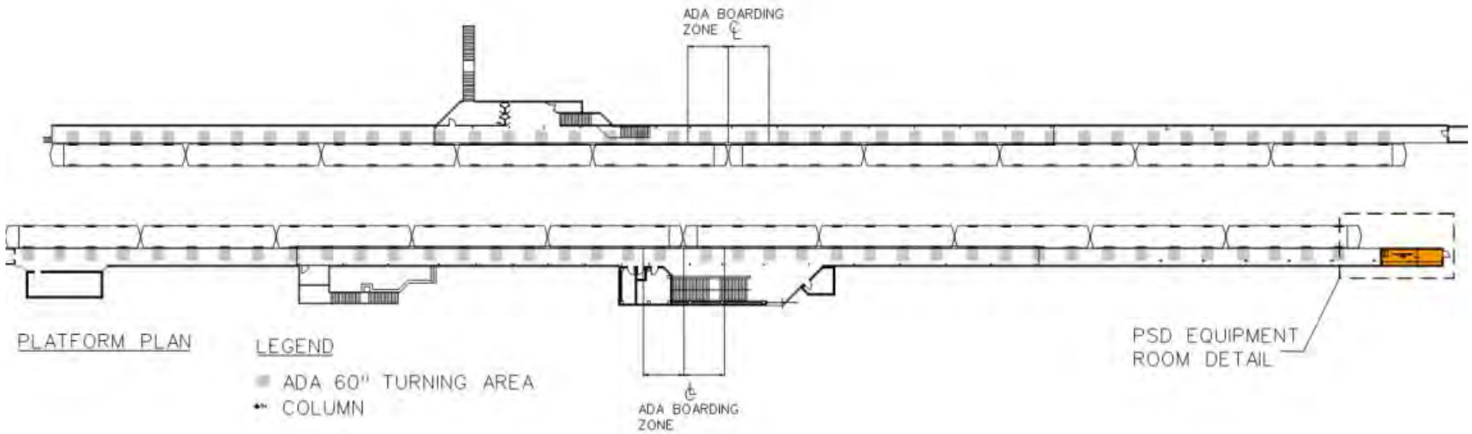

***Figure 1** – Overall Station Plan*
Avenue J Station

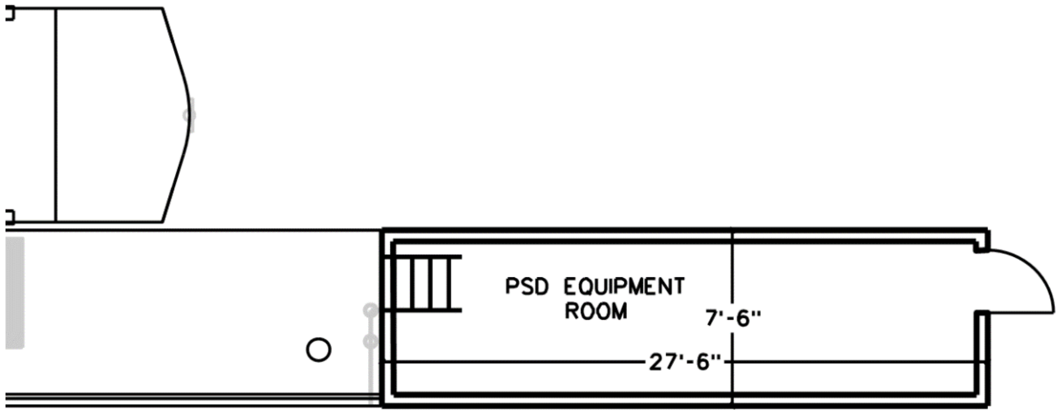

***Figure 2** – PSD Equipment Room Detail*
Avenue J Station

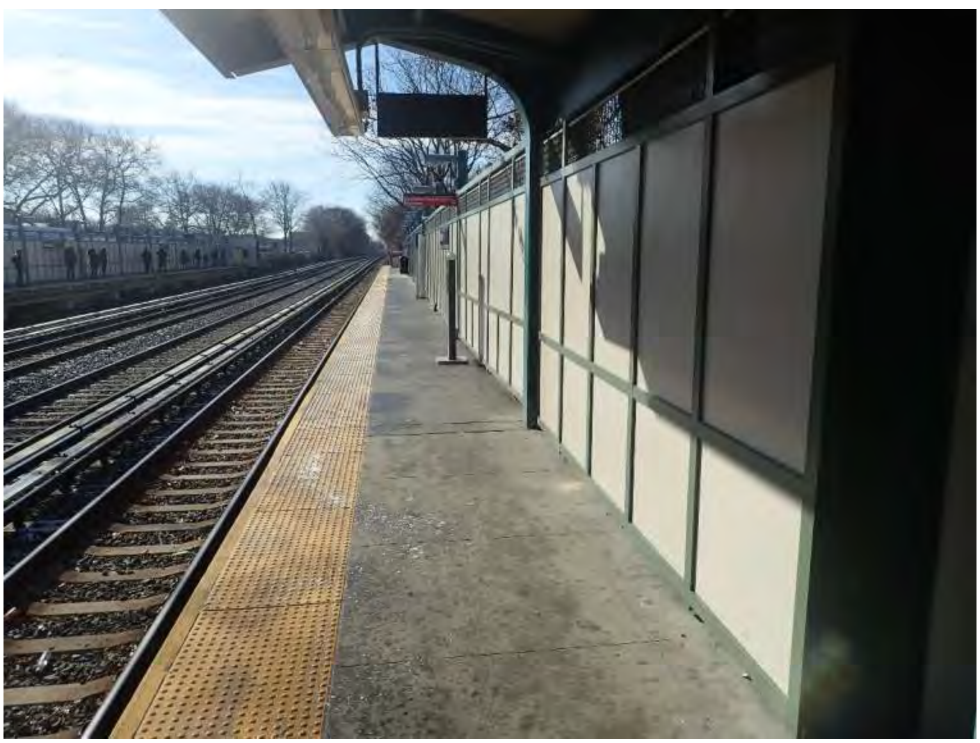

***Figure 3** – Typical platform view*
Avenue J Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout both platform canopy areas there are linear florescent fixtures mounted parallel to the platform edge. Outside of the canopy areas there are point source lights mounted on the windscreens. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & 2 see the Power Capacity Analysis for this station.

Station

Power Capacity Analysis (Normal service)

Station Name	Avenue J
Peak Demand Load from ConEd Report, (kW)	44.0
Apparent Power (kVA)	55.0
Station Peak Demand Load, Max Current, (A)	155.8
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	350.4
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	49.6
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 400 A Service switch & Fuse. Station has (2) separate meter readings for each Normal & Reserve service. Note that the Con Ed demand data Meter readings are REVERSED. (Reserved reading indicated is actually for Normal.)

***Table 1**. Normal Service Power Capacity Analysis*

Station
Power Capacity Analysis (Reserve service)

Station Name	Avenue J
Peak Demand Load from ConEd Report, (kW)	14.4
Apparent Power (kVA)	18.0
Station Peak Demand Load, Max Current, (A)	50.0
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	245
Station Service Power Capacity, (A)	400
Service Spare Capacity, (A)	155
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 400 A Service switch and fuse. Station has (2) separate meter readings for each Normal & Reserve service. Note that the Con Ed demand data Meter readings are REVERSED. (Normal reading indicated is actually for Reserved.)

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.6M to install APGs. (See Appendix E)

1.22 – MR 050 | Avenue M

Summary: *Avenue M Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the northbound platform as the existing width is 4'-3" (see figure 1).*

Description

Avenue M Station is an embankment station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-3' to 6'-8". The northbound platform in photo below, is 4'-3" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

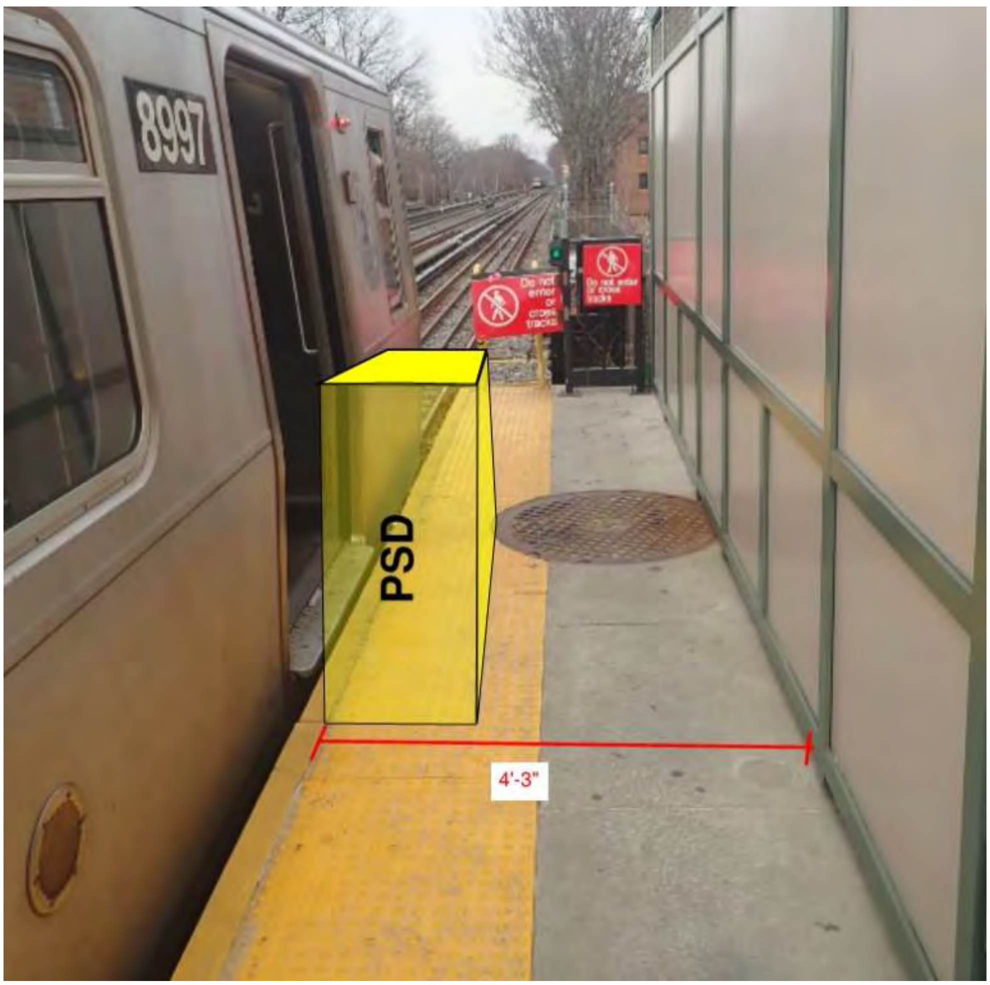

***Figure 1** – Non-Compliant egress condition*
Avenue M Station

1.23 – MR 051 | Kings Highway Station

Summary: *Kings Highway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

The Kings Highway Station is an embankment station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 15'-0". At the elevator, the clearance is 3'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Kings Highway Station

1.24 – MR 052 | Avenue U Station

Summary: *Avenue U Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Avenue U Station is an embankment station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths range from 3'-8" to 11'-6". The south end of the northbound platform is 3'-8" in width. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

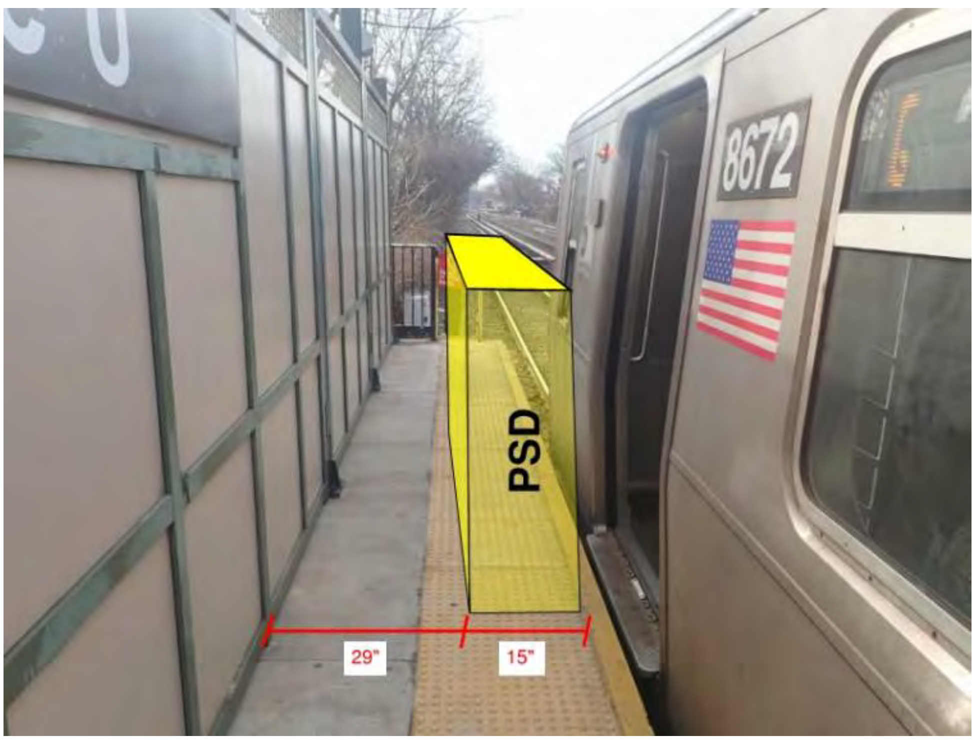

***Figure 1 –** Area of ADA non-compliance*
Avenue U Station

1.25 – MR 053 | Neck Road

Summary: *Neck Road Station is feasible for APGs only. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Neck Road Station is an embankment station with two straight side platforms (see Figure 1). The platform structures are cast-in-place concrete. The platforms are almost entirely column-free. A canopy covers approximately one third of the platform length. The platform widths range from 6'-8" to 7-0" throughout. Ceiling heights measure no less than 7'-6" in the canopy area.

Full Height PSDs: Full height PSDs are infeasible at outdoor stations outside of the canopy area, as they do not have a structure to support the top of the barriers.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the south end of the southbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'Q' Line Stations
(Neck Road Station)

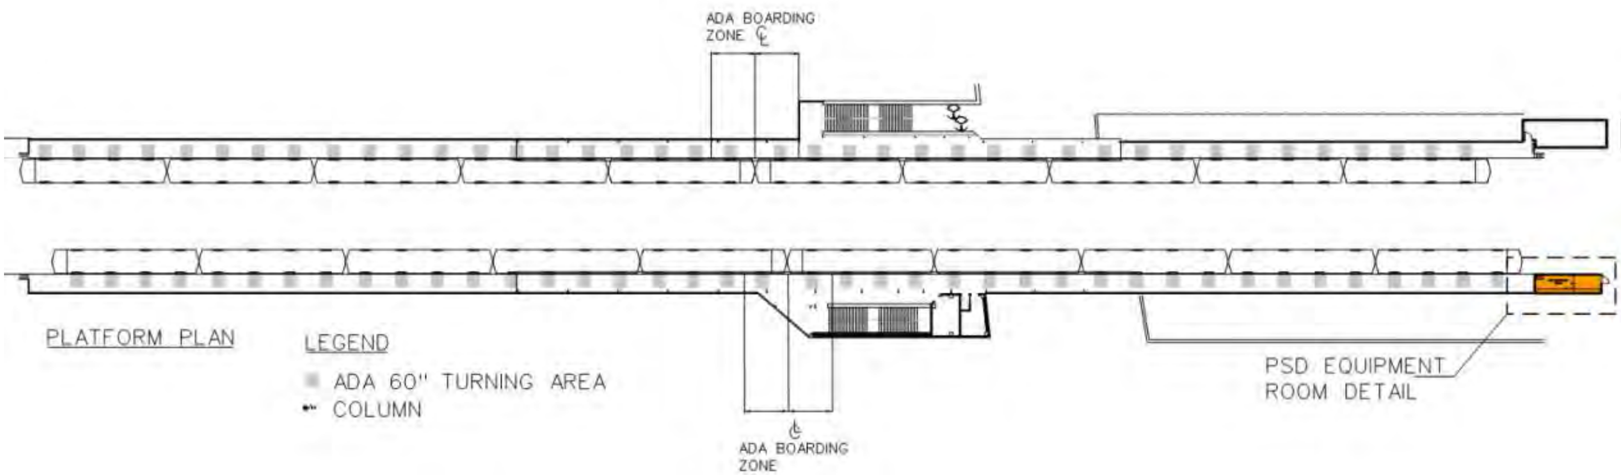

***Figure 1** – Overall Station Plan*
Neck Road Station

Table of Contents

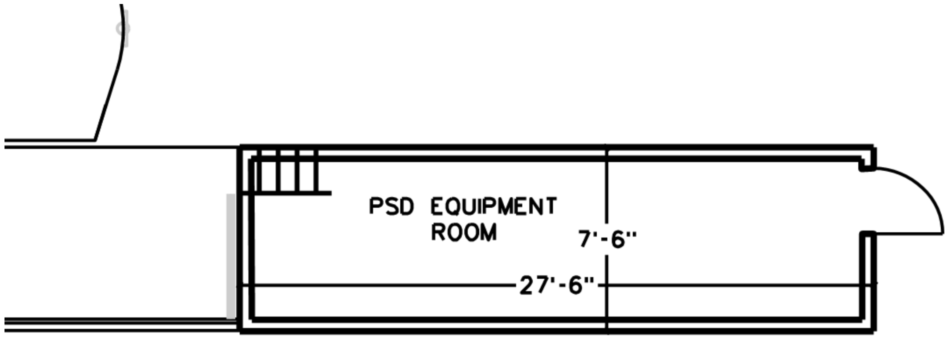

Figure 2 *– PSD Equipment Room Detail*
Neck Road Station

Figure 3 *– Typical platform view*
Neck Road Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout both platform canopy areas there are linear florescent fixtures mounted parallel to the platform edge. Outside of the canopy areas there are point source lights mounted on the windscreens. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & 2 see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal service)

Station Name	Neck Road
Peak Demand Load from ConEd Report, (kW)	4302.0
Apparent Power (kVA)	54.0
Station Peak Demand Load, Max Current, (A)	150.0
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	344.6
Station Service Power Capacity, (A)	400.0
Service Spare Capacity, (A)	55.4
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 400 A Service switch & Fuse. Station has (2) separate meter readings for each Normal & Reserve service.

Table 1. Normal Service Power Capacity Analysis

Station
Power Capacity Analysis (Reserve service)

Station Name	Neck Road
Peak Demand Load from ConEd Report, (kW)	12.8
Apparent Power (kVA)	16.0
Station Peak Demand Load, Max Current, (A)	44.4
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	239
Station Service Power Capacity, (A)	400
Service Spare Capacity, (A)	161
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 400 A Service switch and fuse. Station has (2) separate meter readings for each Normal & Reserve service.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.5M to install APGs. (See Appendix E)

1.26 – MR 054 | Sheepshead Bay Station

Summary: *Sheepshead Bay Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Sheepshead Bay Station is an elevated station with two curved center / island platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 15'-6". At the stairs, the clearance is 3'-8". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Sheepshead Bay Station

Table of Contents

1.27 – MR 055 | Brighton Beach Station

Summary: *Brighton Beach Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Brighton Beach Station is an elevated station with two curved center / island platforms. The platform structures are cast-in-place concrete. The platforms are approximately 15'-6" in width. At the four stairways, the clearance is 3'-8" from edge of platform. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

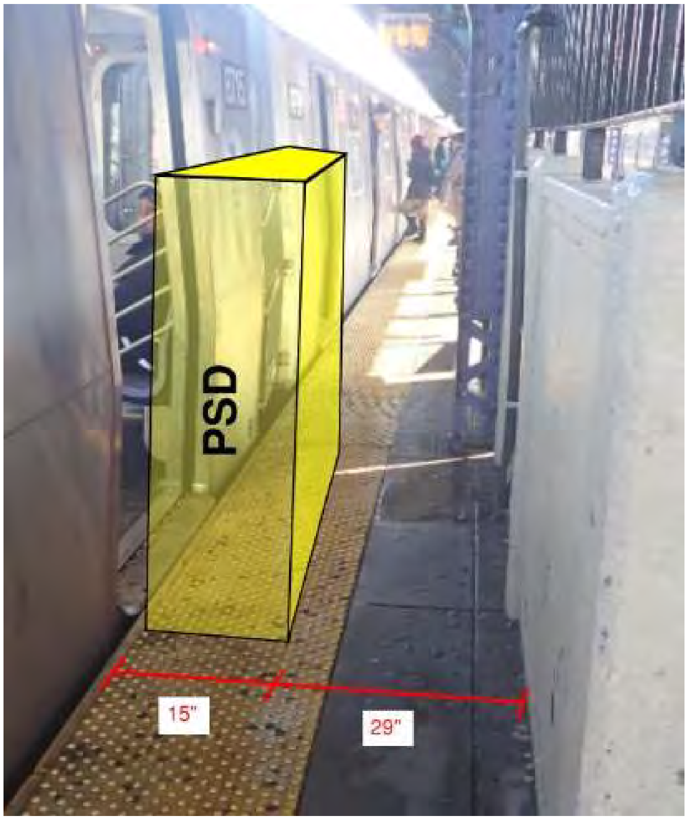

Figure 1 – *Area of ADA non-compliance*
Brighton Beach Station

Table of Contents

1.28 – MR 056 | Ocean Parkway Station

Summary: *Ocean Parkway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

The Ocean Parkway Station is an elevated station with two curved center / island platforms. The platform structures are cast-in-place concrete. The platforms are approximately 15'-0" in width. At stairway p-2, there is clearance of 3'-2" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement. The other three stairways are similar. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Area of ADA non-compliance*
Ocean Parkway Station

1.29 - MR-057 | West 8th Street Station

Summary: *West 8th Street Station (MR-57) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 17" (see figure 1).*

Description

West 8th Street Station is an elevated station with slightly curved side platforms that serve the 'F' and 'Q' trains. The lower platform level serves the 'F' line and the upper platform serves the 'Q' line (lower level is the subject of a separate report for the F service). The platform structure is cast-in-place concrete. The width of the platform varies from 5'-2" to 12'-10". At the escalator machine room, adjacent columns are 2'-8" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 17" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. Two of the stairways are similar. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

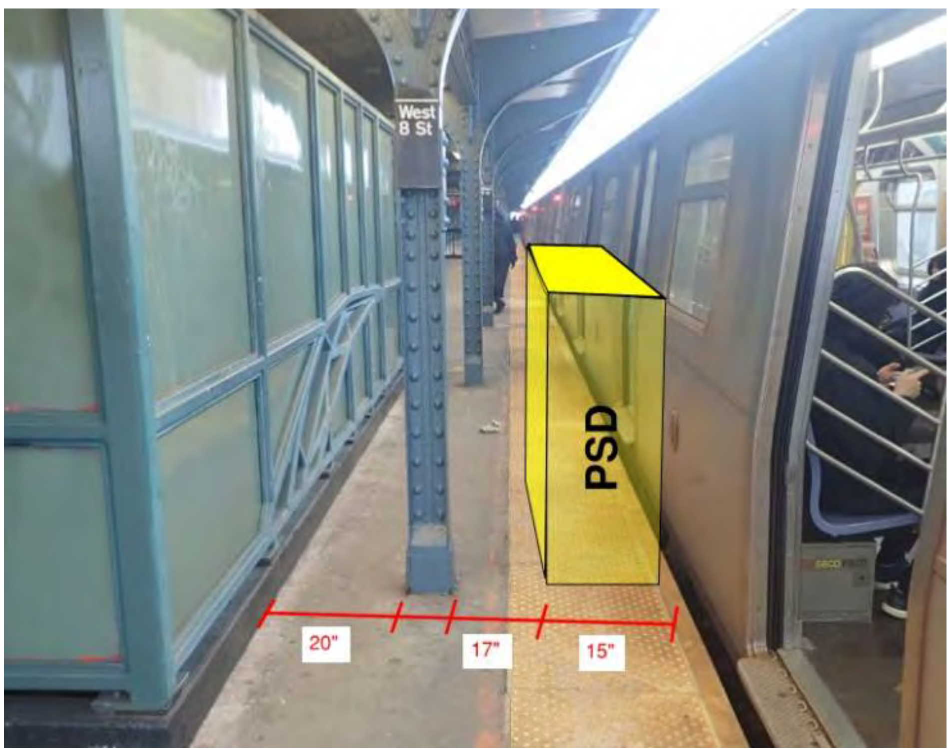

Figure 1 – Non-compliant ADA condition on the Manhattan-bound platform- West 8th St-NY Aquarium

1.30 – MR 058 Coney Island-Stillwell Avenue Station

Summary: *Coney Island-Stillwell Avenue Station is feasible for both APGs and PSDs. This station is the terminus station for the 'N', 'Q', 'D', and 'F' trains. Tracks 3 and 4 serve the Q line from a shared center / island platform. The canopy at this station is very tall, and there are no structural members directly above the platform edge. For the installation of a full height PSD system, structural members would have to be attached to existing beams that are approximately 12'-0" high and 5'-0" from the platform edge. One and a half train cars are not covered by a canopy. Therefore, a supplemental overhead structure would be needed in this part of the platform. Platform edge reconstruction will be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Coney Island-Stillwell Avenue Station is an elevated station with four center / island platforms. The 'Q' line platform is straight. The platform structure is made of cast-in-place concrete. There are two stairs and a centrally located ramp that provide access to the mezzanine level below. There are two rows of columns along the length of the platform. These columns are spaced approximately 20'-0" on center with column faces 6'-10" from the platform edge. The platform is 26'-0" in width. One and a half train cars are not covered by the canopy. A supplementary overhead structure would be required in these locations to accommodate a platform edge barrier. See figure 1 for an overall station plan.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the adjacent structure as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As indicated in the summary, there is no structure to mount to directly above the platform edge, requiring that some additional framing be constructed to hold the top of the PSDs. (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be in coordination with existing or replacement lighting. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated on the platform between columns at the center of the platform. The proposed room would measure approximately 16'-0" x 12'-0" (see figure 2). The other lines that are served at this station could use a similar room location on their respective platform (see figure 1)

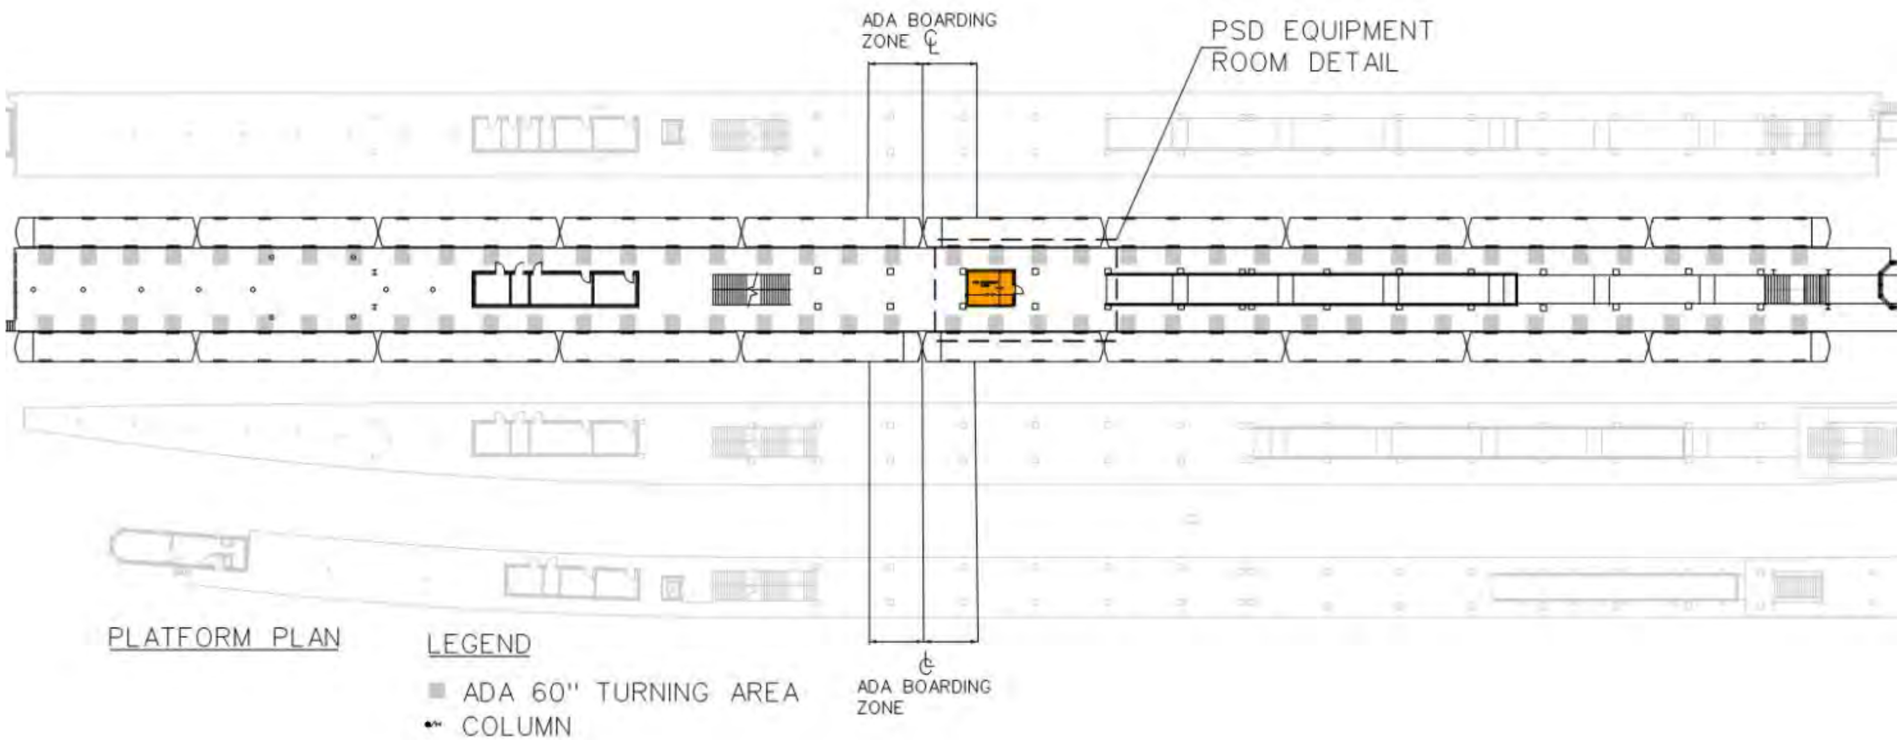

***Figure 1** – Station Plan*
Coney Island-Stillwell Avenue Station

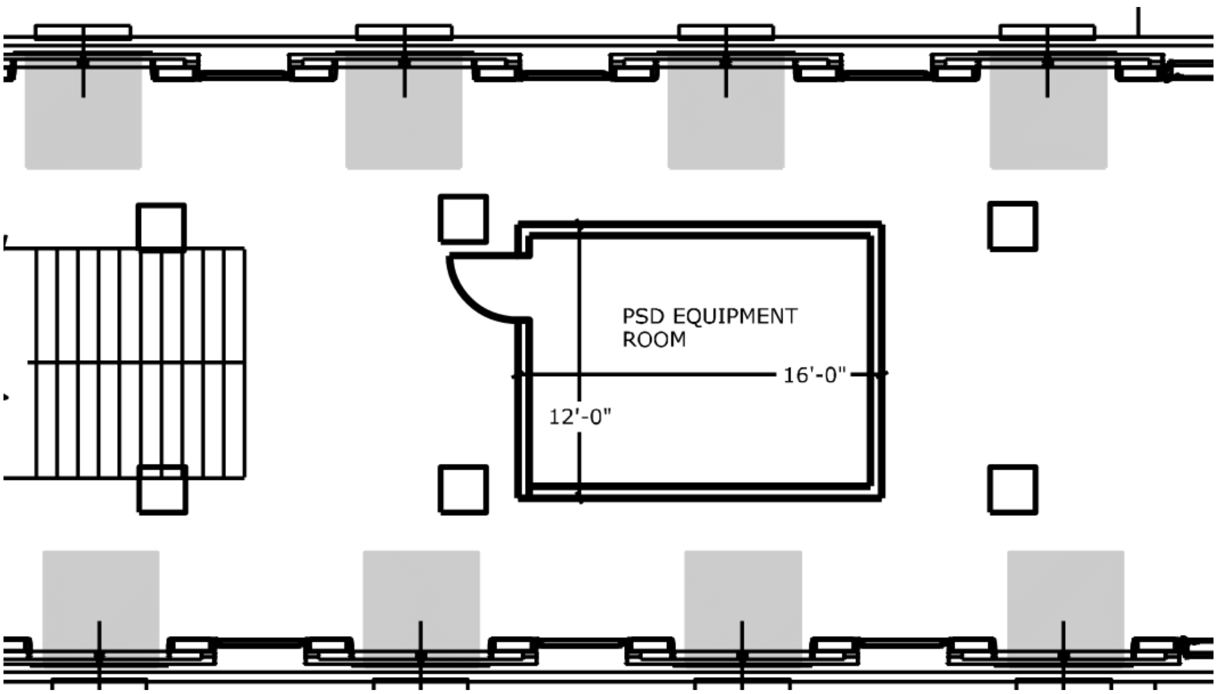

***Figure 2** – PSD Equipment Room Detail*
Coney Island-Stillwell Avenue Station

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform edge condition

The platform edges were reconstructed in 2004. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Platform obstructions within 5' of edge:

None.

Lighting:

Existing lighting: Linear fluorescent lights are mounted below the beams that run parallel to the platform. These beams are approximately 12'-0" high and 5'-0" from the edge of the platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

The existing Reserve electrical service is adequate for the installation of PSD/APG's. However, the Normal service is not adequate and therefore would not serve as a back-up system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 and Table 2 please see the Power Capacity Analysis for this station.

Station (Normal)
Power Capacity Analysis

Station Name	Coney Island Stillwell
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	552.0
Apparent Power (kVA)	690.0
Station Peak Demand Load, Max Current, (A)	1916.7
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	2549
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	0
Is Electrical Service Adequate?	**No**
Notes	This is for Normal service only. Station has (2) separate meter readings (not combined). Normal service has exceeded its service rating. **NO** additional load can be connected to this normal service.

Table 1. Power Capacity Analysis (Normal Service)

Station (Reserve)
Power Capacity Analysis

Station Name	Coney Island Stillwell
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	112.0
Apparent Power (kVA)	140.0
Station Peak Demand Load, Max Current, (A)	388.9
Maximum Amount of Doors	320.0
PSD Total Load Including All Miscellaneous Loads, (A)	632.6
Total Load (Station Peak + PSD), (A)	1022
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	179
Is Electrical Service Adequate?	Yes
Notes	This is for Reserve service only. This is based on assumption that each Service is separate. Reserve service has spare capacity. (Normal service has **NO** spare capacity)

Table 2. Power Capacity Analysis (Reserve Service)

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.0M to install APGs and $40.0M to install PSDs (See Appendix E).

***Figure 3** – Typical platform edge condition with line of potential supplementary framing*
Coney Island-Stillwell Avenue Station

Table of Contents

1.31 - MR-223 | Lexington Avenue-63rd Street Station

Summary: *Lexington Avenue-63rd Street Station (MR-223) is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Lexington Avenue- 63rd Street Station is a below-grade station with two straight center / island platforms (see figure 1). The platforms are stacked; the upper level provides Coney Island-bound service, while the lower level provides 96th Street-bound service. The platform structure is cast-in-place concrete. At the middle of both platforms there are six columns in two rows spaced 8'-0" apart with column faces 4'-6" from the edge of the platform. In addition to these columns, the lower level has a row of columns centered on the platform width spaced 15'-0" on center.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Due to the treatment of the ceilings at and beyond the platform edge, modification of metal panels may be necessary to create the supporting structure of a full height system. Additionally, relocation of police radio antenna may be required.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

This station will need two equipment rooms as there are four platform edges. For the two Q-line platform edges, one room can be located in the middle of the upper level platform between the existing columns. The proposed room dimension is 12'-0" x 16'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'Q' Line Stations
(Lexington Avenue-63rd Street Station)

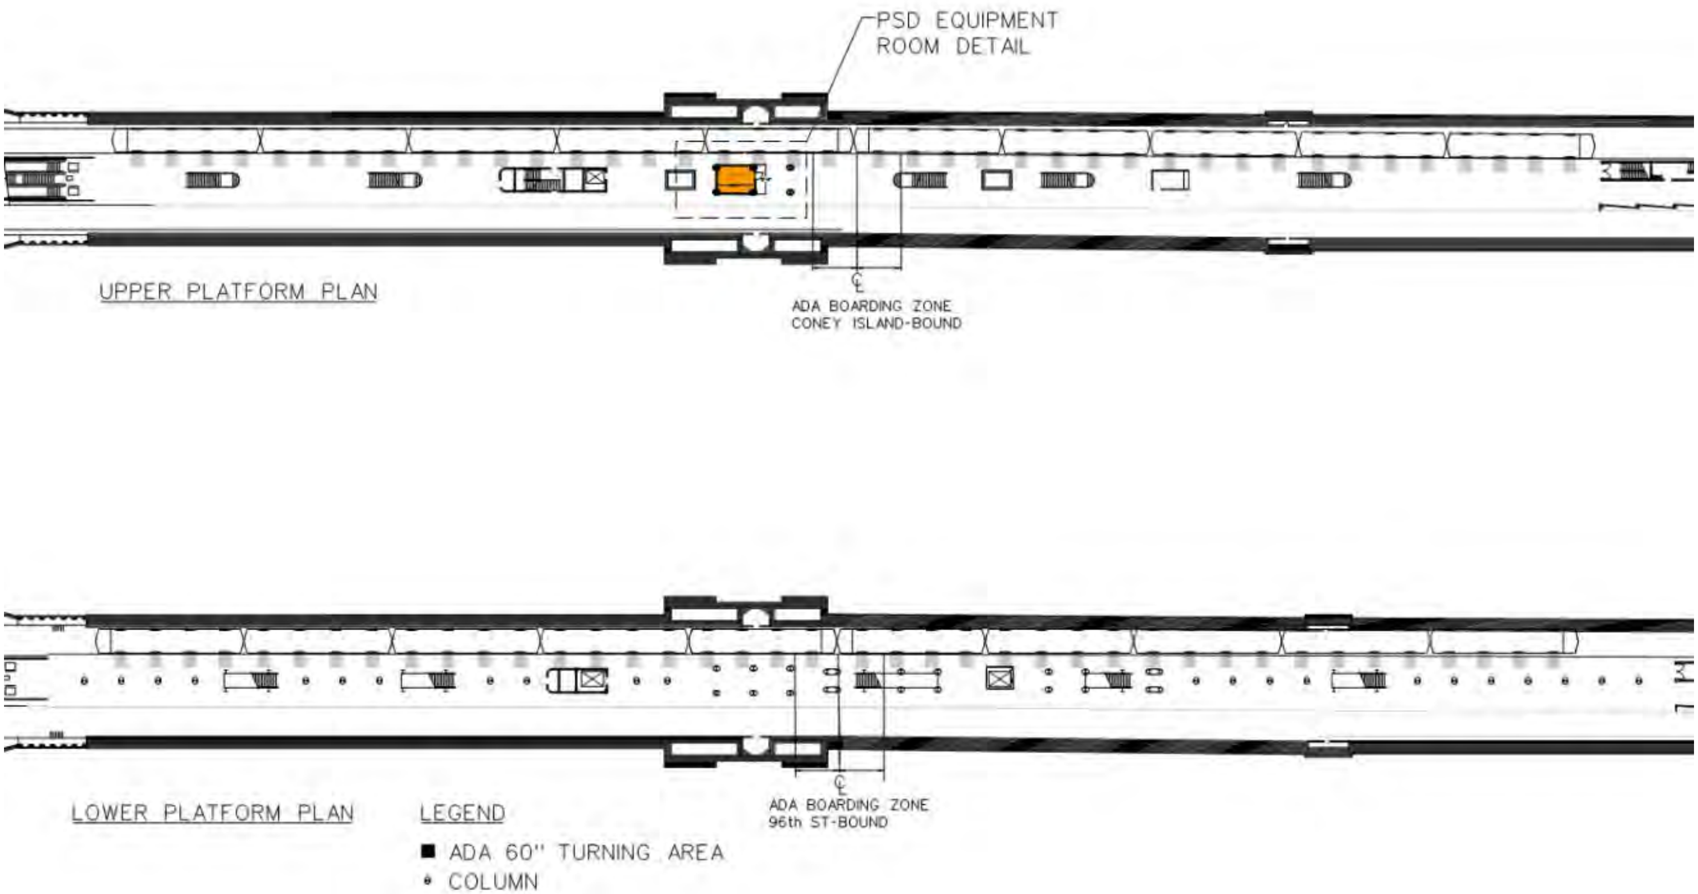

Figure 1 – Station Plan- Lexington Ave.-63rd St. Station

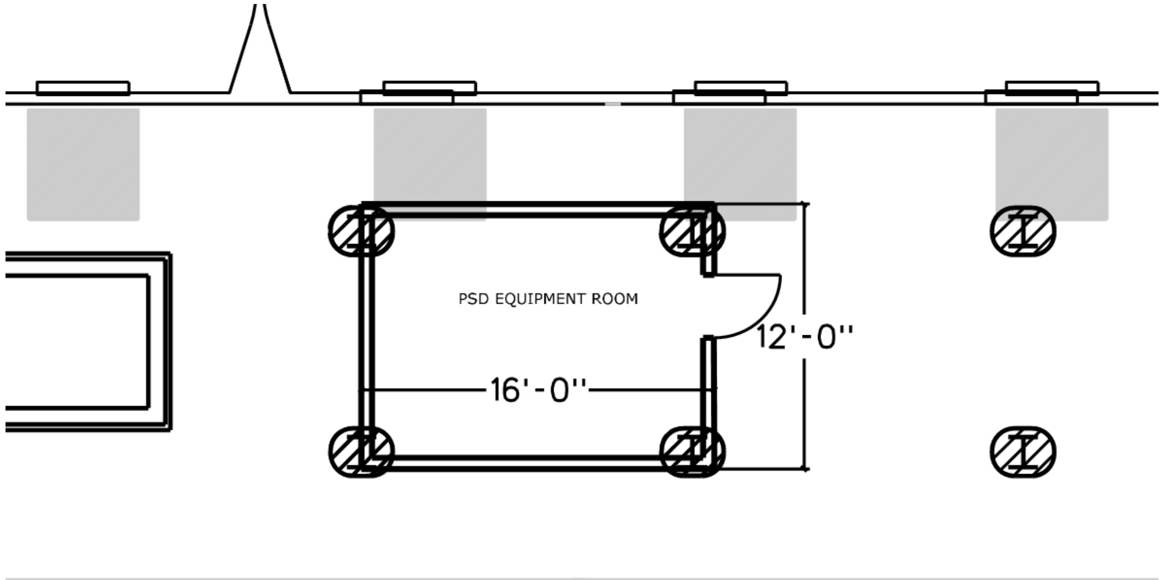

Figure 2 – PSD Equipment Room Detail – Lexington Ave.-63rd St. Station

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Platform obstructions within 5' of edge:

- Coney Island-bound: There are three columns that are 4'-6" away from the platform edge.
- 96th Street-bound: There are three columns that are 4'-6" away from the platform edge.

These obstructions do not present an impediment to the installation of PSDs.

Lighting:

Existing lighting: Lighting fixtures are fluorescent tubes recessed above removable ceiling panels, and encased fluorescent tubes installed approximately 60" away from the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.6M to install APGs and $39.2M to install PSDs (See Appendix E)

Figure 3 – Platform edge condition on the upper level (Coney Island-bound)- Lexington Ave.-63rd St. Station

Table of Contents

Figure 4 –Platform edge condition on the lower level (96th Street-bound)- Lexington Ave.-63rd St. Station

Table of Contents

1.32 – MR 475 | 96th Street

Summary: *96th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

96th Street Station is a below-grade station with one center / island platform (**see Figure 1)**. This is a newly constructed station completed in 2016.The platform structure is cast-in-place concrete. There are no columns throughout the platform. The platform width is 29'-3" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Due to the treatment of the ceilings at and beyond the platform edge, modification of metal panels may be necessary to create the supporting structure of a full height system. Additionally, relocation of police radio antenna may be required.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were constructed within the past five years. From our limited visual inspection and our knowledge of structural details of the platform construction, structural work would at a minimum be required for the installation of an APG system.

It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $39.1M to install PSDs (See Appendix E)

Table of Contents

1.34 – MR 477 | 72nd Street

Summary: *72nd Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

72nd Street Station is a below-grade station with one center / island platform (**see Figure 1)**. This is a newly constructed station completed in 2016. The platform structure is cast-in-place concrete. There are no columns on the platform. The platform width is 27'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Due to the treatment of the ceilings at and beyond the platform edge, modification of metal panels may be necessary to create the supporting structure of a full height system. Additionally, relocation of police radio antenna may be required.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were constructed within the past five years. From our limited visual inspection and our knowledge of structural details of the platform construction, structural work would at a minimum be required for the installation of an APG system.

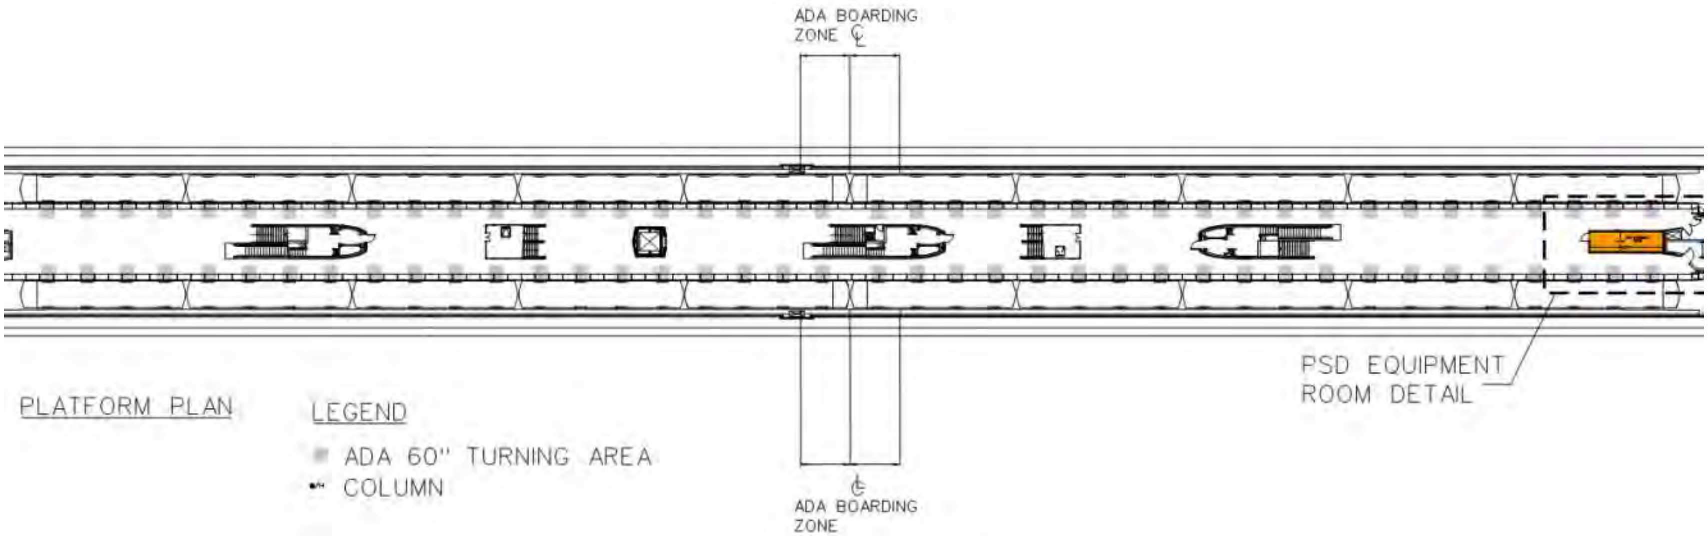

Figure 1 – Overall Station Plan
72nd Street Station

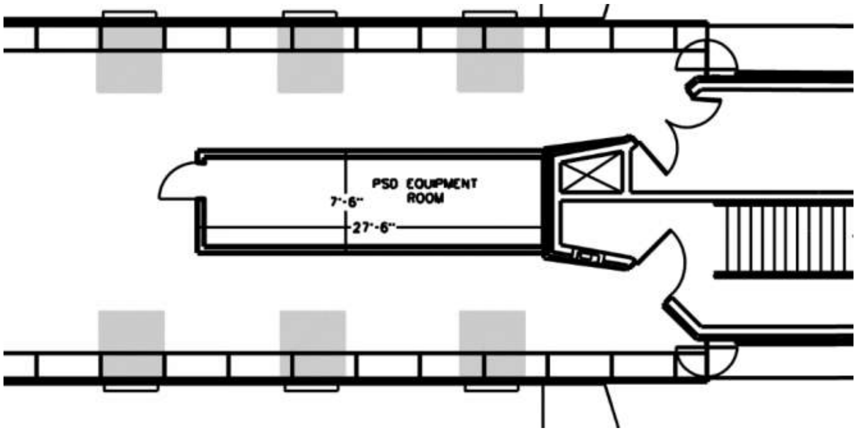

***Figure 2** – PSD Equipment Room Detail*
72nd Street Station

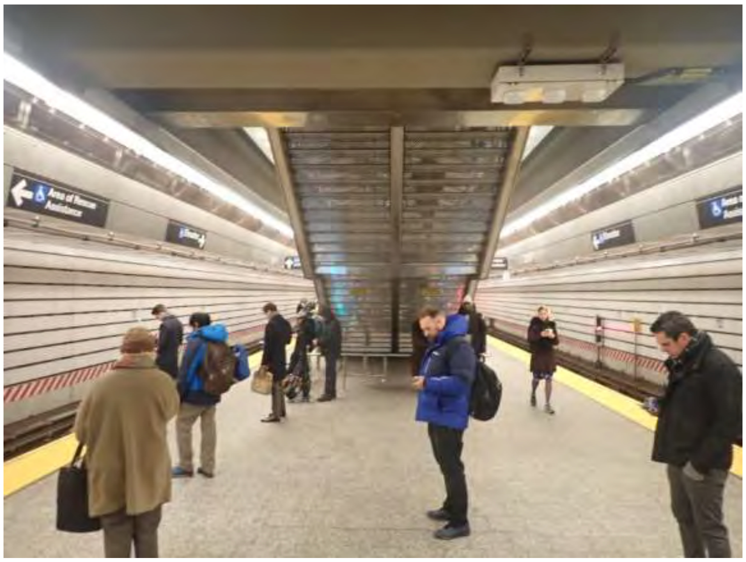

***Figure 3** – Typical platform view*
72nd Street Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout the platform there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $39.3M to install PSDs (See Appendix E).

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.

k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.

l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	Comments
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

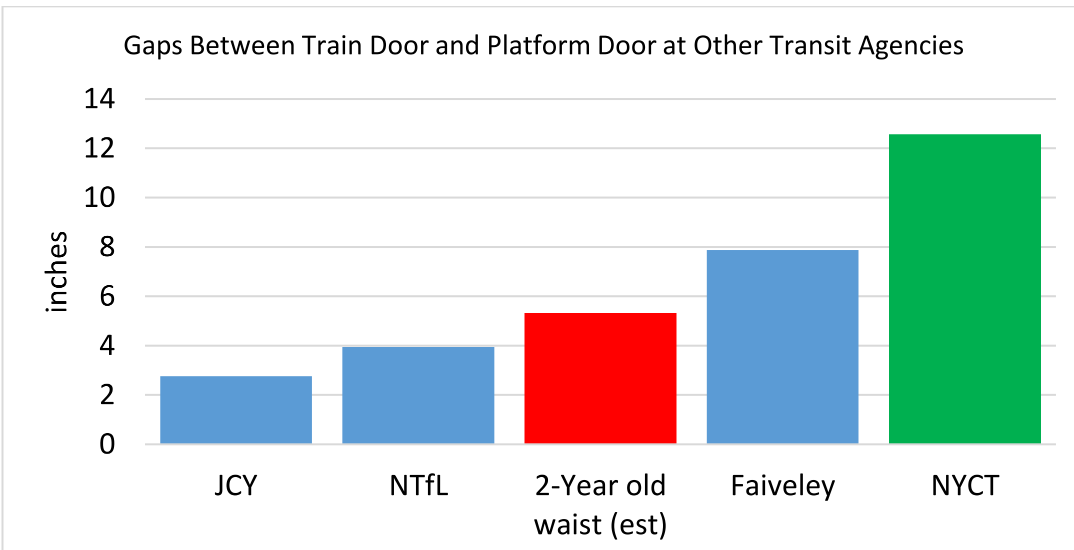

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

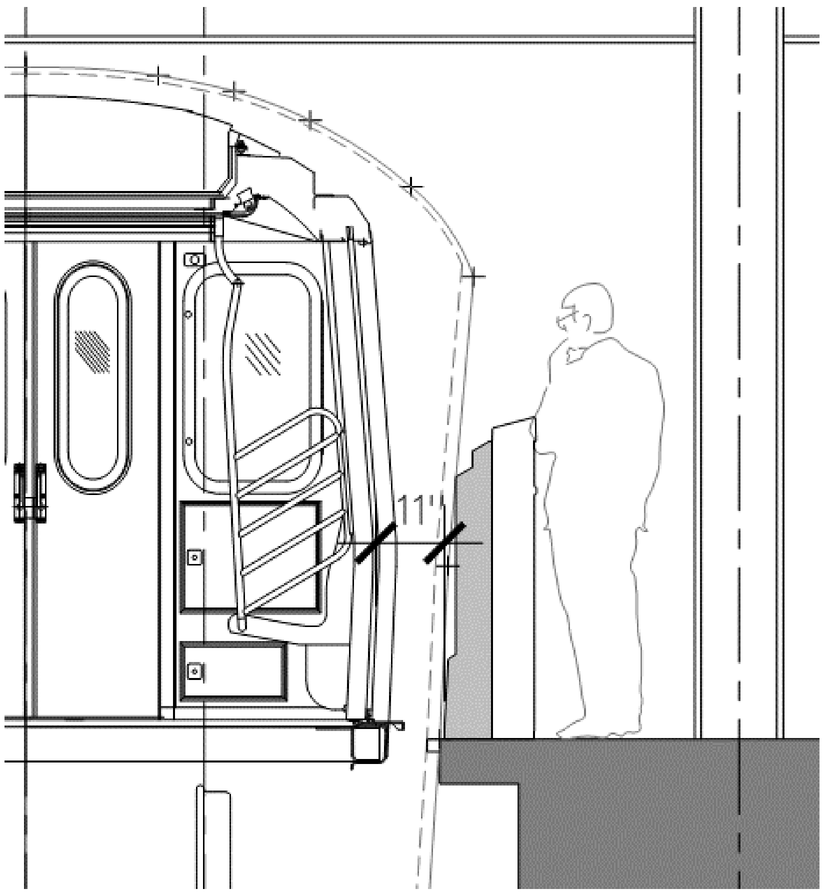

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

304 Turning Space

304.1 General. Turning space shall comply with 304.

304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.

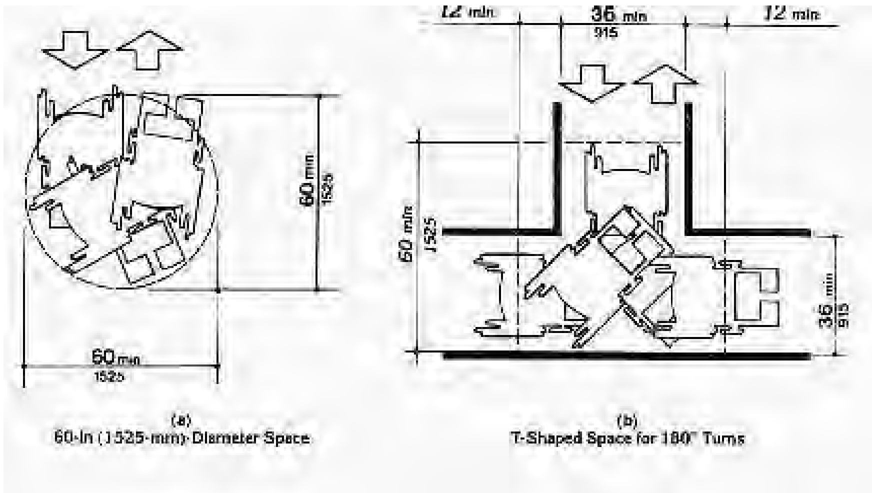
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

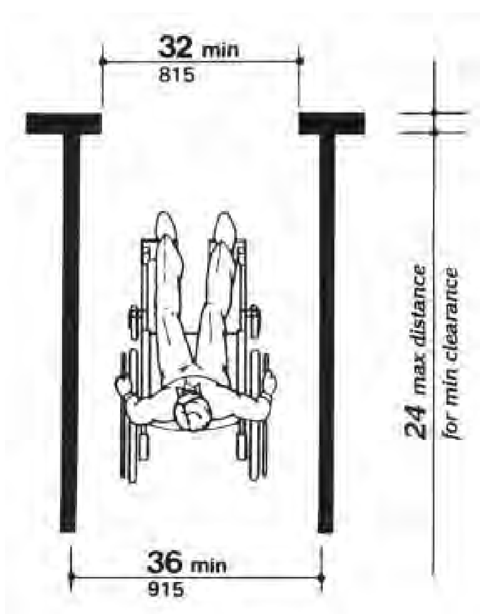


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

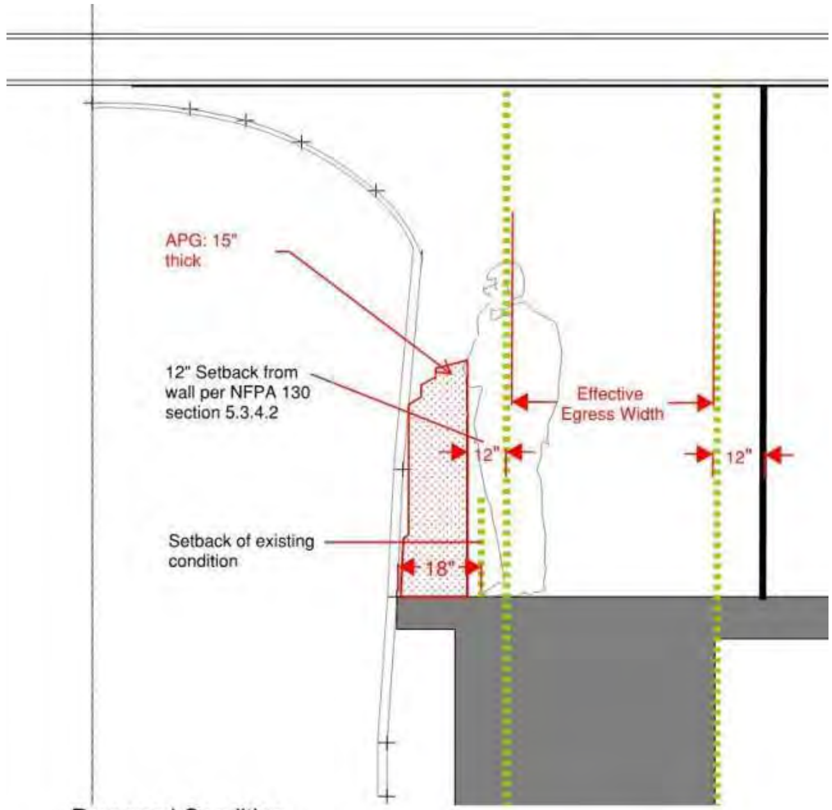
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Table of Contents Appendix Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

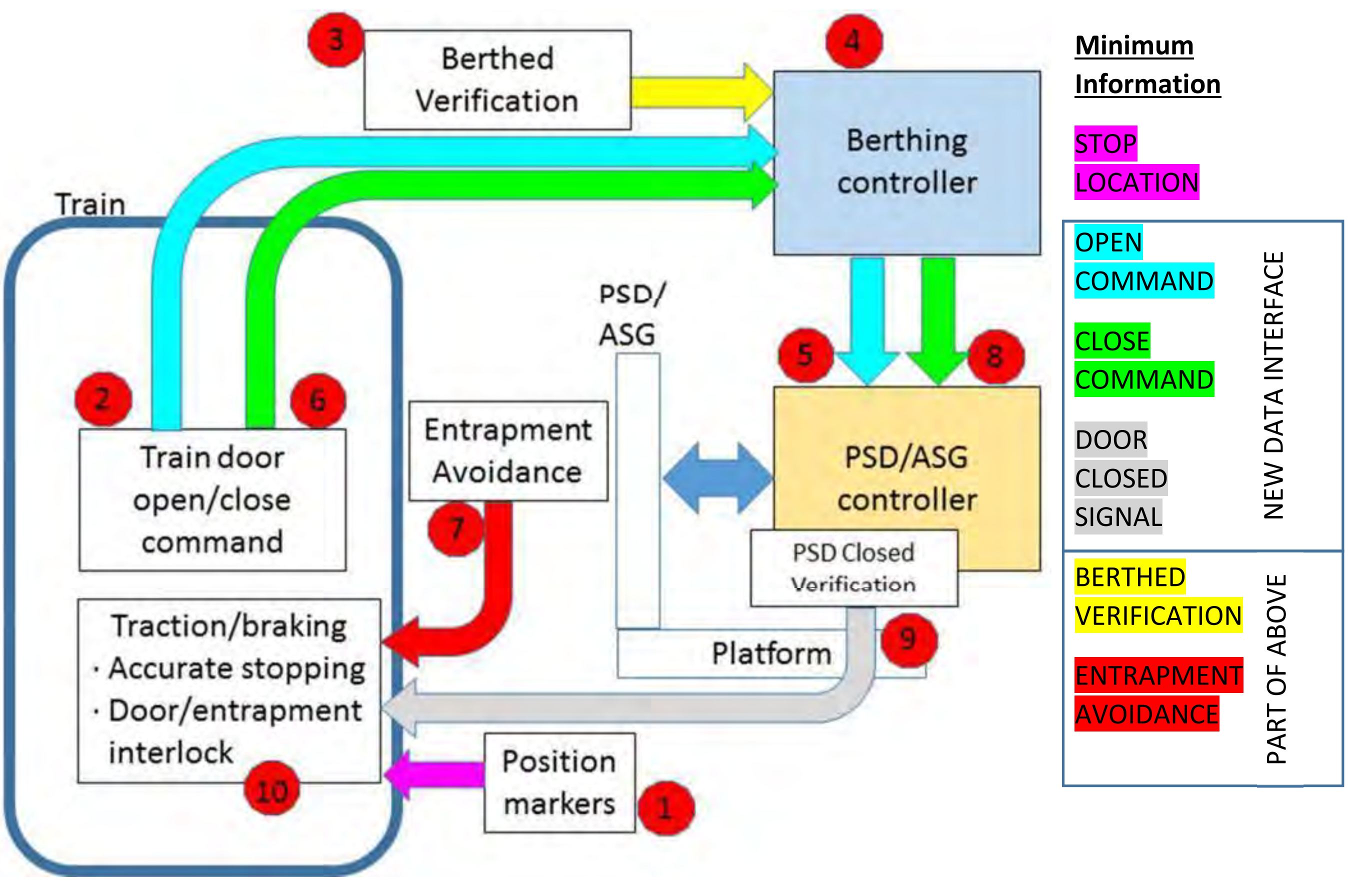
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

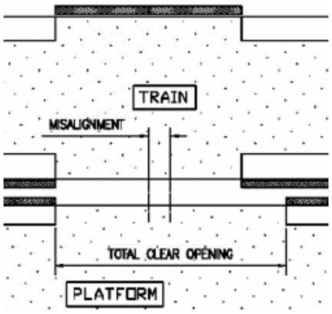
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

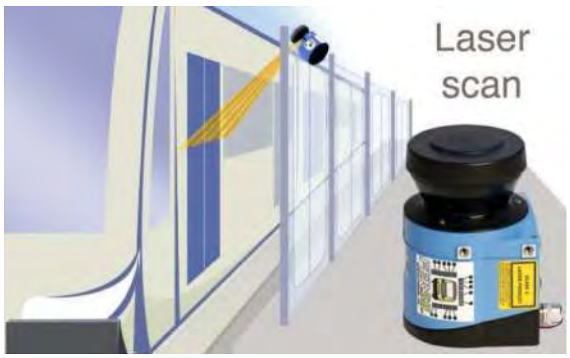
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

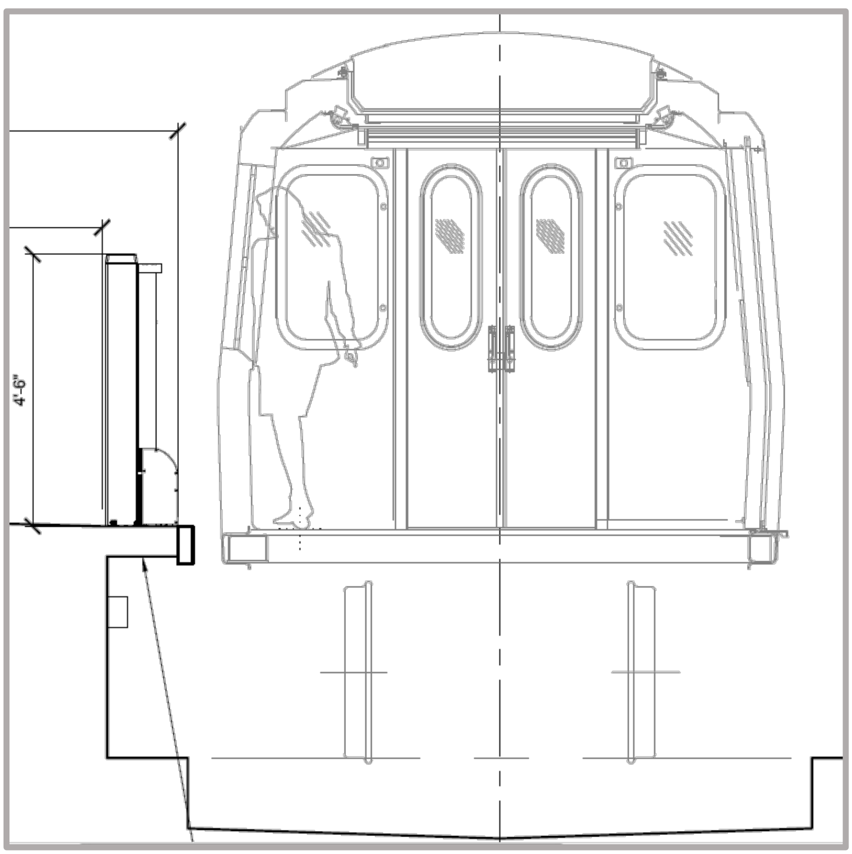


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

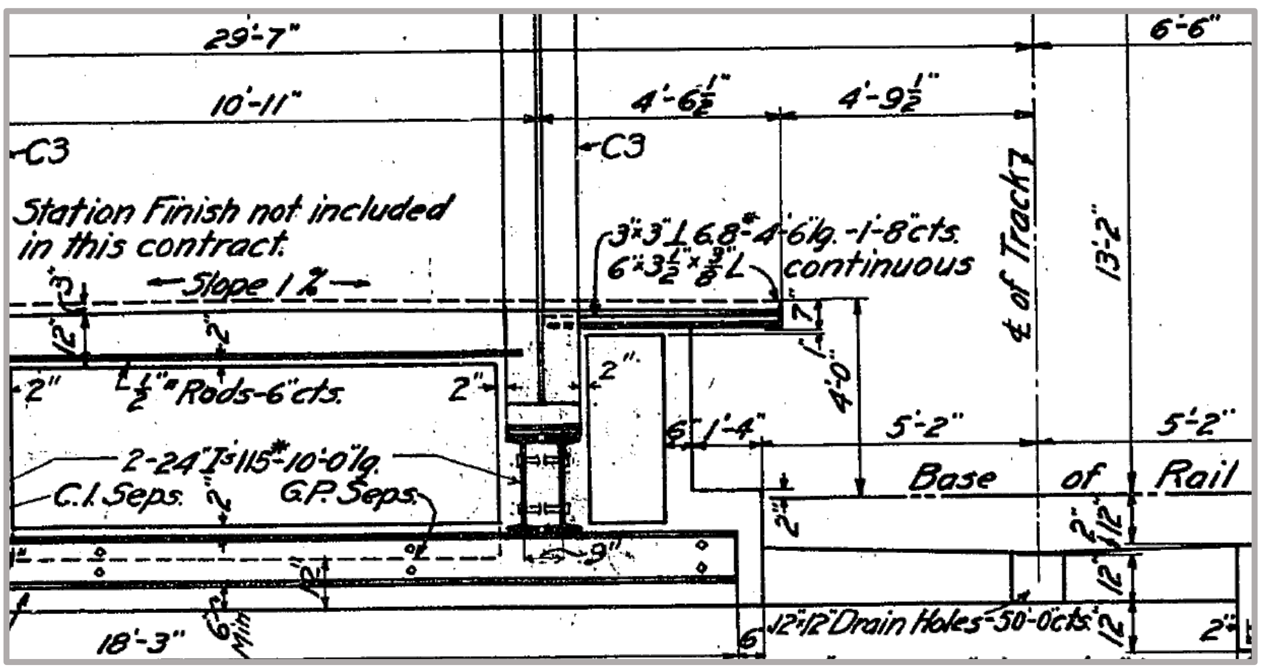

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

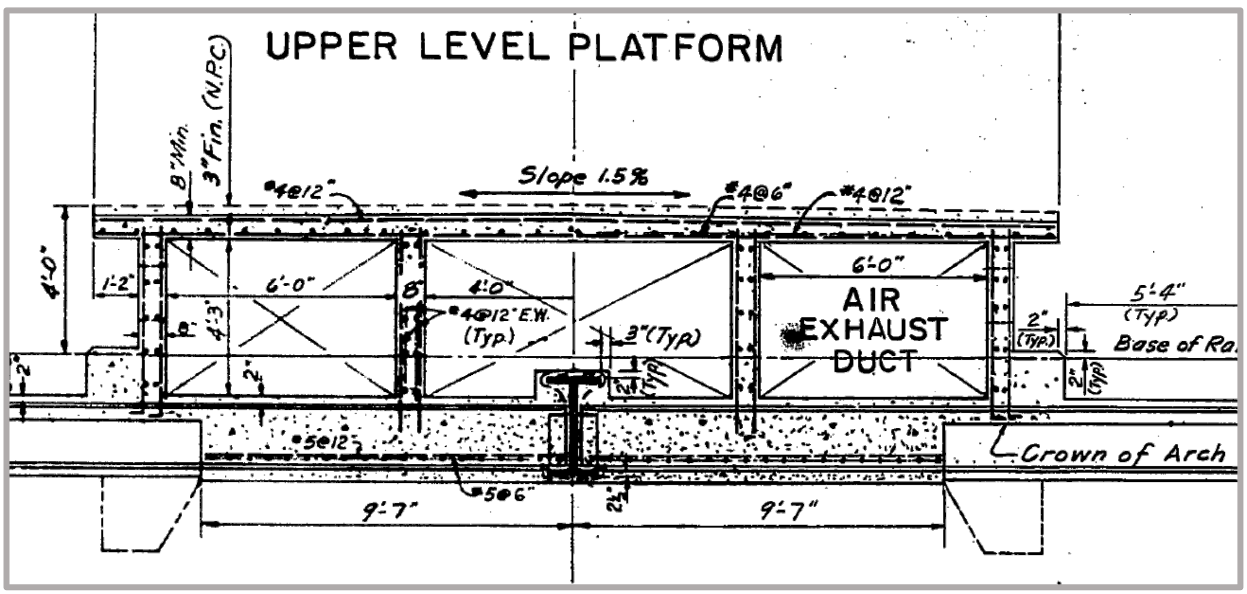

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

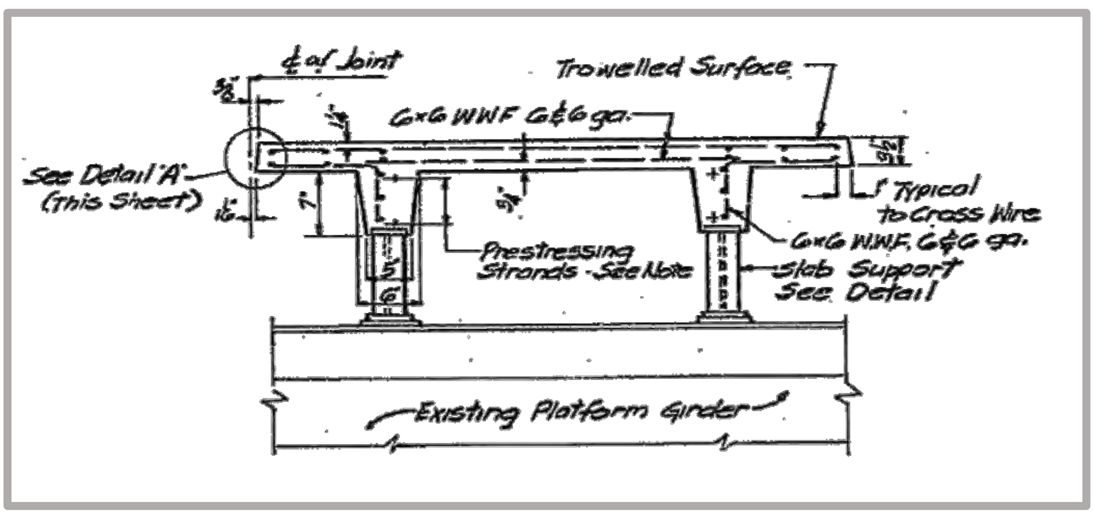

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

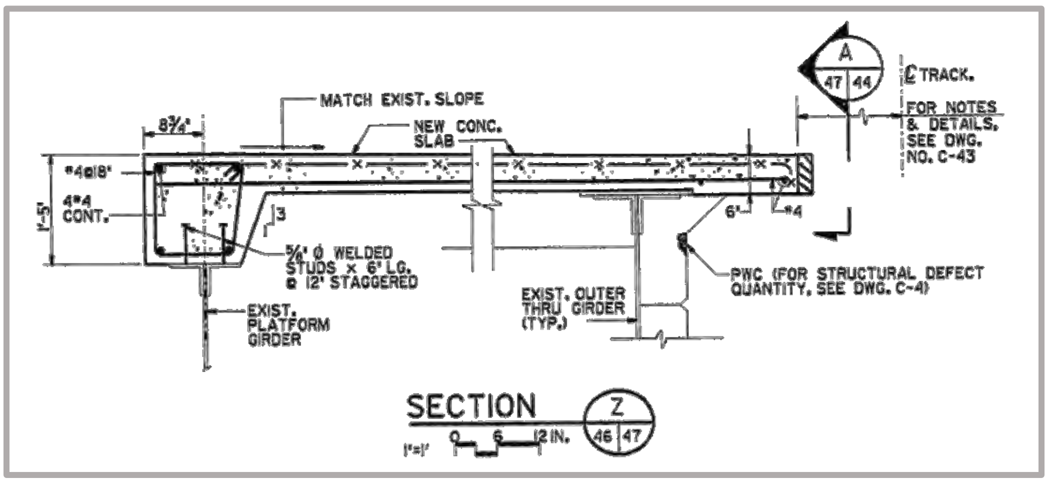

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2’-9”), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

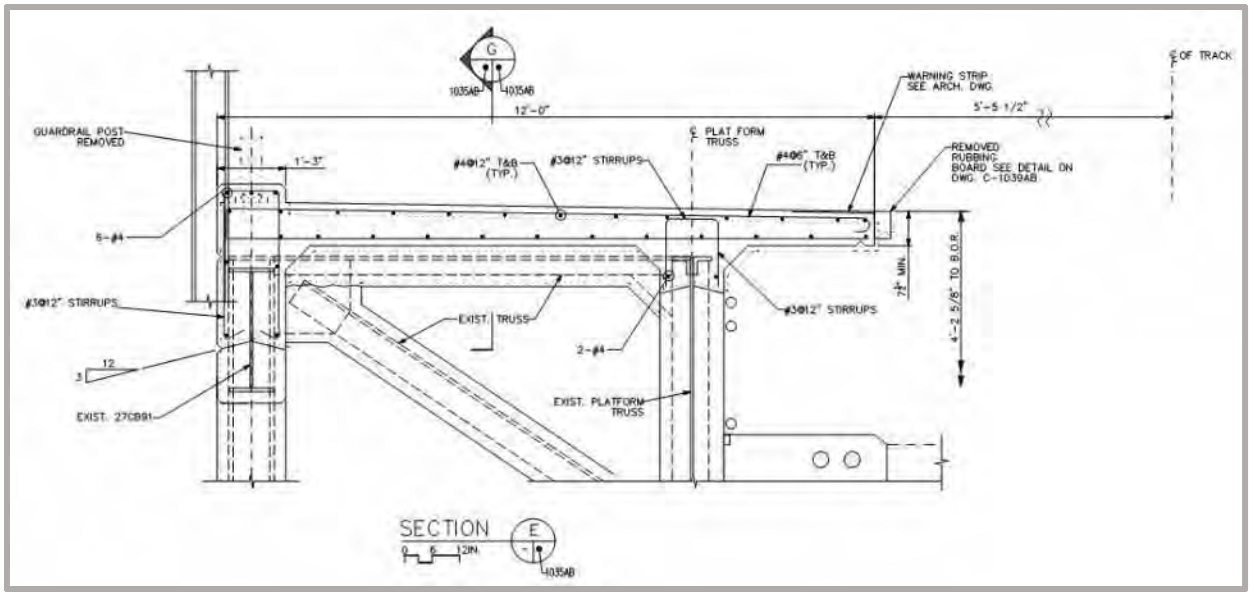

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

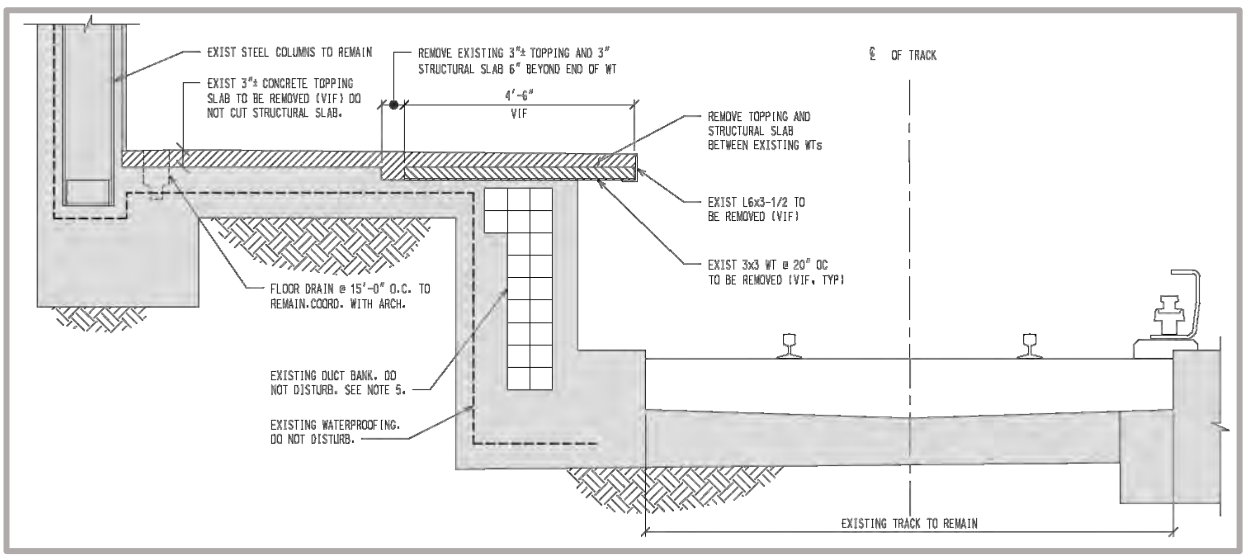

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

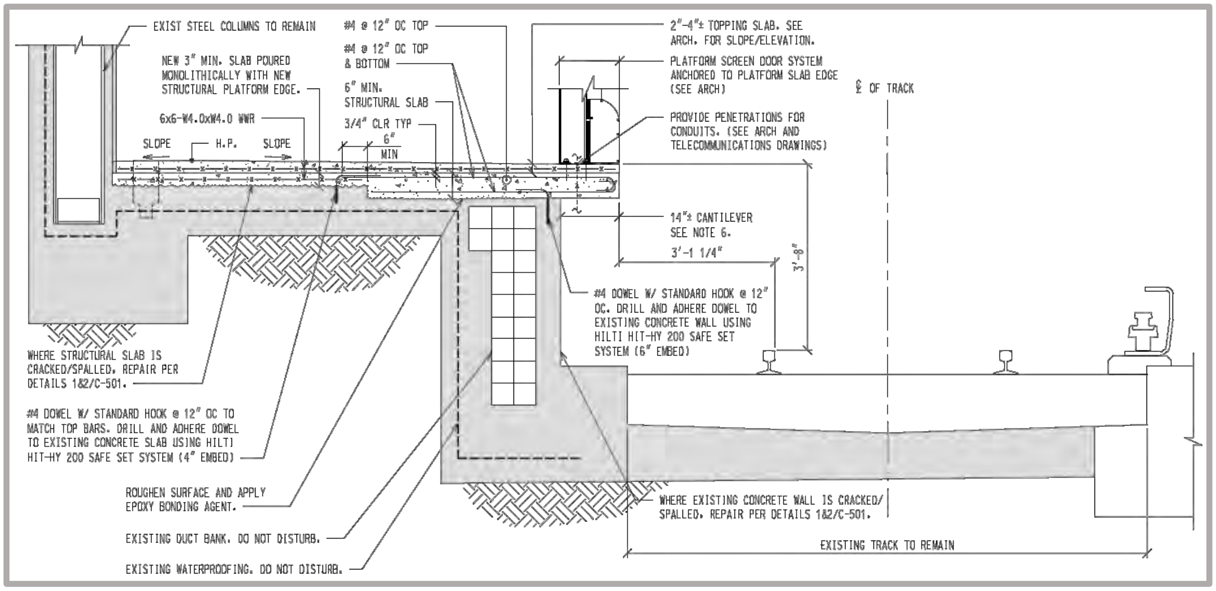

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

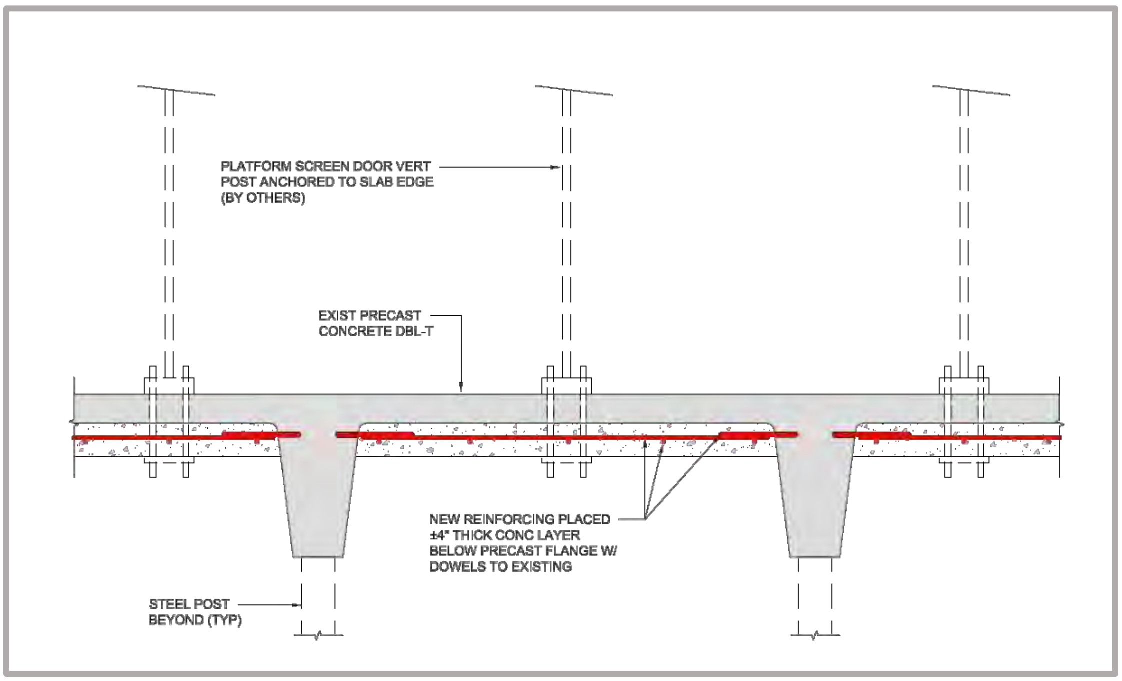

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

	Technical Assistance [4 Hrs per Month]	60	$ 920 per month	$ 55,200		
	As Needed On-Site Support [1 Day per Month]	480	$ 230 per Hour	$ 110,400		
	Software / Firmware Support	5	$ 3,750 per Year	$ 18,750	$ 755,850	$ 755,850
5	Optional Maintenance for years 11-15	Year 11-15				
	Repair and Replacement of Defective Hardware	60	$ 12,700 per month	$ 762,000		
	Technical Assistance [5 Hrs per Month]	60	$ 1,200 per month	$ 72,000		
	As Needed On-Site Support [1.5 Days per Month]	720	$ 240 per Hour	$ 172,800		
	Software / Firmware Support	5	$ 4,000 per Year	$ 20,000	$ 1,026,800	$ 1,026,800
6	Optional Maintenance for years 16-20	Year 16-20				
	Repair and Replacement of Defective Hardware	60	$ 15,875 per month	$ 952,500		
	Technical Assistance [6 Hrs per Month]	60	$ 1,500 per month	$ 90,000		
	As Needed On-Site Support [2 Days per Month]	960	$ 250 per Hour	$ 240,000		
	Software / Firmware Support	5	$ 4,500 per Year	$ 22,500	$ 1,305,000	$ 1,305,000
	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 2) [DEFAULT OPTION AS PER RFP DOCUMENTATION]		TOTAL:	$ 6,078,826	$ 6,078,826	$ 7,619,663
	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 1)		TOTAL:	$ 7,619,663		

7	Labor Bill Rate (per hour)	Year 1	$ 238 per hour *	
	Task Orders (Rate in Effect 24/7/365)	Year 2	$ 248 per hour *	
		Year 3	$ 257 per hour *	
	Optional :	Year 4	$ 268 per hour *	
	Optional :	Year 5	$ 278 per hour *	

Note: Labor rate is deemed to include all relevant tax and insurance, medical, pension, vacation fund, etc., travel time to and from project site and night/shift/weekend/holiday work i.e. 24/7 Rate

* Labor rates include Contractor's Overhead & Profit and Insurance (Refer Annual Maintenance Cost Breakdown) and are escalated at 4% per annum

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

MTA/NYCT

June 12, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

MTA/NYCT

June 12, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

12-Jun-19

STATION : 49TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	703	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	703	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,406**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,406	LF	7	9,842
14	Remove 5' wide section of 3" deep structural slab to platform edge	7,030	SF	12	84,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	142	CY	2,500	355,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,408	EA	25	35,200
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,408	EA	25	35,200
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,406	LF	95	133,570
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,406	LF	15	21,090
26	Remove existing platform tiles	1,406	LF	12	16,872
27	Sawcut existing topping concrete at perimeter of removal area	1,406	LF	5	7,030
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,436	SF	8	67,488
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	320	SF	8	2,560
30	New Work				
31	New concrete topping to match existing	1,406	SF	15	21,090

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

12-Jun-19

STATION : AVENUE J

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	624	LF		
5	LENGTH OF THE PLATFORM EDGE =	611	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,234**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,234	LF	7	8,640
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,171	SF	12	74,055
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,236	EA	25	30,906
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,236	EA	25	30,906
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,234	LF	95	117,254
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,234	LF	15	18,514
26	Remove existing platform tiles	1,234	LF	12	14,811
27	Sawcut existing topping concrete at perimeter of removal area	1,234	LF	5	6,171
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,406	SF	8	59,244
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Platform width i.e. 8'-0" wide	160	SF	8	1,280
30	New Work				
31	New concrete topping to match existing	1,234	SF	15	18,514

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

12-Jun-19

STATION : CONEY ISLAND

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	615	LF		
5	LENGTH OF THE PLATFORM EDGE =	616	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,231**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,231	LF	7	8,617
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,155	SF	12	73,860
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,233	EA	25	30,825
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,233	EA	25	30,825
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,231	LF	95	116,945
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,231	LF	15	18,465
26	Remove existing platform tiles	1,231	LF	12	14,772
27	Sawcut existing topping concrete at perimeter of removal area	1,231	LF	5	6,155
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,386	SF	8	59,088
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Platform width i.e. 27'-6" wide strip	620	SF	8	4,960
30	New Work				
31	New concrete topping to match existing	1,231	SF	15	18,465

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

12-Jun-19

STATION : 96TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE=	627	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE =	627	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,254**	**LF**		
7	NUMBER OF TRAIN CARS ON W TRAIN TRACK =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,254	LF	7	8,778
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,270	SF	12	75,240
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	126	CY	2,500	315,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,256	EA	25	31,400
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,256	EA	25	31,400

150	Fixed Panels including framing and support; 4'-6" High	(2,358)	SF	750	(1,768,500)
151	Spare Parts - Approx. 10% of Material Cost	(1)	LS	232,770	(232,770)
152	Platform Edge Reconstruction work	(1)	LS	510,640	(510,640)
153	Remove allowance for cast in sleeves for LV & HV power	(328)	EA	110	(36,080)
154	Conduit running under Platform Edge	(1,254)	LF	30	(37,620)
155					
156	Allow loss of production to work at night say 50%	1	LS	979,027	979,027
157					
158	PREMIUM ASSOCIATED WITH PSD's				$ 4,242,450

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Q - Line Stations

12-Jun-19

STATION : 86TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	623	LF		
5	LENGTH OF THE PLATFORM EDGE [ASTORIA BOUND] =	623	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,246**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,246	LF	7	8,722
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,230	SF	12	74,760
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	125	CY	2,500	312,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,248	EA	25	31,200
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,248	EA	25	31,200
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,246	LF	95	118,370
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,246	LF	15	18,690
26	Remove existing platform tiles	1,246	LF	12	14,952
27	Sawcut existing topping concrete at perimeter of removal area	1,246	LF	5	6,230
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,476	SF	8	59,808
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Platform width i.e. 28'-3" wide strip	650	SF	8	5,200
30	New Work				
31	New concrete topping to match existing	1,246	SF	15	18,690

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'R' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017216

SUBMITTAL DATE: June 24, 2019

STV 100 Years

Table of Contents

Appendices

Appendix A: Tier 2-3 Technology assessment

Appendix B: Structural Feasibility Report

Appendix C: Emergency Egress Width Analysis

Appendix D: maintenance Cost Estimate

Appendix E: Rough Order of Magnitude Costs

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 45 newly evaluated stations, 42 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32" pinch width, it is declared infeasible. This requirement dictates that if a column or any obstruction measuring less than or equal to 24" in the direction of circulation is present, it may not constrain the circulation path to less than 32".
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Car door misalignment (part of Tier 1 selection process): Presently (2018) the NYCT system features three car geometries on the A Division and three car geometries on the B Division. With few exceptions, these cars are freely mixed between lines. The spacing of doors on these differing cars is significantly misaligned, making the installation of platform doors infeasible. Looking to the future, NYCT plans to procure new rolling stock with identical or nearly identical door spacing. The current procurement schedule indicates the purchase of these geometrically compatible cars by 2032. Therefore, our assessment of feasibility is based on the year 2032.

  However, the R line service and several overlapping services on the B Division will remain incompatible even after 2032. The R is a ten-car train, whereas the M line, which shares its route, is an eight-car train. The newer trains are assembled in two consists, with a driver / conductor cabin at the front and back of each consist. Due to the cabin, the spacing of doors on the first and last car differs from the door spacing of the other cars of the train. Therefore, there will inevitably be a mismatching of doors as these two differing train types berth at a certain station platform. The M train cannot be extended to a ten-car length because all the station stops in Brooklyn feature station platforms of an eight-car length. Please see the diagrams in Figure 1 below.

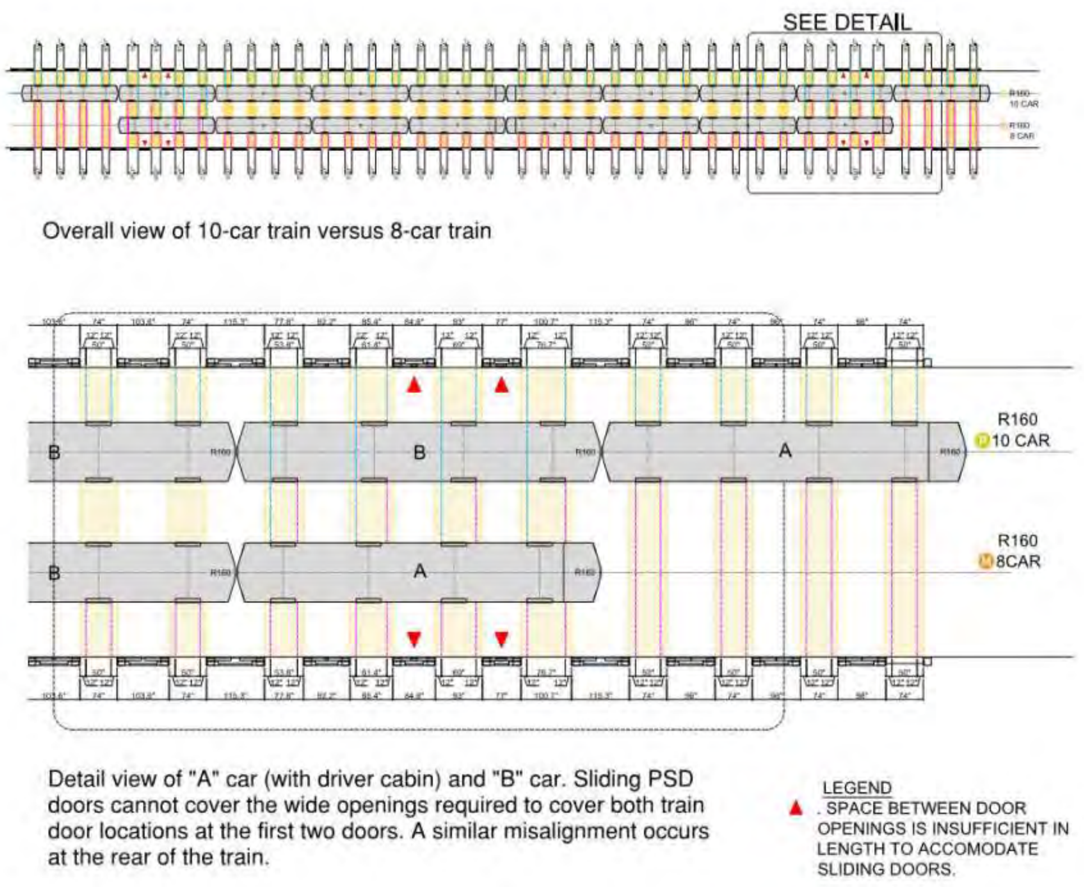

***Figure 1** – Ten-car vs. eight-car train Comparison of door geometry*

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at the R line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 6% of the 'R' Line stations. Total implementation cost would be $96.1M for APGs and $123.4M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 3 feasible stations, the aggregate annual maintenance cost would be $2.8M.

1.0 Station Assessment

1.01 – MR 007 | Lexington Avenue / 59th Street Station

Summary: *Lexington Avenue / 59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all obstructions as the remaining width would be 30" (see figure 1).*

Description

Lexington Avenue / 59th Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 20'-0" throughout. Columns are spaced 15' on center with column faces 4'-0" away from the platform edges. The walls at the end of platform are 45" from the platform edge. The implementation of a platform edge barrier would reduce this width to 30" or less* which would not allow for ADA compliant wheelchair movement. Please see **figure 1** for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Lexington 59th Street Station

1.02 – MR 008 | Fifth Avenue / 59th Street Station

Summary: *Fifth Avenue / 59th Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at the center of each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Fifth Avenue / 59th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound platform width is approximately 11'-10" throughout. The northbound platform width is approximately 11'-6" throughout. At the center of each platform there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs. **(see Figure 3)**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located at the west mezzanine flush to the wall (see **Figure 1, Figure 2**). The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in 1995. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required only for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'R' Line Stations
(Fifth Avenue / 59th Street Station)

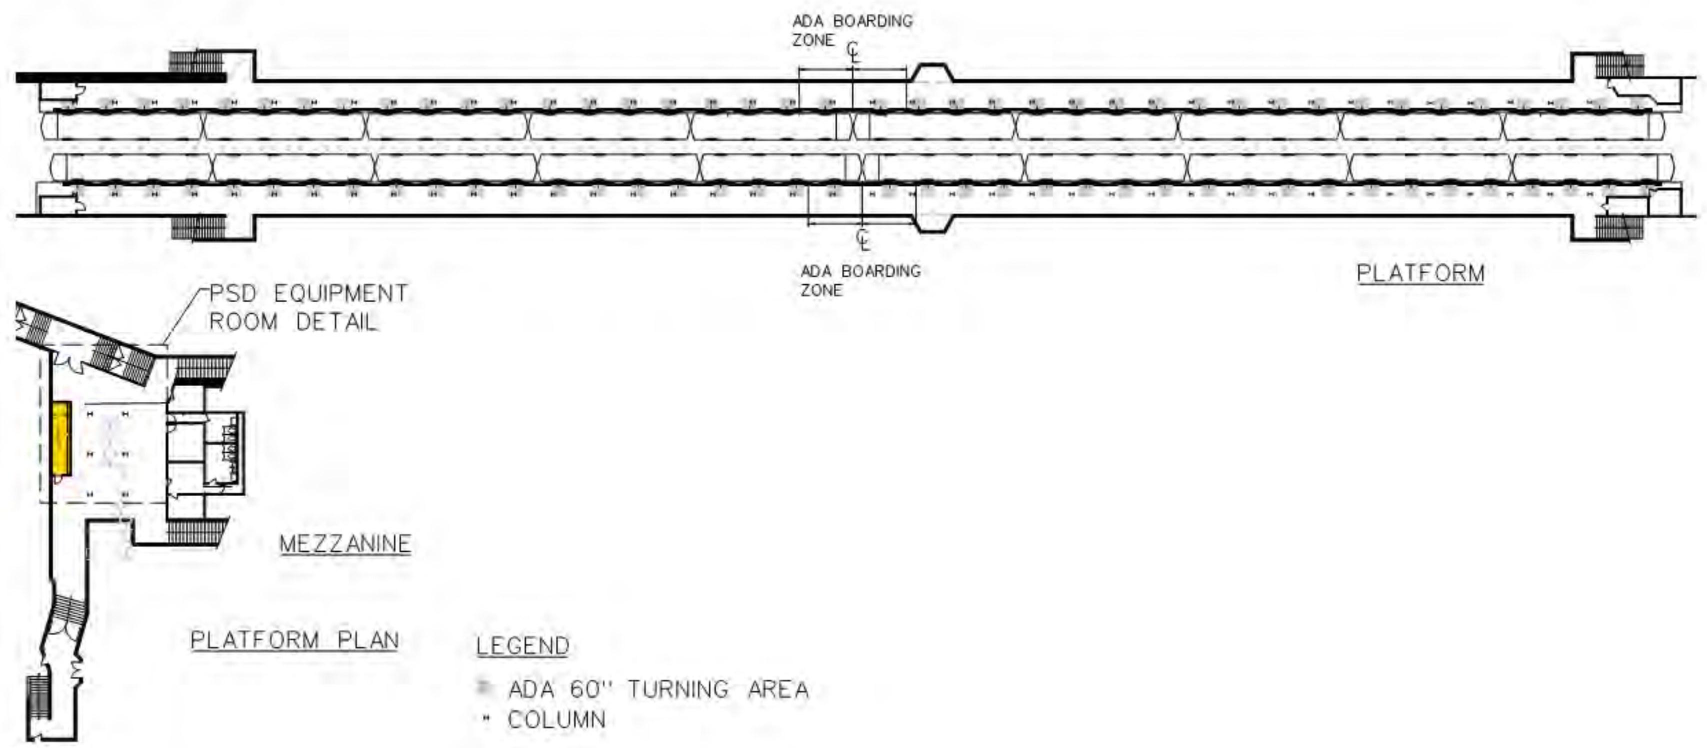

Figure 1 – Overall Station Plan
Fifth Avenue Station

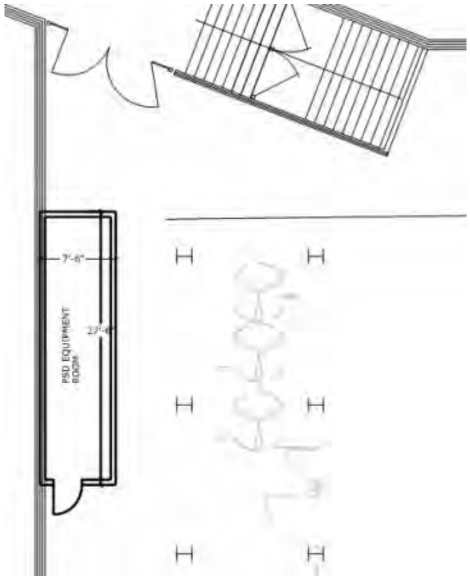

***Figure 2** – PSD Equipment Room Detail*
Fifth Avenue Station

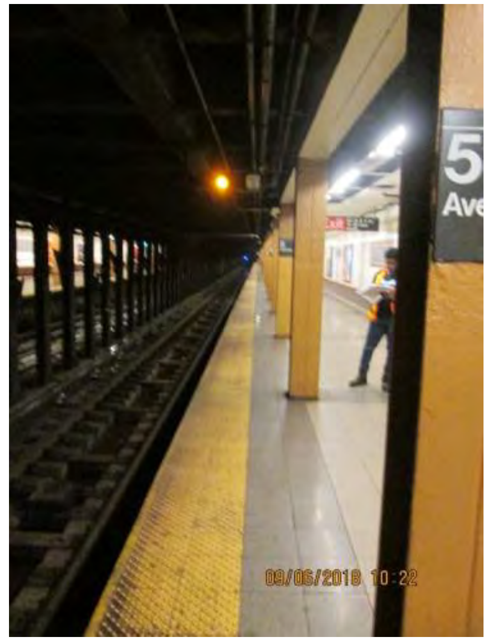

***Figure 3** – Signal above platform edge*
Fifth Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $31.2M to install APGs and $40.0M to install PSDs (See Appendix E)

***Figure 4** – Typical Platform View*
Fifth Avenue Station

1.03 – MR 009 | 57th Street 7th Avenue Station

***Summary:** 57th Street 7th Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the center stairs as the remaining width would be 27" (see figure 1).*

Description

The 57th Street Station is an underground station consisting of two center / island platforms. The platforms are approximately 19'-8" wide. The platforms are straight with two rows of columns at 42" from the edge of the platform. At four staircases columns flank the stair. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA dimension*
57th Street Station

Table of Contents

1.04 – MR 010 | 49th Street Station

Summary: *49th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). The existing power supply is adequate.*

Description

The 49th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns on the platforms. The platform width varies from approximately 7'-0" to 14'-8". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located as a split room, with one at the south control area of the southbound, and one located at the north control area of the southbound. (see **Figure 1, Figure 2**). The proposed room dimensions are 16'-0" x 7'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last twenty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

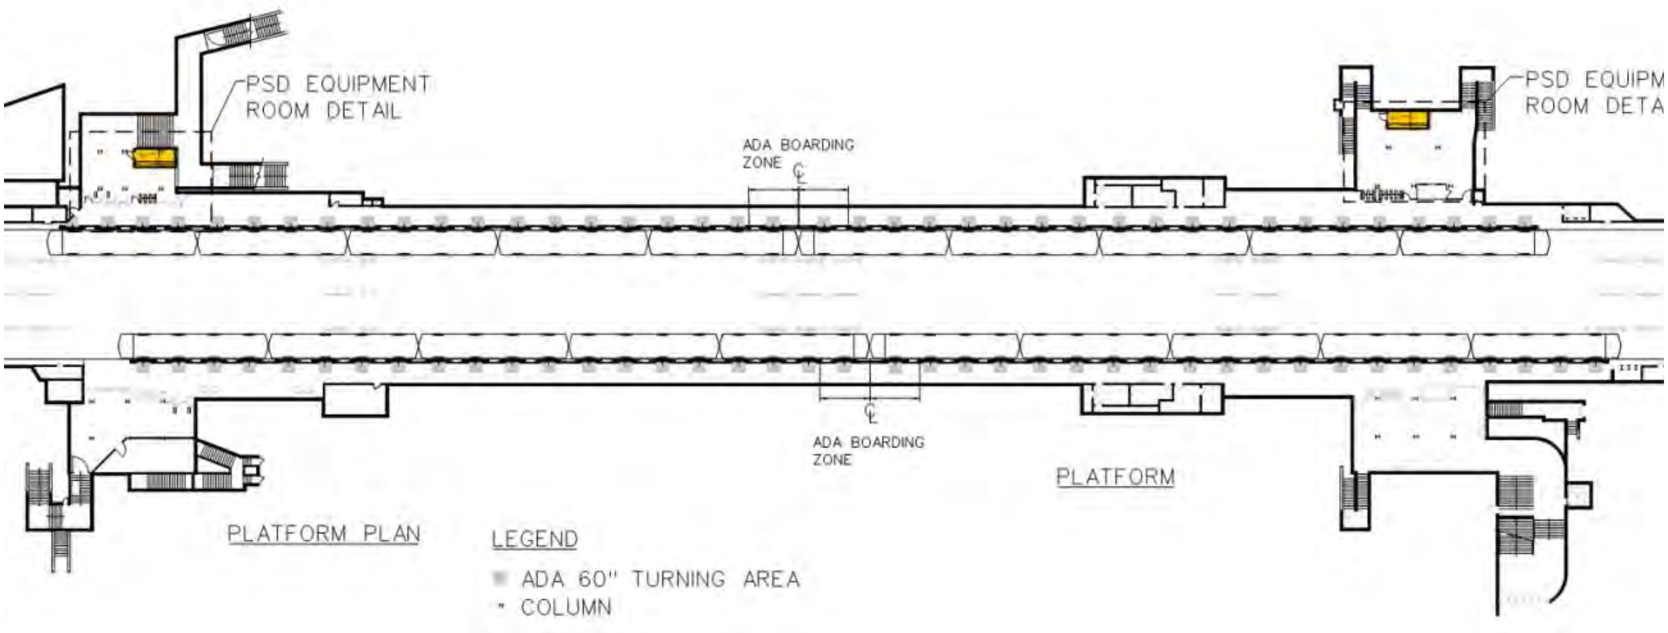

Figure 1 – Overall plan
49th Street Station

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'R' Line Stations
(49th Street Station)

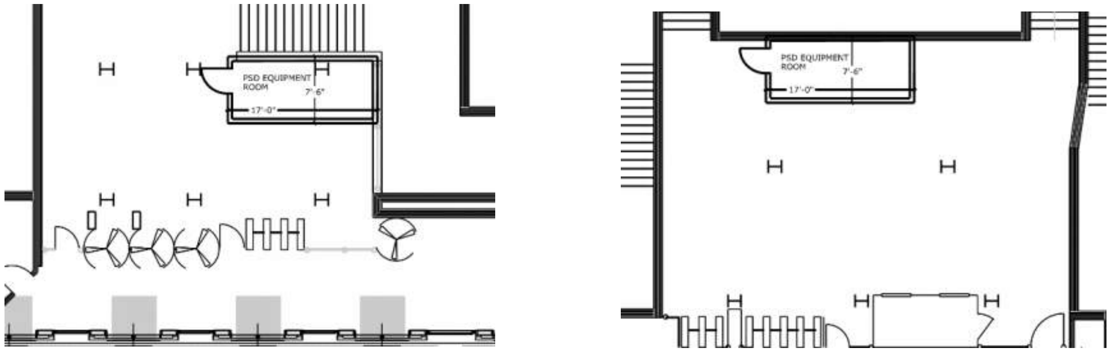

Figure 2 *– PSD Equipment Room Detail*
49th Street Station

Platform obstructions within 5' of edge:

None

Lighting:

Existing lighting: Throughout both platforms there is linear fluorescent mounted perpendicular to the platform edge in the ceiling coffers. No lighting reconfiguration will be required as part of a PSD installation.

Figure 3 *– General platform view*
49th Street Station

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	49th Street
Peak Demand Load from ConEd Report, Last **12** Months, (kW)	45.2
Apparent Power (kVA)	56.5
Station Peak Demand Load, Max Current, (A)	156.9
Maximum Number of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	352
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	449
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1-line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**. Meter reading is for 12 months.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $33.5M to install APGs and $43.5M to install PSDs (See Appendix E)

Table of Contents

1.05 – MR 011 | Times Square / 42nd Street Station

Summary: *Times Square / 42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 19" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the Shuttle, 7, 1,2,3-line for the remainder of the station)*

Description

Times Square / 42nd Street Station is a below-grade station consisting of two center / island platforms. The platform width is 19-4" throughout. The platforms are straight with two rows of columns at 3'-8" from edge of platform. At the south end of the platforms, the columns flanking an equipment room are 2'-10" from the platform edge. The implementation of a platform edge barrier would reduce this width to 19" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

***Figure 1** – Non-Compliant ADA condition*
42nd Street / Times Square Station

1.06 – MR 012 | 34th Street / Herald Square Station

Summary: *34th Street / Herald Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see the B, D, F, M-line report for the remainder of the station)*

Description

34th Street / Herald Square Station is a below-grade station consisting of two center / island platforms. The platform width is 19'-8" throughout. The platforms are straight with two rows of columns at 3'-4" from edge of platform. On the center / island platform the columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

***Figure 1** – Non-Compliant ADA condition*
34th Street Station

1.07 – MR 013 | 28th Street Station

***Summary:** 28th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

28th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-6" from the platform edge at each platform, though approximately one third of the platform is column-free. The platform width varies from 6'-0" to 9'-5. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar..

.

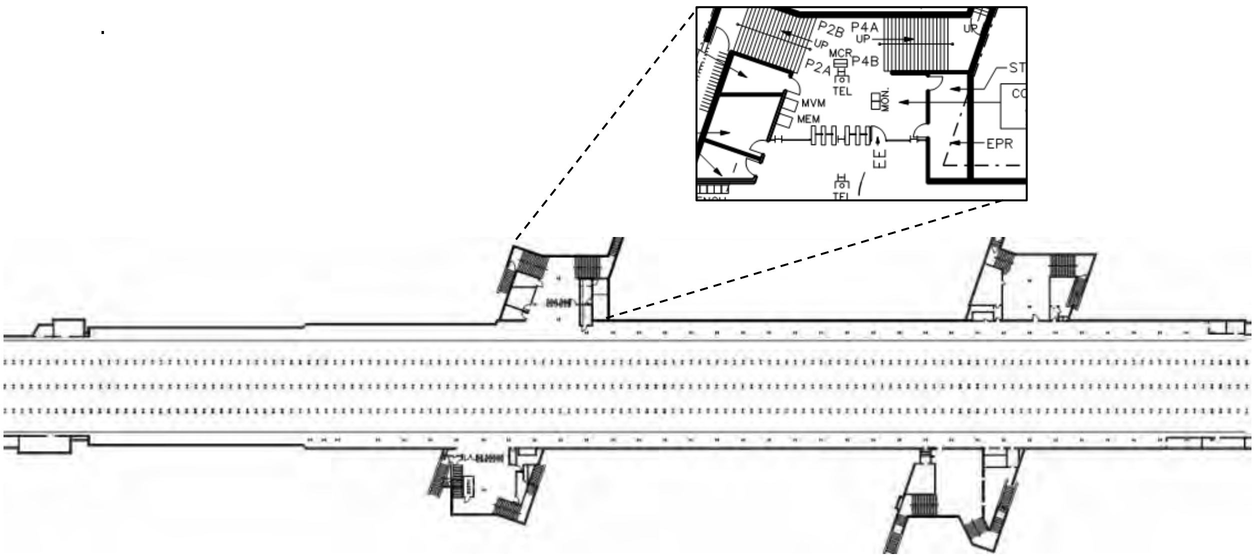

***Figure 1** – Station Plan- 28th Street Station*

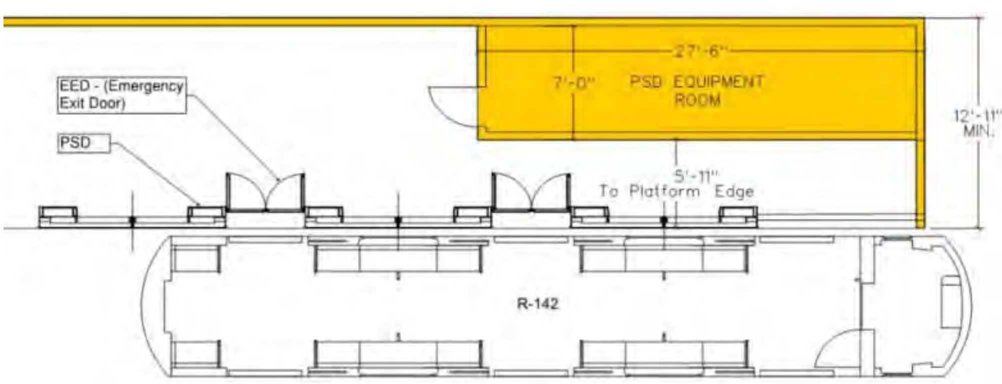

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.08 – MR 014 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound platform control area as the remaining width would be 27" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-8" from the platform edge at each platform. The platform width varies from 6'-0" to 11'-2" in width. The entry / exit turnstiles at the south entrance of the northbound platform are positioned with minimal clearance of 18" to the adjacent columns. The remaining space between the columns and the platform edge measures 42". The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figures 1and 2 below. The plan in figure 1 demonstrates that there is no alternative location for the turnstiles / railings.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

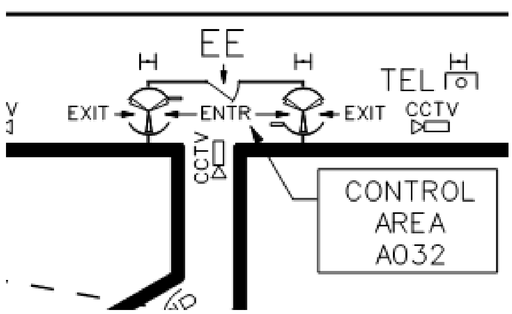

***Figure 1** – Non-Compliant ADA condition - 23rd Street*

***Figure 2** – Non-Compliant ADA condition*
23rd Street

1.09 – MR 015 | 14th Street / Union Square Station

Summary: *14th Street / Union Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the L-line and 4,5,6-line for the remainder of this complex)*

Description

14th Street / Union Square Station is a below-grade station consisting of two center / island platforms. The platform width is 18-8" throughout. The platforms are straight with two rows of columns at 3'-6" from edge of platform; these columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
14th Street / Union Square

Table of Contents

1.10 – MR 016 | 8th Street Station

Summary: *8th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

8th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-4" from the platform edge at each platform. The platform width varies from 9'-6" to 11'-0" in width. The south street stair at each platform is positioned with minimal clearance to the adjacent columns. The remaining space between the columns and the platform edge measures 40". The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
8th Street Station

Table of Contents

1.11 – MR 017 | Prince Street Station

Summary: *Prince Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

Prince Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-6' to 8'-8". Platform width at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement.. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Prince Street

1.12 – MR 018 | Canal Street Station Upper Level

Summary: *Canal Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

Canal Street Station (upper level) is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-0' to 11'-8". Platform width at the south end of the northbound platform is 48". The implementation of a platform edge barrier would reduce this width to 33" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Canal Street Station

1.13 – MR 020 | City Hall Station

Summary: *City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

City Hall Station is a below-grade station with a center / island platform. The platform structure is cast-in-place concrete. The platform width varies from 23'-8" to 46'-4". There are four lines of columns, with those adjacent to the track being 3'-4" from the platform edge. Ceiling heights measure no less than 7'-6" throughout. At the stair to the lower level, clearance along the platform edge is constricted by columns subdividing the space into two narrow widths. The available 40" width between columns and platform edge will be further constricted by the introduction of PSDs, reducing the width to 25" or less* which would not allow for ADA compliant wheelchair movement. See Figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
City Hall Station

1.14 – MR 021 | Cortlandt Street Station

Summary: *Cortlandt Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-3"" (see figure 1).*

Description

Cortlandt Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-3' to 19'-8". There are two ceiling-mounted signals at each platform at a minimum 6'-11" clearance.

Platform width at the south end of the northbound platform is 5'-3". The installation of a platform edge barrier will reduce the width to 48" or less*. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant code condition*
Cortlandt Street Station

1.15 – MR 022 | Rector Street Station

Summary: *Rector Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound control area as the remaining width would be 25" (see figure 1).*

Description

Rector Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 10'-2' to 11'-8". At the turnstile line on the northbound platform, clearance between the turnstiles and the row of columns is only 20". At this area there is 40" between the columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32" for a pinch point. The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference. The plan of this area shown in Figure 2 reveals the constrained conditions within the unpaid area and demonstrates that there is no available space for reconfiguration of turnstiles to ameliorate the non-compliant conditions.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant code condition*
Rector Street Station

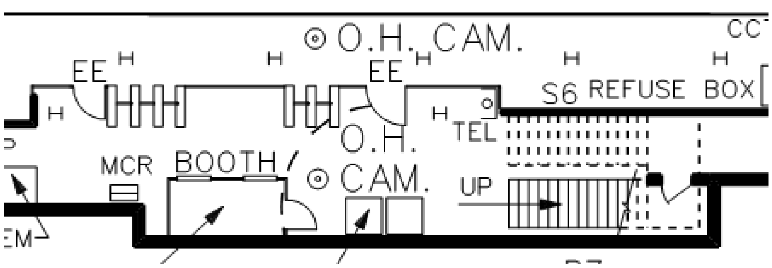

Figure 2 *– Constrained control area; northbound platform*
Rector Street Station

Table of Contents

1.16 – MR 023 | Whitehall Street Station

Summary: *Whitehall Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

Whitehall Street Station is an underground station consisting two center / island platforms. The platforms are approximately 12'-6" wide throughout. At four staircases, columns flank the stair, leaving a dimension of 36" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Whitehall Street Station

1.17 – MR 024 | Court Street Station

Summary: *Court Street is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors. (see figure 1).*

Description

The Court Street Station is a below grade station with a center / island platform. The platform structure is cast-in-place concrete. The width of the platform varies from 15'-2" to 19'-2". Several columns are 16" from the platform edge. In that position, the columns block access to the maintenance panels of the PSDs. In addition, the columns impede the ability to open the hinged emergency egress doors which are mounted between every PSD sliding door. **(see Figure 1)**.

Figure 1 – *Obstruction at platform edge*
Court Street Station

1.18 – MR 025 | Jay Street / Metrotech Station

Summary: *Jay Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36” minimum corridor width and the 32” minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 9” (see figure 1).*

Description

The Jay Street Station is a below grade station with a center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 14’-0” throughout. Columns are spaced 13’-0” on center. There is one staircase along the platform adjacent to these columns. The column faces are 24” away from all platform edges. The implementation of a platform edge barrier would reduce this width to 9”” or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
Jay Street Station

1.19 – MR 026 | Dekalb Ave Station

Summary: *Dekalb Ave Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

Dekalb Ave Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. The platform columns are spaced 10'-10" on center, and column faces typically measure 3'-8" from the platform edge. The platform width is 15'-8" throughout. At the platform staircases, the columns flanking the stairs measure 3'-8" from the platform edge and are touching the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 44" to 29" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

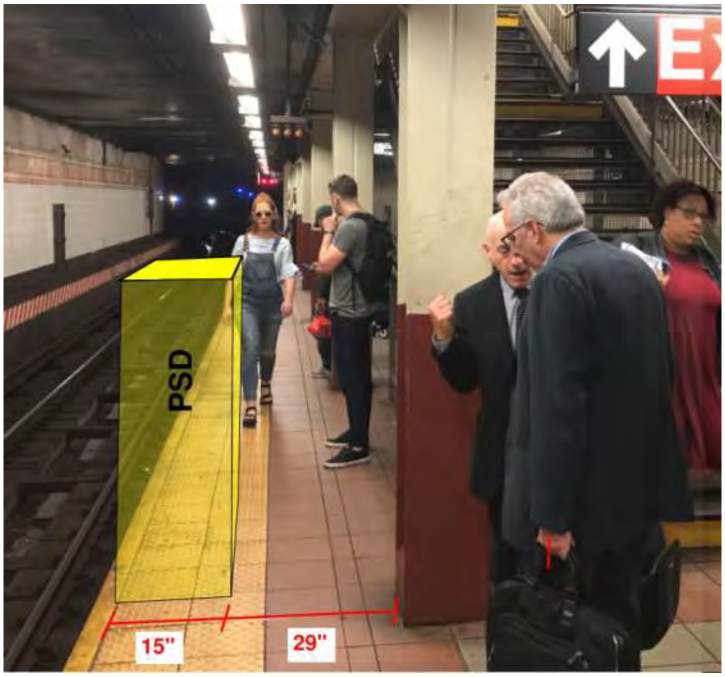

Figure 1 *– Non-Compliant ADA condition Dekalb Avenue Station*

1.20 – MR 027 | Atlantic Ave Station

Summary: *Atlantic Ave Station is feasible for both APGs and PSDs. At the southbound platform, two columns adjacent to the platform edge would require removal and replacement at a more distant location. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Atlantic Ave Station is a below grade with two side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are spaced 15'-1/2" on center, and column faces are at varying distances from the platform edge. The platform width is 18'-8" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the south mezzanine. (**Figure 1 & Figure 2).** The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

This platform edge was re-constructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'R' Line Stations
(Atlantic Ave Station)

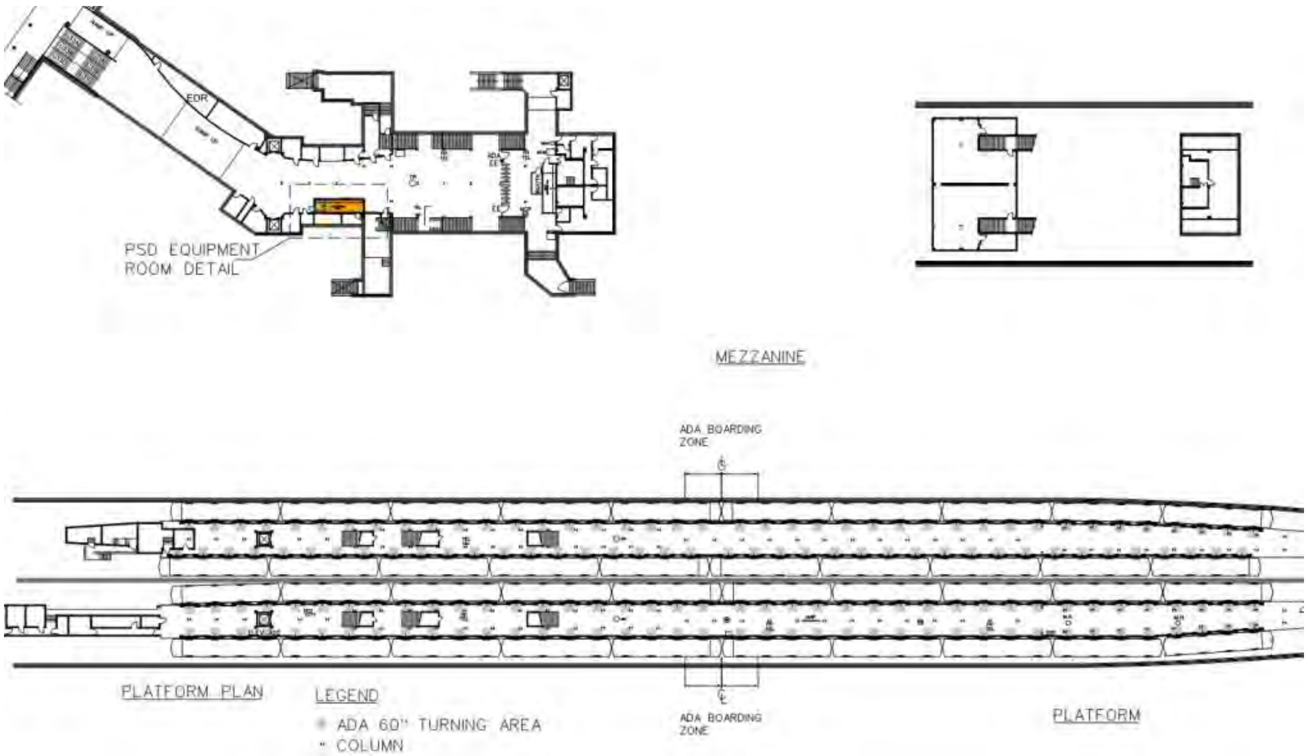

Figure 1 *– Overall Station Plan*
Atlantic Ave Station

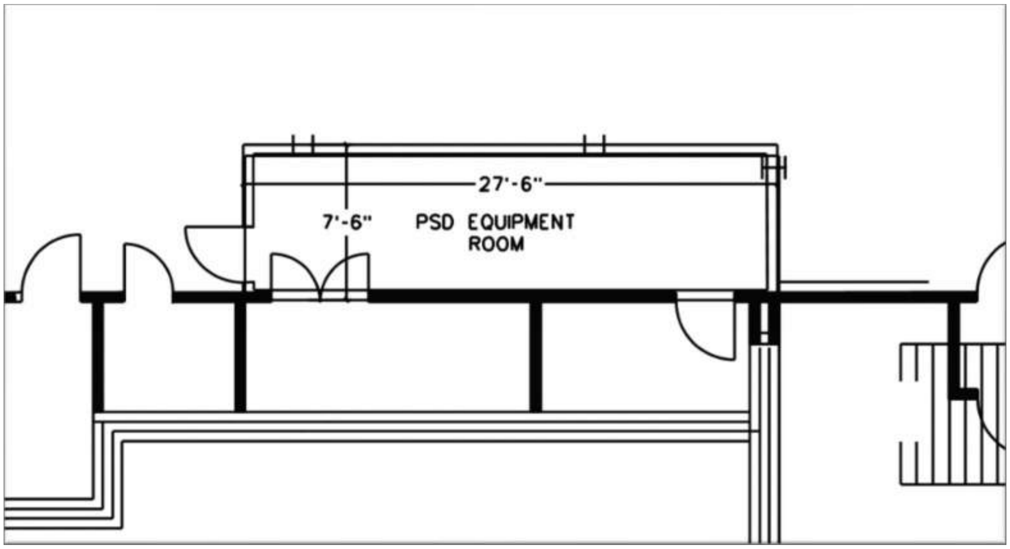

Figure 2 *– PSD Equipment Room 1 Detail*
Atlantic Ave Station

Platform obstructions within 5' of edge:

Southbound Track:

- One column is at 1'-0" from each platform edge. They will require removal and replacement as part of any PSD installation.

Northbound Track:

- None

These obstructions do not present an impediment to the installation of PSDs beyond the instances mentioned above.

Historic Restrictions:

The Atlantic Avenue station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis

Station Name	Atlantic Ave. Barclays Ctr.
Peak Demand Load from ConEd Report, (kW)	88.8
Apparent Power (kVA)	111.0
Station Peak Demand Load, Max Current, (A)	308.3
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	649
Station Service Power Capacity, (Main SB or SG Rating), (A)	1600
Service Spare Capacity, (A)	951
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 1600A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service. This analysis is for **Normal service**.

Table 1- *Power Capacity Analysis (Normal Service)*

Station Power Capacity Analysis

NYCT Station MR Number	27
Station Name	Atlantic Ave. Barclays Ctr.
Peak Demand Load from ConEd Report, (kW)	55.2
Apparent Power (kVA)	69.0
Station Peak Demand Load, Max Current, (A)	191.7
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	532
Station Service Power Capacity, (Main SB or SG Rating), (A)	1600
Service Spare Capacity, (A)	1068
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 1600A fuses at Service switch. Station has (2) separate meter readings each for Normal & Reserve service. This analysis is for **Reserve service**.

Table 1- *Power Capacity Analysis (Reserve Service)*

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.3M to install APGs and $39.9M to install PSDs (See Appendix E).

***Figure 3** – View of column at platform edge requiring removal and replacement*
Atlantic Ave Station

1.21 – MR 028 | Union Street Station

Summary: *Union Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Union Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 2’-6” from the platform edge at each platform, at the northern third of the stations. The remainder of the platform is column-free. The platform width is 8’-8” throughout. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2 below shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

.

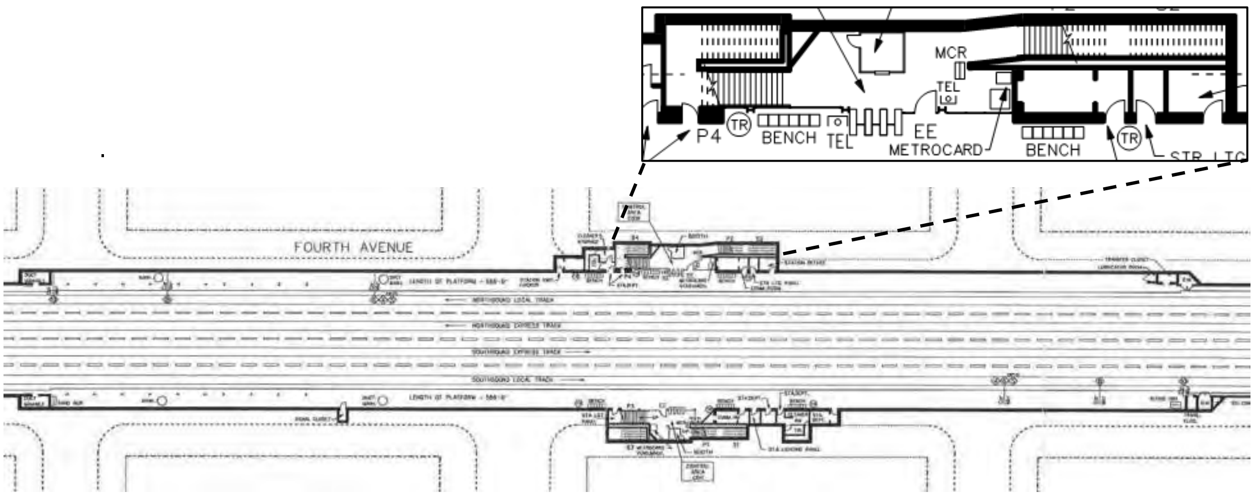

Figure 1 – *Congested/Narrow Station Plan*
Union Street Station

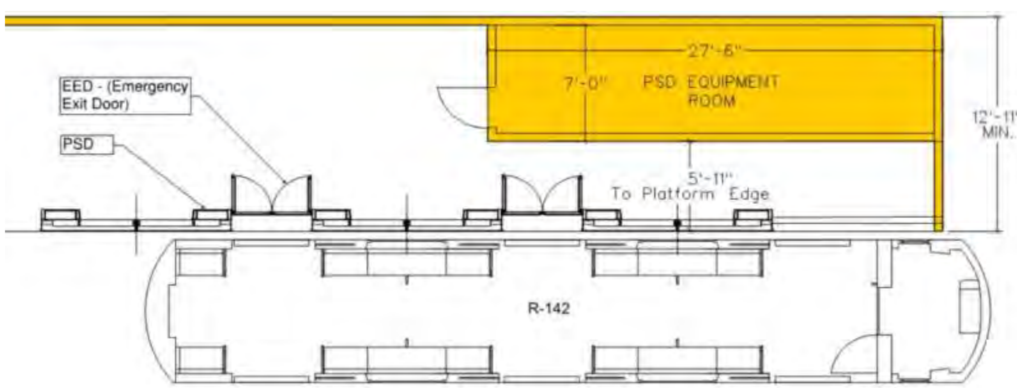

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
Union Street Station

1.22 – MR 029 | 4th Ave / 9th St Station

Summary: *4th Ave / 9th St Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

4th Ave 9th St Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 8'-4" to 8'-8"." Columns are spaced 11'-10" on center with column faces 3'-0" away from the edge. The columns are present only on the northern third of both the platforms; the remainder of the platforms are column-free. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

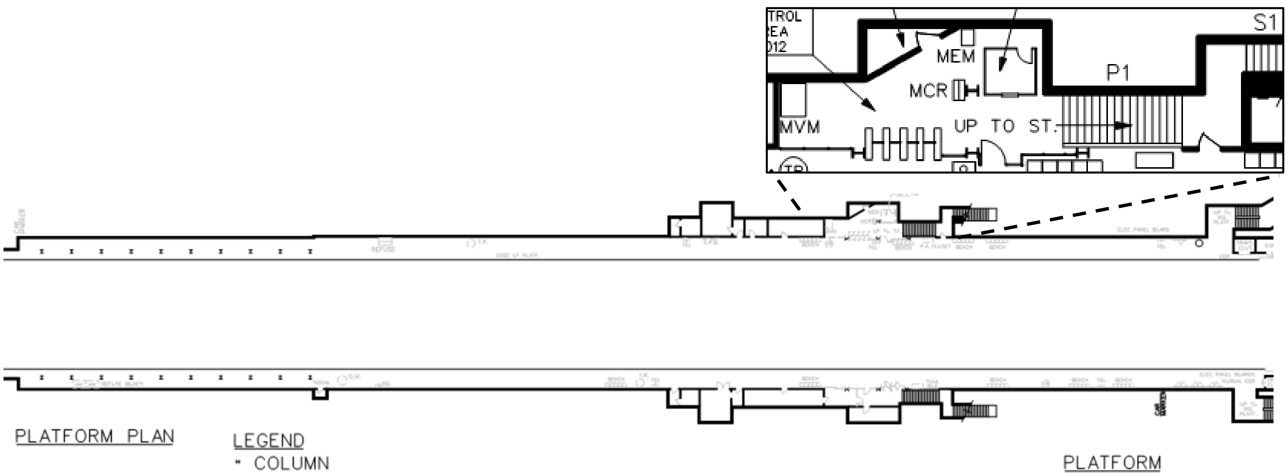

Figure 1 – *Congested/Narrow Station Plan*
4th Ave / 9th Street Station

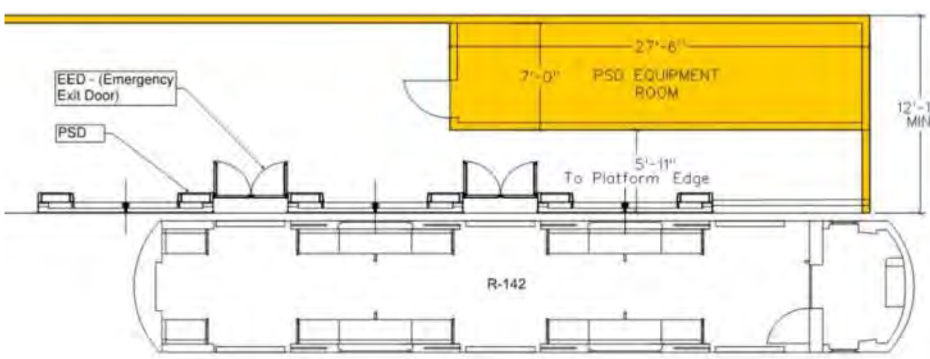

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
4th Ave / 9th Street Station

1.23 – MR 030 | Prospect Avenue Station

Summary: *Prospect Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

The Prospect Ave Station is a below-grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms and control areas, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

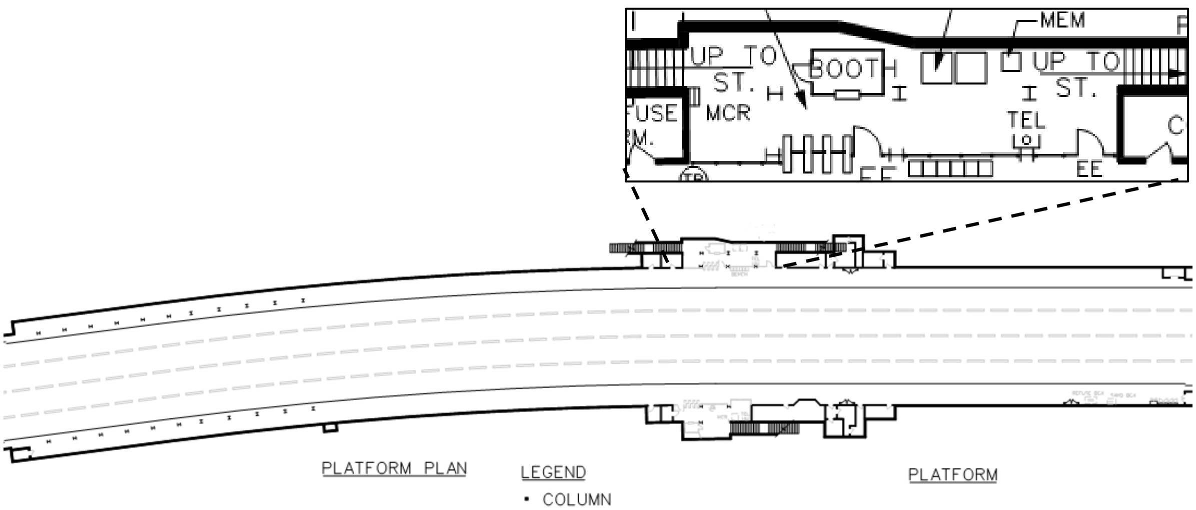

***Figure 1** – Congested/Narrow Station Plan*
Prospect Avenue Station

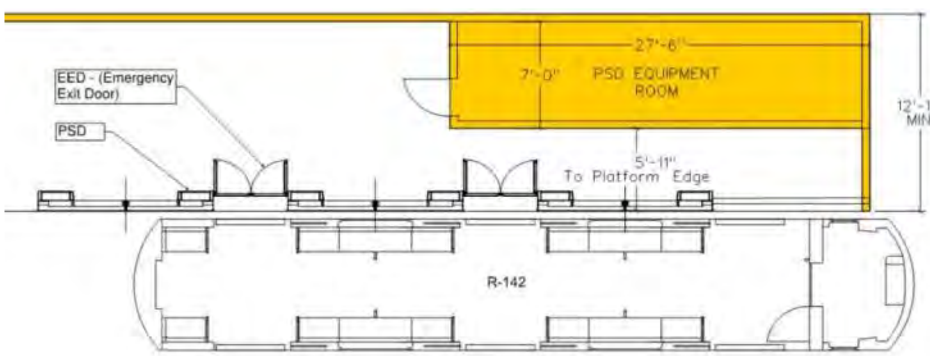

***Figure 2** – Diagram demonstrating minimum platform width dimensions*
Prospect Avenue Station

1.24 – MR 031 | 25th Street Station

Summary: *25th Street is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

25th Street Station is a below grade station with two side platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 8'-4" throughout. Columns occupy only the northern third of the platforms with column faces 2'-4" away from the platform edge. Due to the extremely limited width of the existing platforms, there is no available space for an equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the northbound control area. The southbound control area is similar.

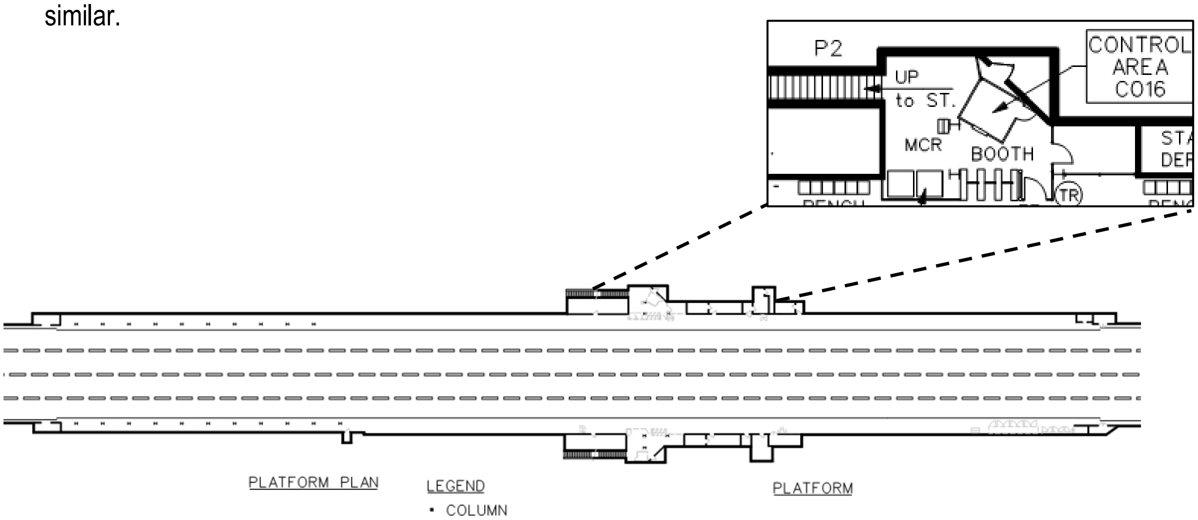

***Figure 1** – Congested/Narrow Station Plan*
25th Street Station

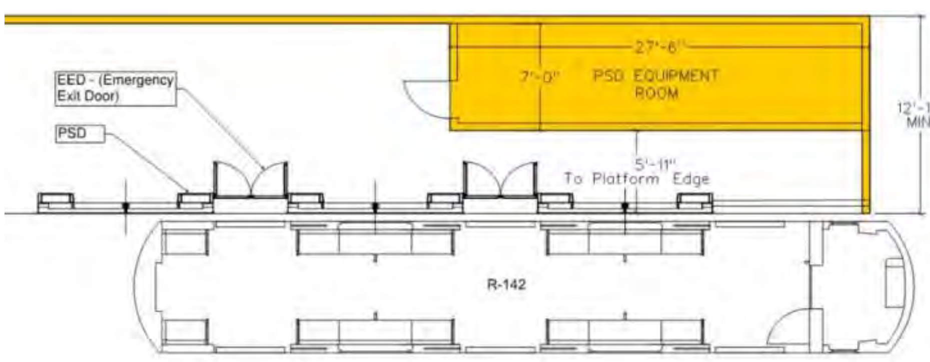

***Figure 2** – Diagram demonstrating minimum platform width dimensions*
25th Street Station

1.25 – MR 032 | 36th Street Station

Summary: *36th Street Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors. (see figure 1).*

Description

The 36th Street Station is a below grade station with two center / island platforms. The platform structure is cast-in-place concrete. The width of the platforms varies from 13'-0" to 19'-2". The station is not feasible for both APGs and PSDs due to the presence of structural columns located on the station platforms which are within the envelope that the proposed PSD system(s) would occupy. Due to the position of columns at 12" or less from the platform edge, installation and maintenance cannot be carried out for lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios. **(see Figure 1)**.

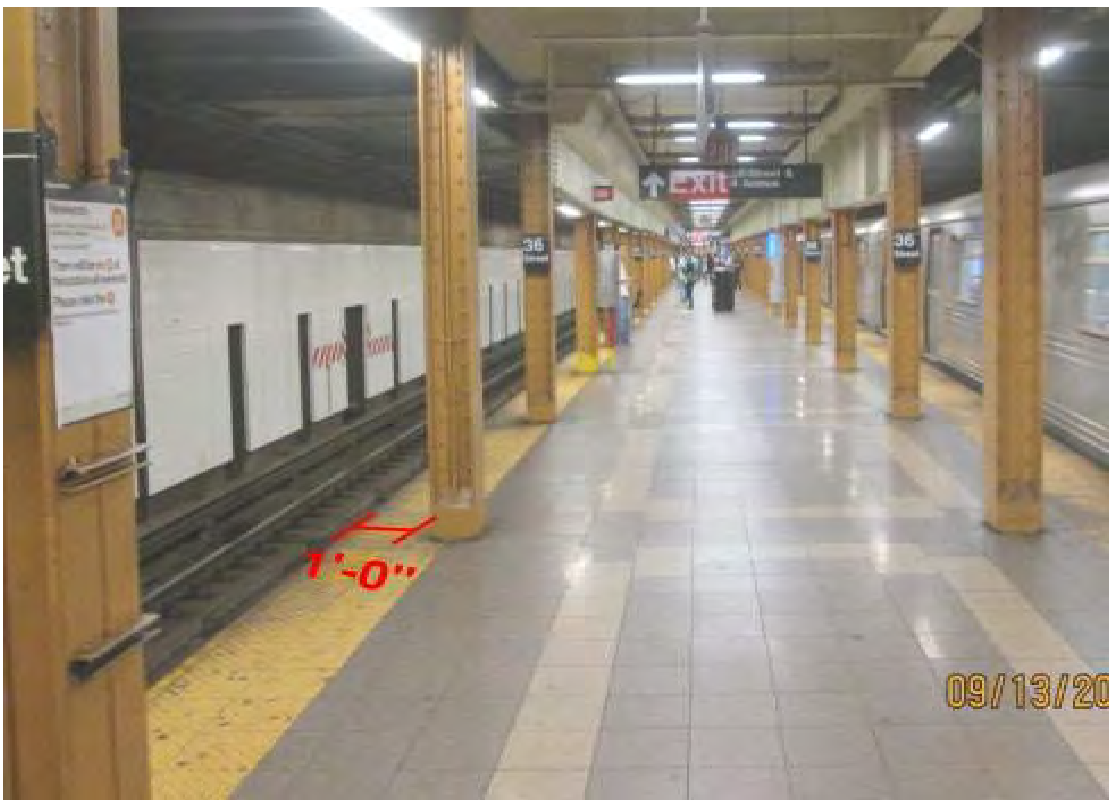

Figure 1 – *Obstruction within 12"*
36th Street

1.26 – MR 033 | 45th Street Station

Summary: *45th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs/walls as the remaining width would be 25" (see figure 1).*

Description

The 45th Street Station is a below grade station with two side straight platforms. The platform structure is cast-in-place concrete. The width of the platform varies 10'-8" to 15'-6". There is one room along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-6" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
45th Street Station

1.27 – MR 034 | 53rd Street Station

Summary: *53rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs/wall as the remaining width would be 23" (see figure 1).*

Description

The 53rd Street Station is a below grade station with two side straight platforms. The platform structure is cast-in-place concrete. The width of the platform varies 9'-6" to 10'-10". There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-2" on center with column faces 3'-2" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Non-Compliant ADA condition*
53rd Street Station

1.28 – MR 035 | 59th Street Station

Summary: *59th Street Station not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 33" (see figure 1).*

Description

The 59th Street Station is a below grade station with two center / island platforms. The platform structure is cast-in-place concrete. The width of the platform is varying 12'-8" to 17'-10". There is one staircase along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15'-1" on center with column faces 3'-0" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

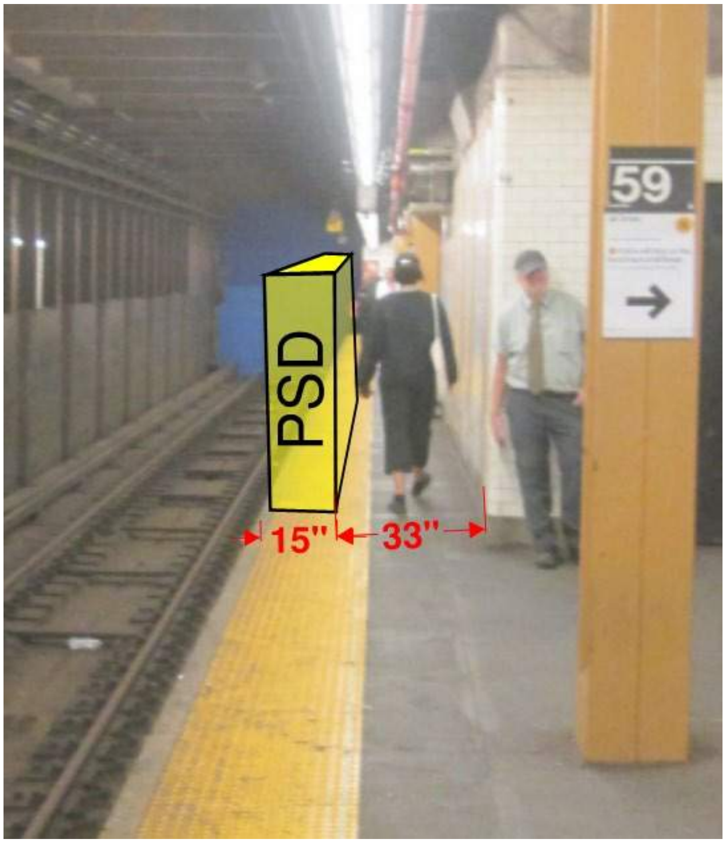

Figure 1 – *Non-Compliant ADA condition*
59th Street Station

1.29 – MR 036 | Bay Ridge Avenue Station

Summary: *Bay Ridge Avenue Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Bay Ridge Avenue Station is not feasible for both APGs and *PSDs* due to the presence of structural columns located on the station platforms which are within the envelope that the proposed PSD system(s) would occupy. Due to the position of columns at 14" or less from the platform edge, installation and maintenance cannot be carried out for lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 1'-2" from the edge*
Bay Ridge Avenue Station

1.30 – MR 037 | 77th Street Station

Summary: *77th Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

77th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns located on the station platforms which are within the envelope that the proposed PSD system(s) would occupy. Due to the position of columns at 14" or less from the platform edge, installation and maintenance cannot be carried out for lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

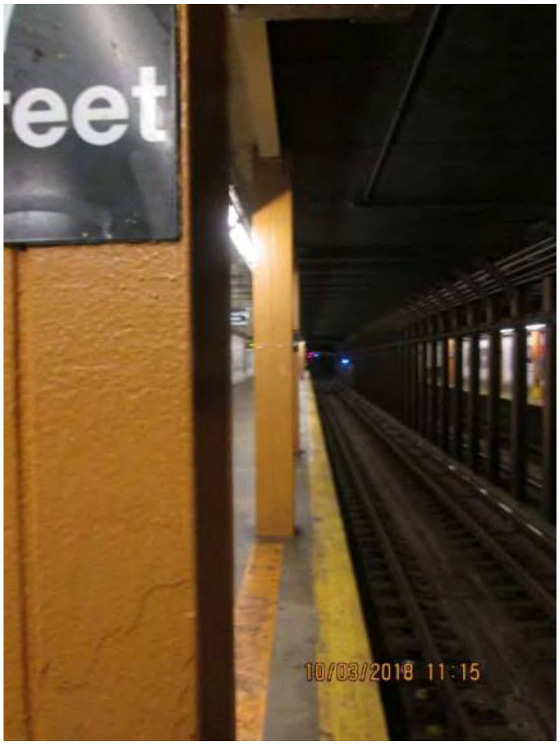

Figure 1 – *Columns 1'-2" from the edge*
77th Street Station

1.31 – MR 038 | 86th Street Station

Summary: *86th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

86th Street Station is a below-grade station with one center/island platforms. The platform structure is cast-in-place concrete. The width of the platform is approximately 18'-8" throughout. The platform width between the platform edge and a station facility room is 48". The implementation of a platform edge barrier would reduce this width below the required minimum corridor width of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1 –** Non compliant ADA Condition*
86th Street Station

Table of Contents

1.32 – MR 039 | 95th Street Station

***Summary**: 95th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 21" (see figure 1.*

Description

95th Street Station is a below-grade station consisting of one center/island platform. The platform width is approximately 16'-1" throughout. The platform is straight with two rows of columns approximately 3'-1" from the edge of platform. Columns at the ejector room at the north end of the platform measure 36" from the platform edge. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.

k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.

l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

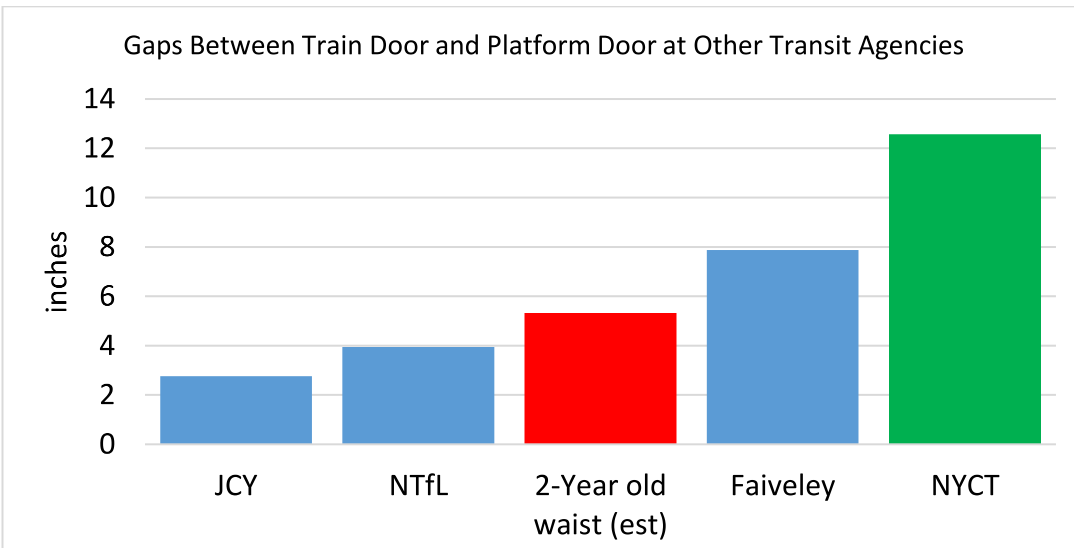

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

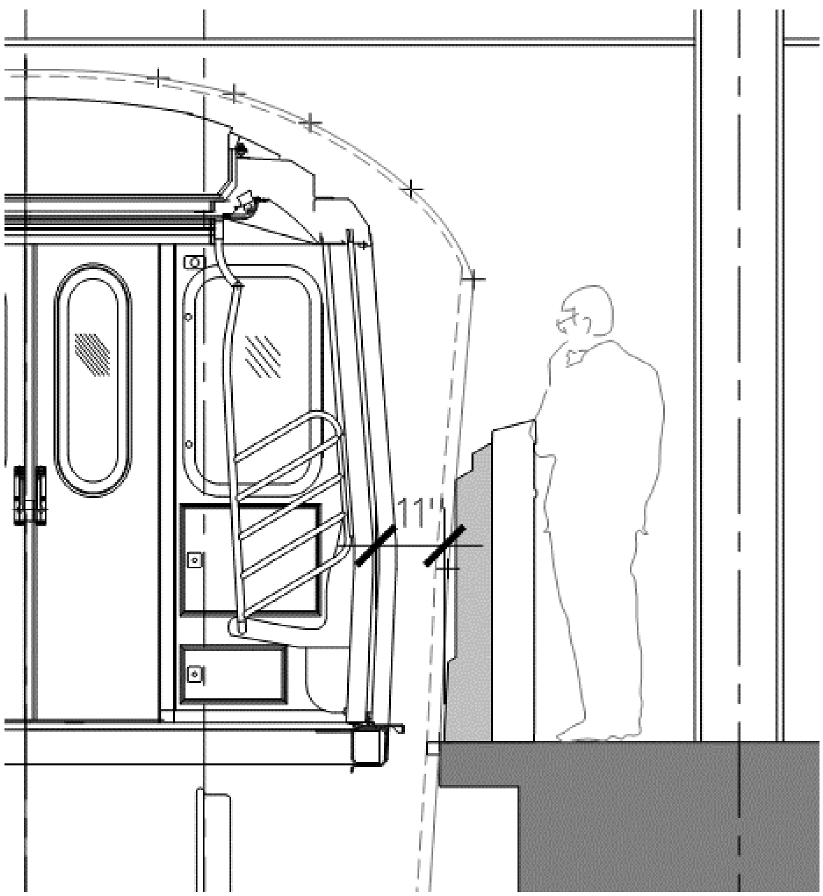

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

Impact per station

2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

Impact per station

3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

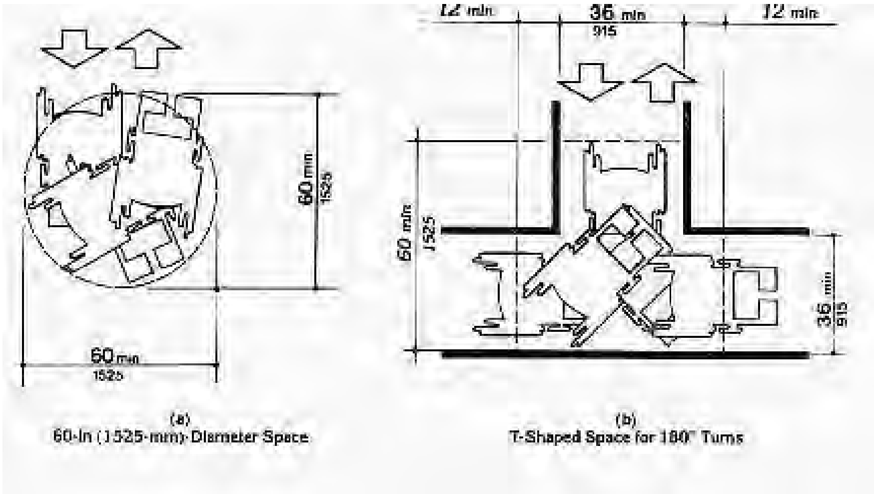
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

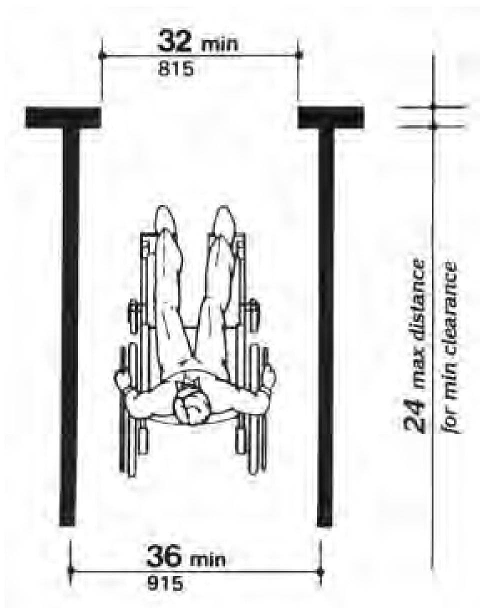


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For <u>all</u> the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

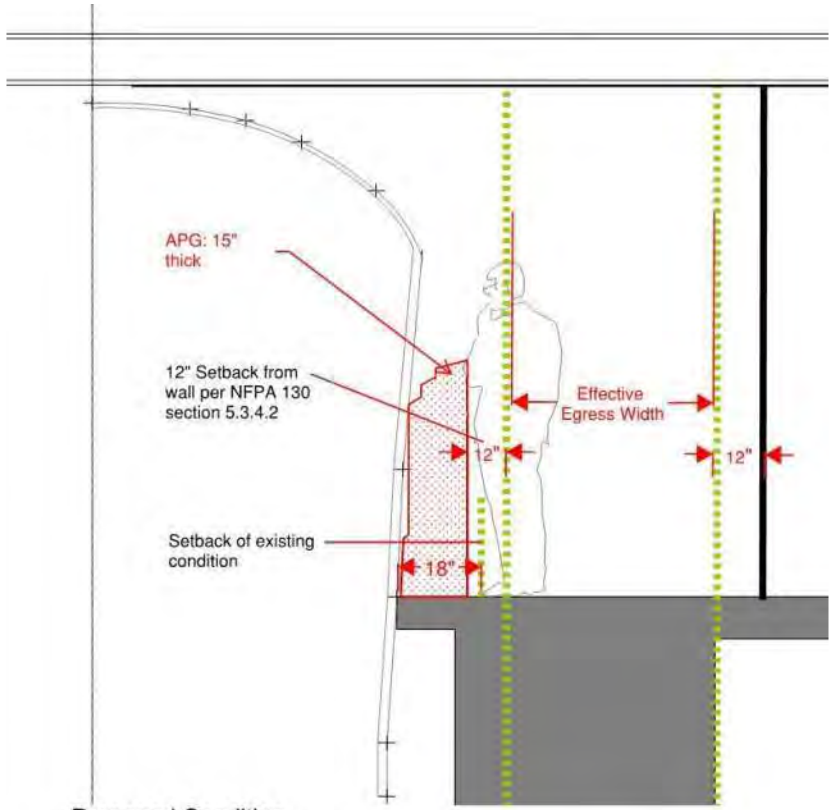
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

Table of Contents Appendix Table of Contents

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.
B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.
C. Dwell during passenger boarding/alighting
D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.
E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.

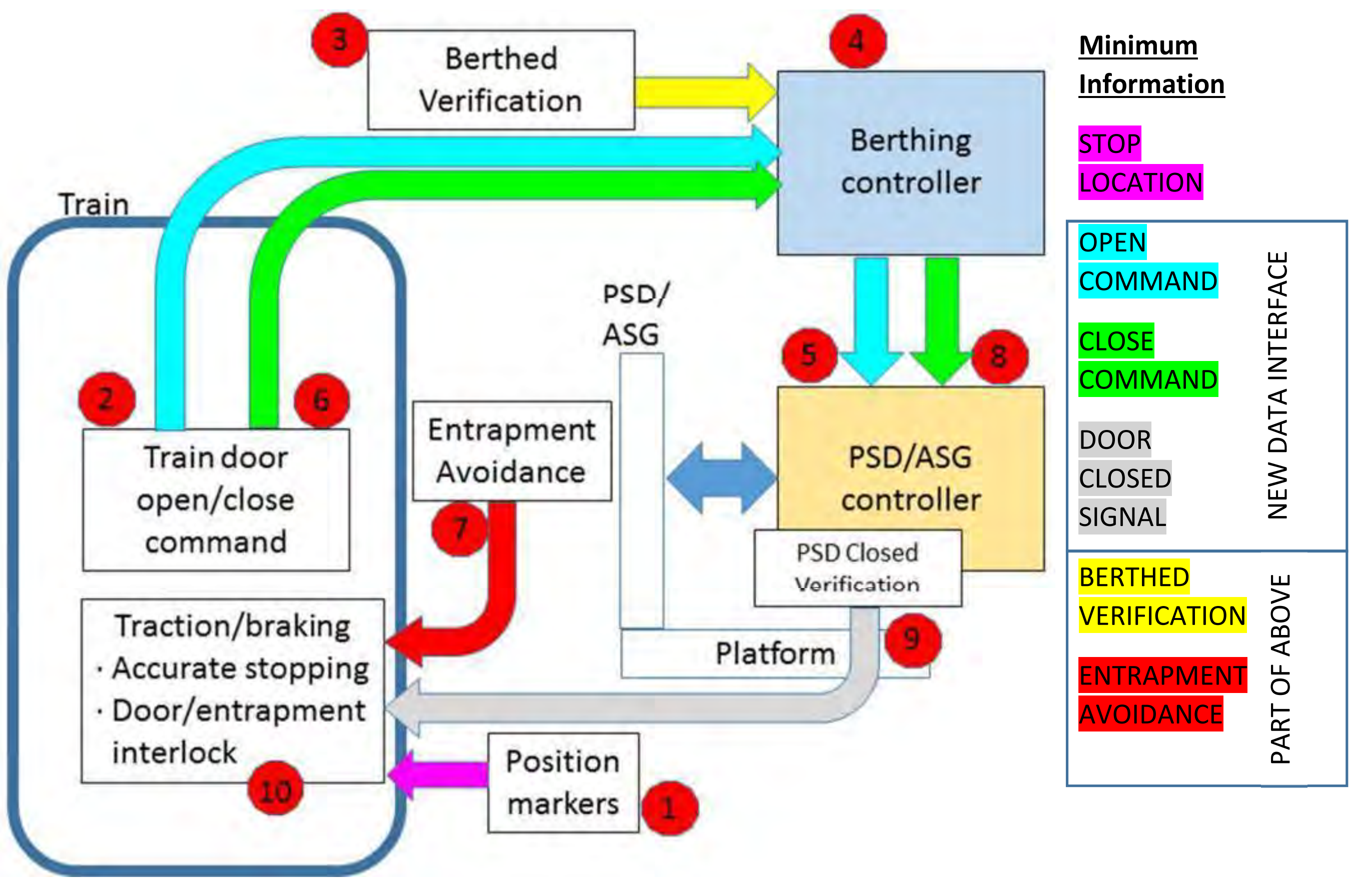

Table of Contents Appendix Table of Contents

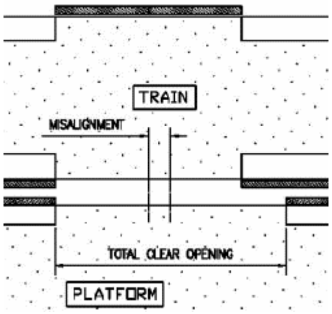
Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Table of Contents Appendix Table of Contents

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

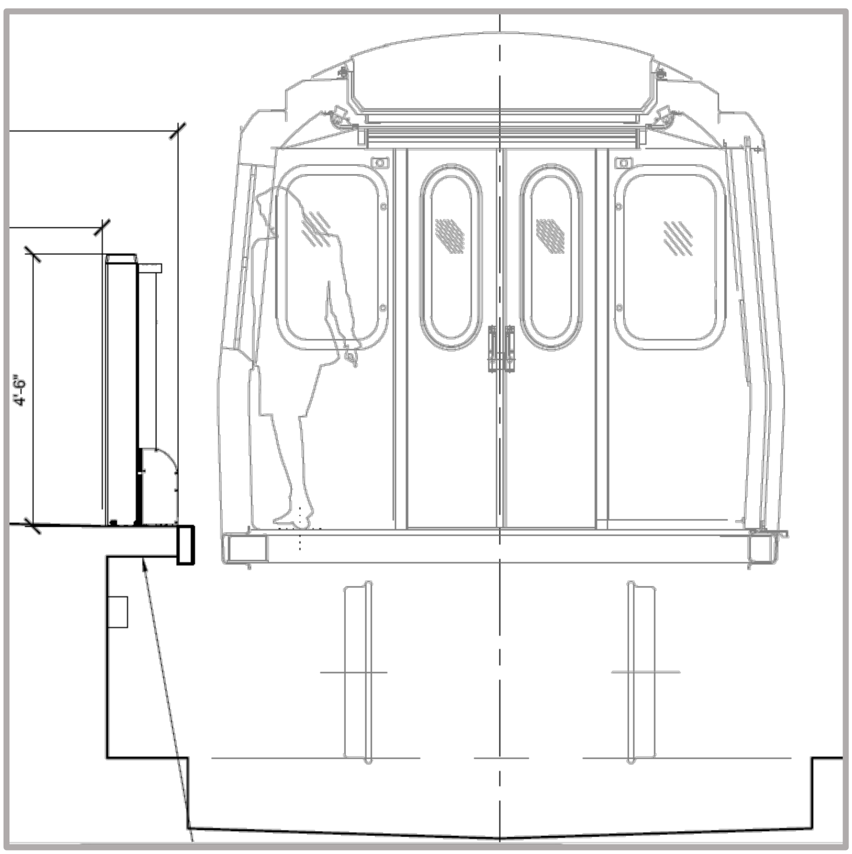


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

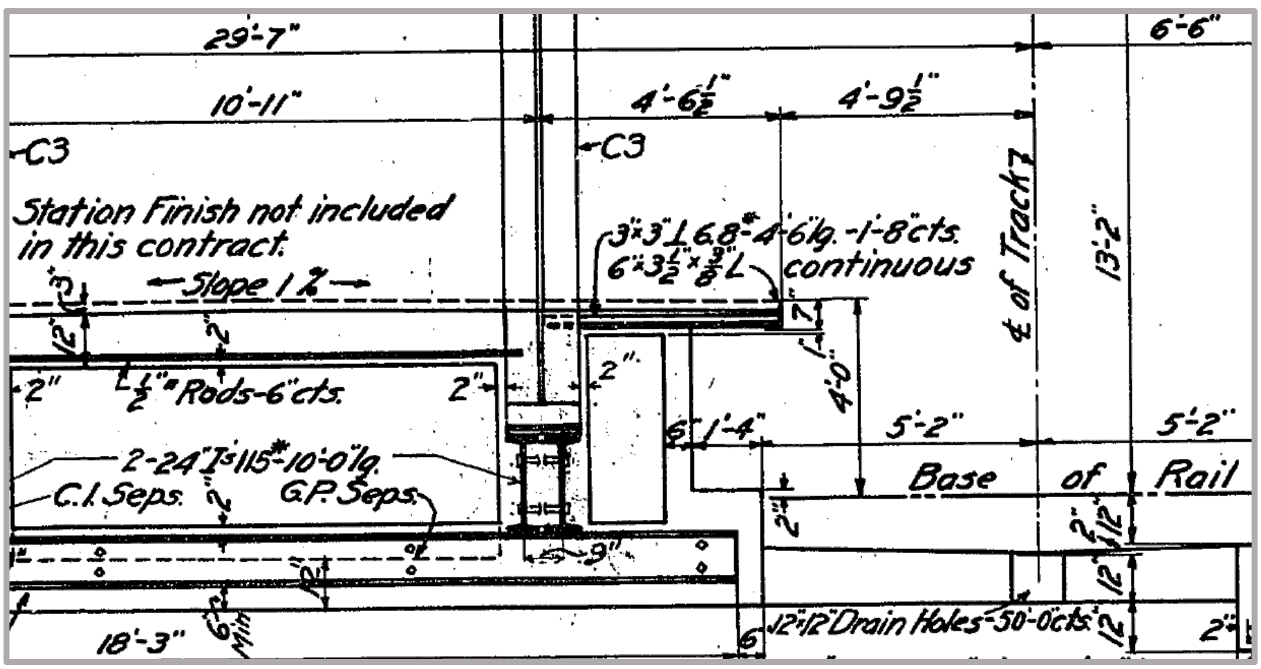

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

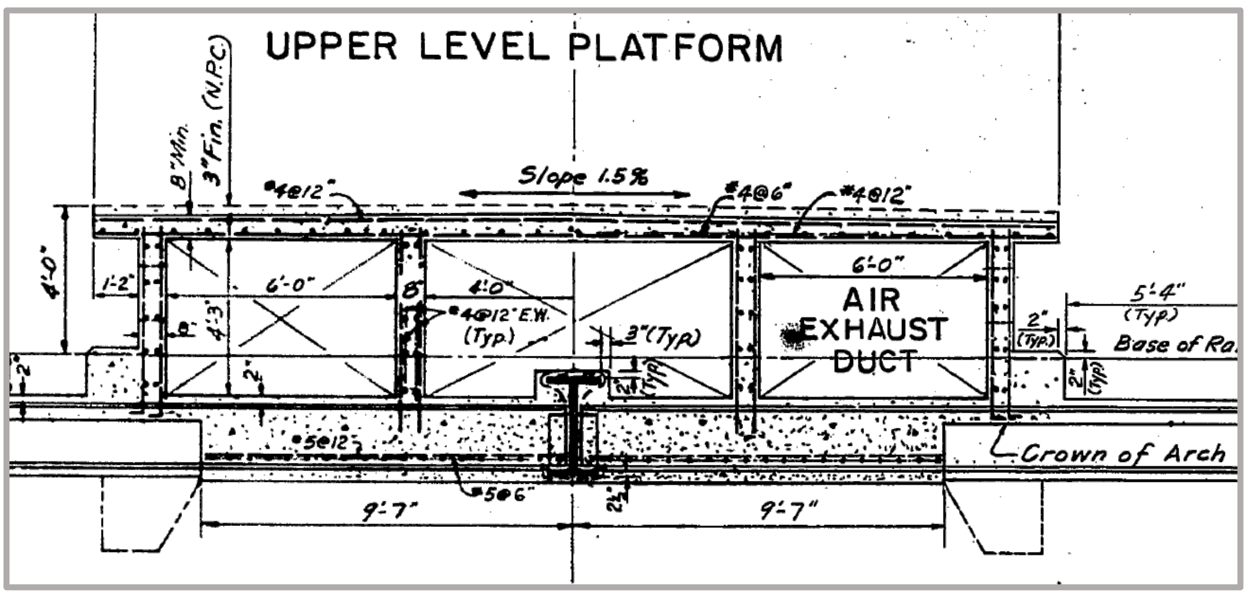

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

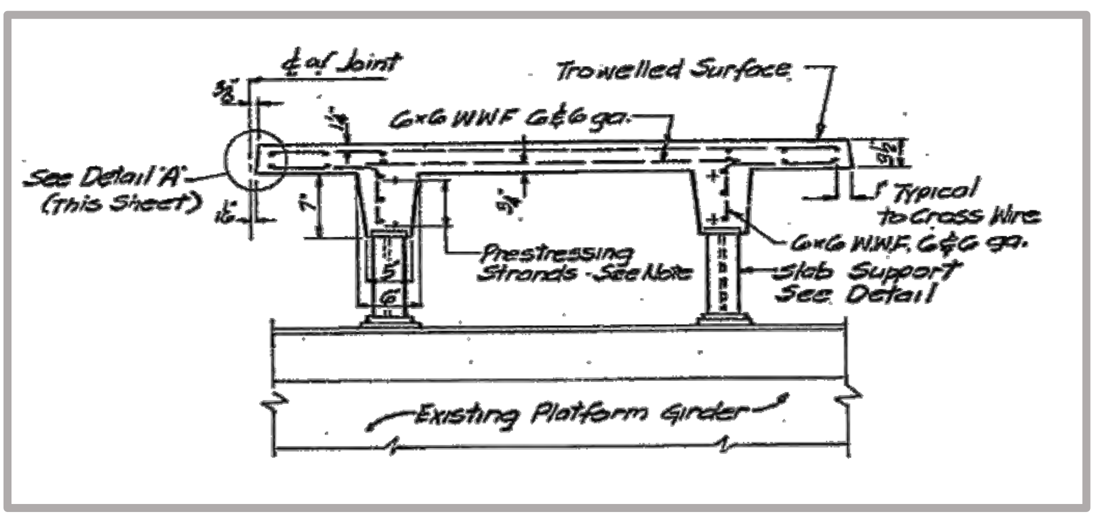

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

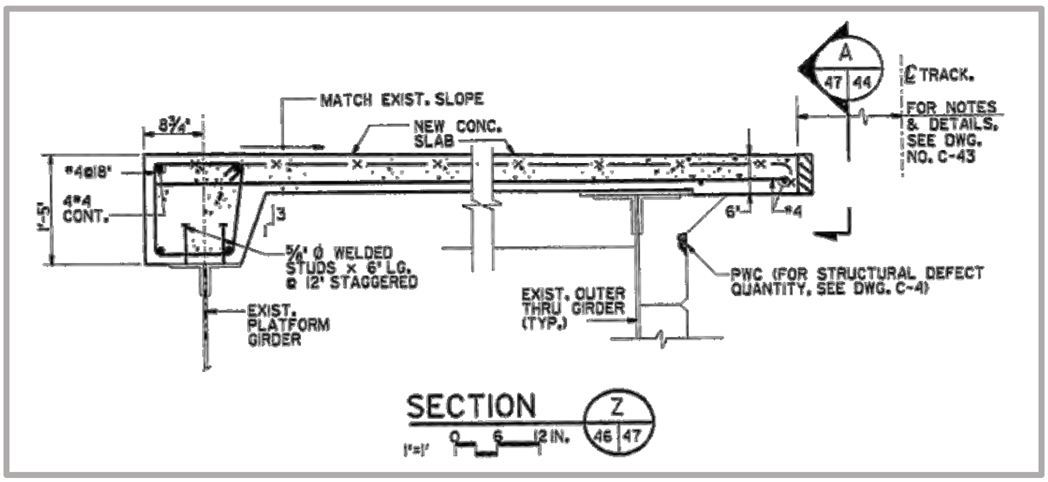

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

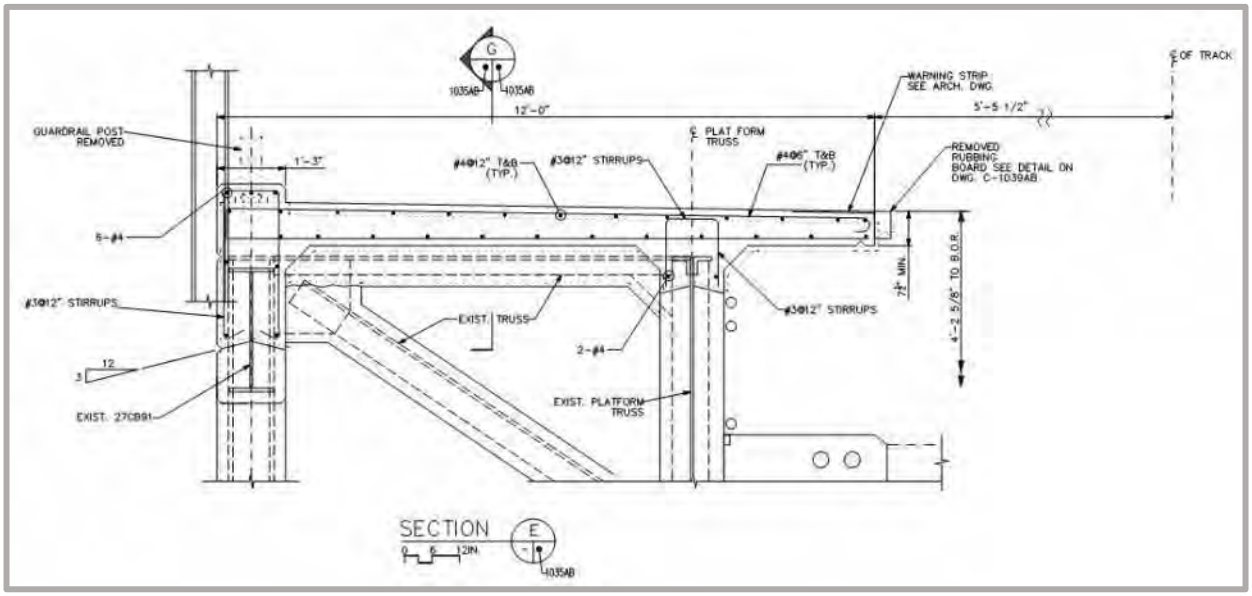

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

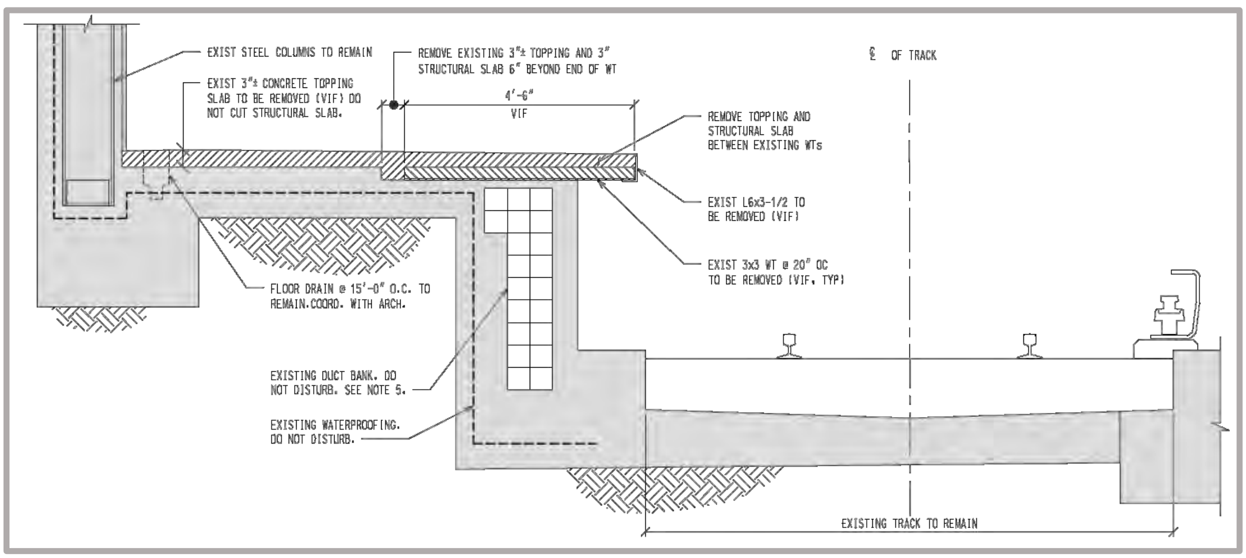

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

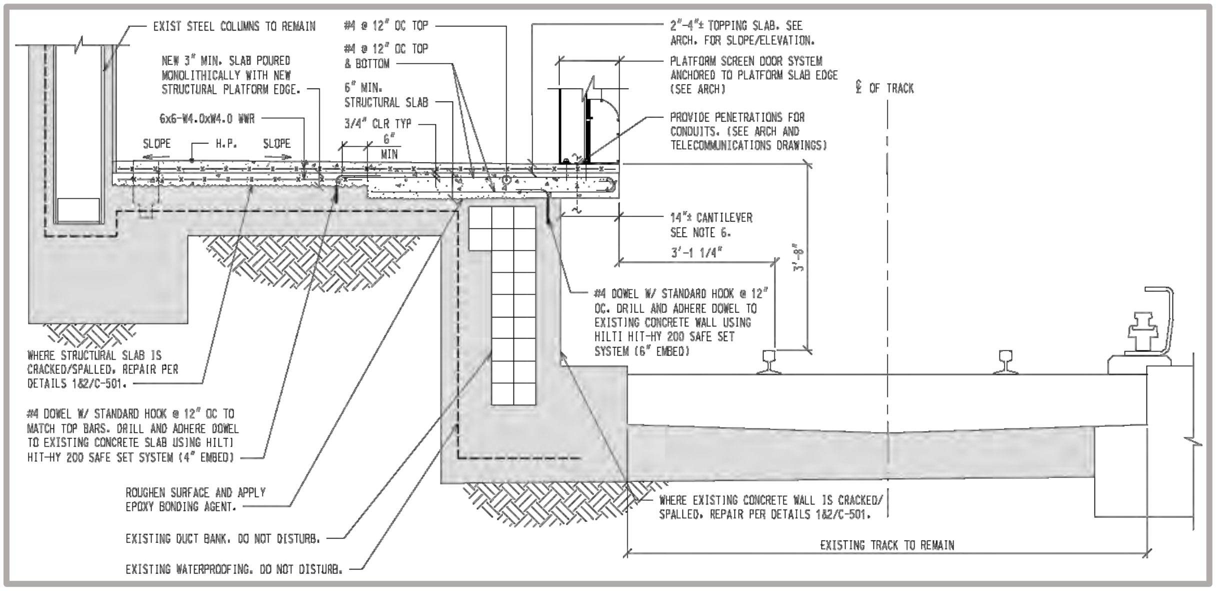

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

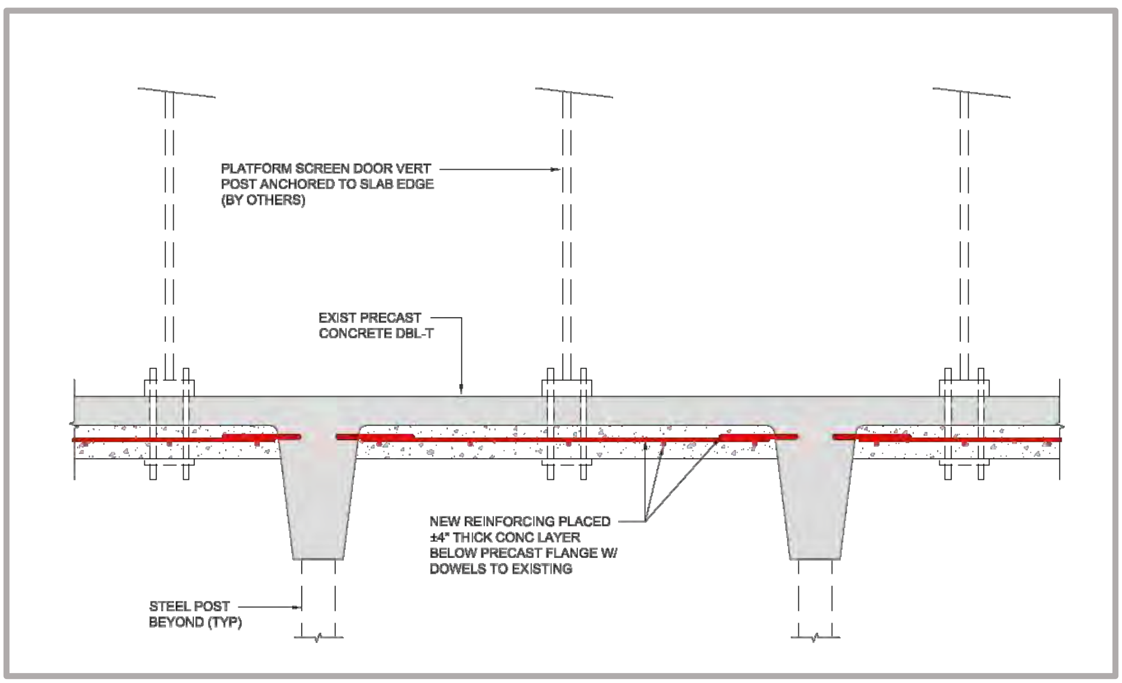

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Emergency Egress Width Analysis

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

MTA/NYCT

June 12, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 50 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10” x 10” H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

MTA/NYCT

June 12, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

12-Jun-19

STATION : 5TH AVE./59TH ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	615	LF		
5	LENGTH OF THE PLATFORM EDGE [ASTORIA BOUND] =	615	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,230**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,230	LF	7	8,610
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,150	SF	12	73,800
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	124	CY	2,500	310,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,232	EA	25	30,800
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,232	EA	25	30,800
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,230	LF	95	116,850
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,230	LF	15	18,450
26	Remove existing platform tiles	1,230	LF	12	14,760
27	Sawcut existing topping concrete at perimeter of removal area	1,230	LF	5	6,150
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,380	SF	8	59,040
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,230	SF	15	18,450

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

12-Jun-19

STATION : 5TH AVE./59TH ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	480	SF	15	7,200
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	480	LF	110	52,800
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room A [7'-6" x 27'-0"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,780
39	CMU Wall for equipment room	420	SF	45	18,900
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	203	SF	30	6,075
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	420	SF	40	16,800
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	5,040
46	Concrete cove to match existing	42	LF	20	840
47	Interior Wall Finish - Paint	420	SF	5	2,100
48	Allow for Misc. floor & ceiling finishes	203	SF	15	3,038
49	Allow for 4" thick concrete pads for equipment	51	SF	20	1,013
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 4 Doors = 40 No. per platform)	80	EA	15,000	1,200,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #39 per Platform	78	EA	10,500	819,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,250	SF	750	1,687,500
61	Spare Parts - Approx. 10% of Material Cost	1	LS	227,910	227,910
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	80	EA	2,500	200,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

12-Jun-19

STATION : 5TH AVE./59TH ST.

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,230	LF	60	73,800
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	700	LF	60	42,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	750	LF	60	45,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	100	EA	12,000	1,200,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	240	EA	4,629	1,111,018
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	240	EA	5,566	1,335,735
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for R - Line Stations

12-Jun-19

STATION : 49TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	703	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	703	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,406**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,406	LF	7	9,842
14	Remove 5' wide section of 3" deep structural slab to platform edge	7,030	SF	12	84,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	142	CY	2,500	355,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,408	EA	25	35,200
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,408	EA	25	35,200
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'W' LINE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: January 11, 2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 23 newly evaluated stations, 20 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide or greater. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Stations are found to be infeasible where these PSDs:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at the W line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings, and shows that platform edge barriers are feasible at 13% of the 'W' Line stations. Total implementation cost would be $97.7M for APGs and $83.5M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 3 feasible stations, the aggregate annual maintenance cost would be $2.8M.

Summary Table

1.0 Station Assessments

Table of Contents

1.01 – MR 001 | Astoria Ditmars Boulevard Station

Summary: *Astoria Ditmars Boulevard Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Astoria Ditmars Boulevard Station is an elevated station consisting of a center / island platform. The platform structure is precast concrete. The width of the platform is 15'-0" throughout. There are two staircases at the center of the platform. The platform is straight with two rows of a columns supporting the station canopy. Column faces measure 3'-0" from the platform edge throughout. The canopy covers the center third of the platform. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Astoria Ditmars Boulevard Station

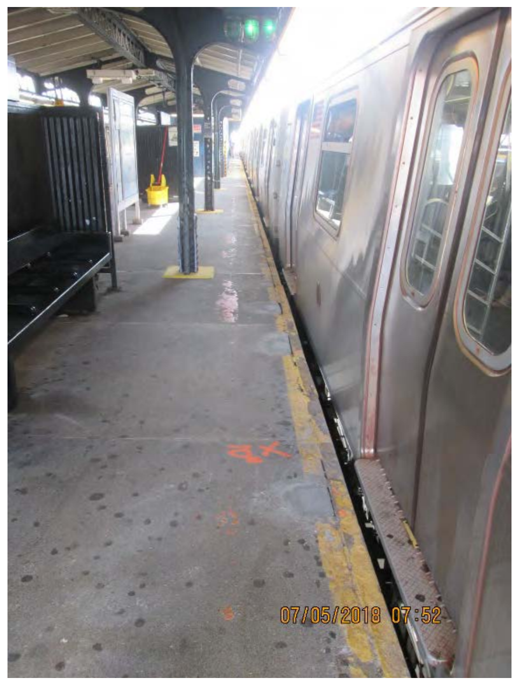

Figure 2 *– Precast Slab Seams*
Astoria Ditmars Boulevard Station

1.02 – MR 002 | Astoria Boulevard Station

Summary: *Astoria Boulevard Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Astoria Boulevard Station is an elevated station with two center / island platforms. The platform structures are precast concrete. The width of the platforms is 17'-8" throughout. There are two staircases at the center of the platforms. The platforms are straight with two rows of a columns supporting their respective station canopies. Column faces measure 3'-4" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Astoria Boulevard Station

Figure 2 *– Precast Slab*
Astoria Boulevard Station

1.03 – MR 003 | 30th Avenue Station

__Summary:__ 30th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).

Description

30th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-0", narrowing to 8'-2" at the south ends. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies. Column faces measure 3'-0" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

Figure 1 *– Overall view*
30th Avenue Station

Figure 2 *– Precast concrete platforms*
30th Avenue Station

1.04 – MR 004 | Broadway Station

Summary: *Broadway Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

Broadway Station is an elevated station with two straight side platforms. The platform structures are precast concrete. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies the canopies cover approximately half of the platforms.

NOTE: Station specific dimensions and photographs could not be obtained at the time of this report due to station closure for rehabilitation.

1.05 – MR 005 | 36th Avenue Station

Summary: *36th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

36th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-0. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies. Column faces measure 4'-0" from their adjacent platform edges throughout. The canopies cover approximately half of the platforms. See figure 1 & 2 for reference.

***Figure 1** – Overall view*
36th Avenue Station

***Figure 2** – Precast concrete platforms*
36th Avenue Station

1.06 – MR 006 | 39th Avenue Station

Summary: *39th Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 1).*

Description

39th Avenue Station is an elevated station with two straight side platforms. The platform structures are precast concrete. There are two staircases at the center of each platform. The platforms are straight with a single row of columns supporting their respective station canopies the canopies cover approximately half of the platforms.

NOTE: Station specific dimensions and photographs could not be obtained at the time of this report due to station closure for rehabilitation.

1.07 – MR 007 | Lexington Avenue / 59th Street Station

Summary: *Lexington Avenue / 59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at all obstructions as the remaining width would be 30" (see figure 1).*

Description

Lexington Avenue / 59th Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 20'-0" throughout. Columns are spaced 15' on center with column faces 4'-0" away from the platform edges. The walls at the end of platform are 45" from the platform edge. The implementation of a platform edge barrier would reduce this width to 30" or less* which would not allow for ADA compliant wheelchair movement. Please see **figure 1** for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Lexington 59th Street Station

1.08 – MR 008 | Fifth Avenue / 59th Street Station

Summary *Fifth Avenue / 59th Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at the center of each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey.*

Description

Fifth Avenue / 59th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound platform width is approximately 11'-10" throughout. The northbound platform width is approximately 11'-6" throughout. At the center of each platform there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs. **(see Figure 3)**

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located at the west mezzanine flush to the wall (see **Figure 1, Figure 2**). The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

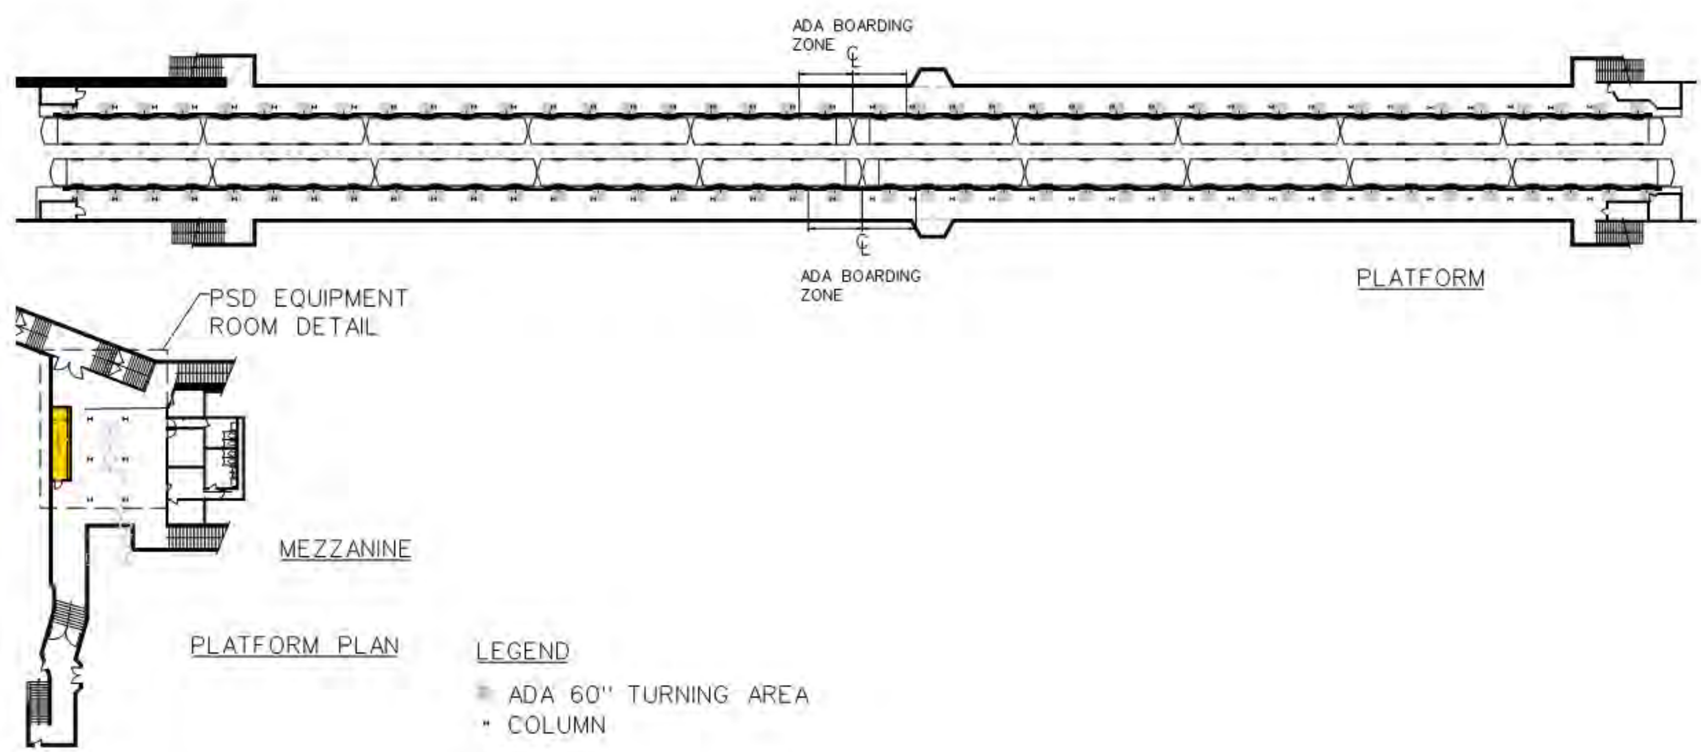

***Figure 1** – Overall Station Plan*
Fifth Avenue Station

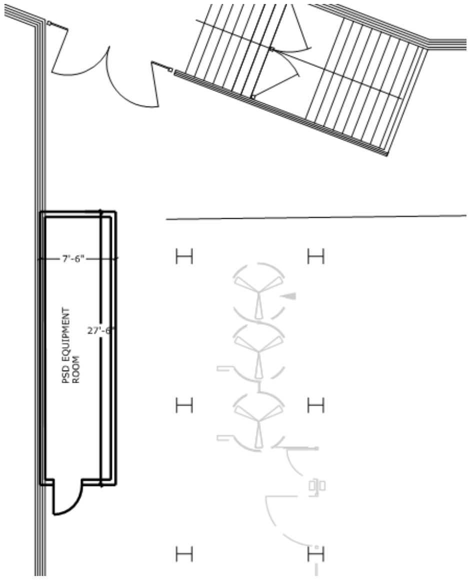

Figure 2 *– PSD Equipment Room Detail*
Fifth Avenue Station

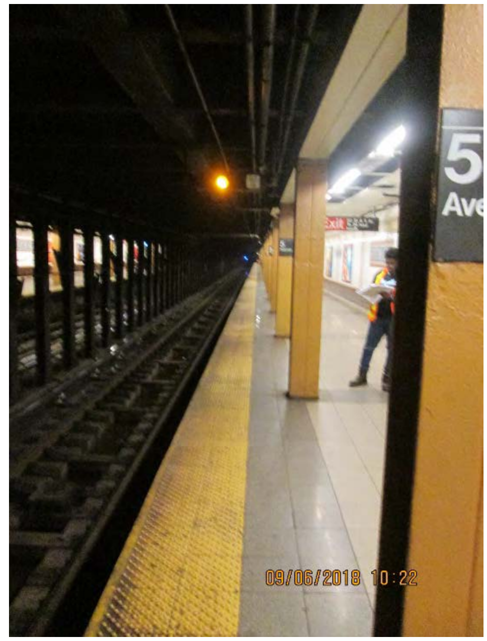

Figure 3 *– Signal above platform edge*
Fifth Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.2M to install APGs and $40.0M to install PSDs (See Appendix E)

Figure 4 *– Typical Platform View*
Fifth Avenue Station

1.09 – MR 009 | 57th Street 7th Avenue Station

Summary: *57th Street 7th Avenue is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the center stairs as the remaining width would be 27" (see figure 1).*

Description

The 57th Street Station is an underground station consisting of two center / island platforms. The platforms are approximately 19'-8" wide. The platforms are straight with two rows of columns at 42" from the edge of the platform. At four staircases columns flank the stair. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA dimension*
57th Street Station

1.10 – MR 010 | 49th Street Station

Summary: *49th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The 49th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns on the platforms. The platform width varies from approximately 7'-0" to 14'-8". On the southbound platform there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-6". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located as a split room, with one at the south control area of the southbound, and one located at the north control area of the southbound. (see **Figure 1, Figure 2**). The proposed room dimension are 16'-0" x 7'-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

Reconstruction of the concrete platform edge will be required for the installation of an APG system due to the current platform edge condition rating. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

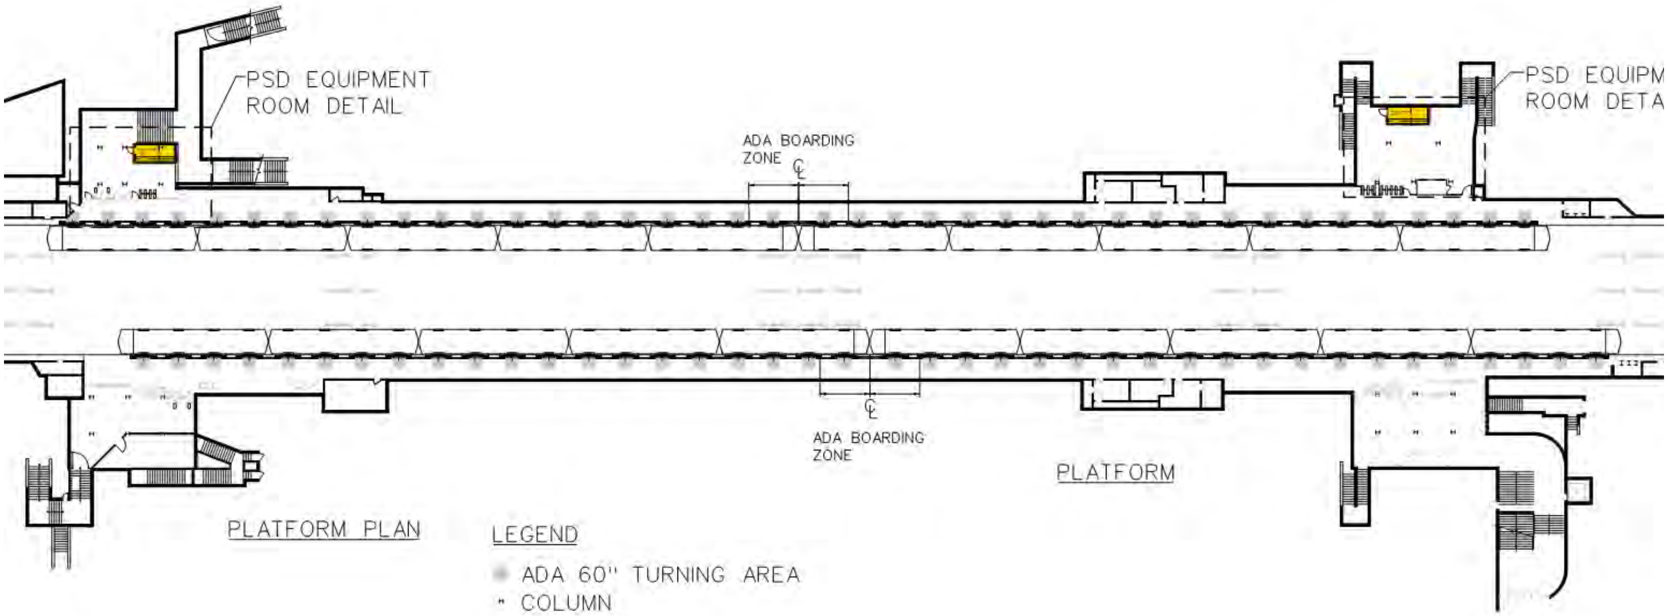

***Figure 1** – Overall plan*
49th Street Station

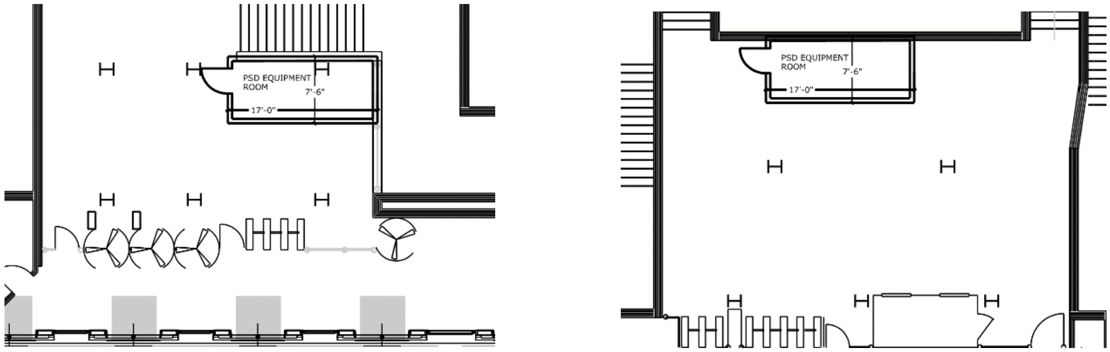

Figure 2 *– PSD Equipment Room Detail*
49th Street Station

Platform obstructions within 5' of edge:

None

Lighting:

Existing lighting: Throughout both platforms; linear fluorescent; perpendicular to the platform edge mounted in the ceiling coffers. No lighting reconfiguration will be required as part of a PSD installation.

Figure 3 *– General platform view*
49th Street Station

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis

Station Name	49th Street
Peak Demand Load from ConEd Report, Last **12** Months, (kW)	45.2
Apparent Power (kVA)	56.5
Station Peak Demand Load, Max Current, (A)	156.9
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	352
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	449
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Normal service**. Meter reading is for 12 months.

**Station
Power Capacity Analysis**

Station Name	49th Street
Peak Demand Load from ConEd Report, Last 12 Months, (kW)	27.2
Apparent Power (kVA)	34.0
Station Peak Demand Load, Max Current, (A)	94.5
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6

Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service. This analysis is for **Reserve service**. Meter reading is for 12 months.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.5M to install APGs and $43.5M to install PSDs (See Appendix E)

1.11 – MR 011 | Times Square / 42nd Street Station

Summary: *Times Square / 42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 19" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the Shuttle, 7, 1,2,3-line for the remainder of the station)*

Description

Times Square / 42nd Street Station is a below-grade station consisting of two center / island platforms. The platform width is 19-4" throughout. The platforms are straight with two rows of columns at 3'-8" from edge of platform. At the south end of the platforms, the columns flanking an equipment room are 2'-10" from the platform edge. The implementation of a platform edge barrier would reduce this width to 19" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** –platform*
42nd Street / Times Square Station

1.12 – MR 012 | 34th Street / Herald Square Station

Summary: *34th Street / Herald Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32” minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25” (see figure 1). (Note: this report covers only the Broadway BMT platforms; see the B, D, F, M-line report for the remainder of the station)*

Description

34th Street / Herald Square Station is a below-grade station consisting of two center / island platforms. The platform width is 19-8” throughout. The platforms are straight with two rows of columns at 3’-4” from edge of platform. On the center / island platform the columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 25” or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *–platform*
34th Street Station

1.13 – MR 013 | 28th Street Station

Summary: *28th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

28th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-6" from the platform edge at each platform, though approximately one third of the platform is column-free. The platform width varies from 6'-0" to 9'-5. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2, below, shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar..

.

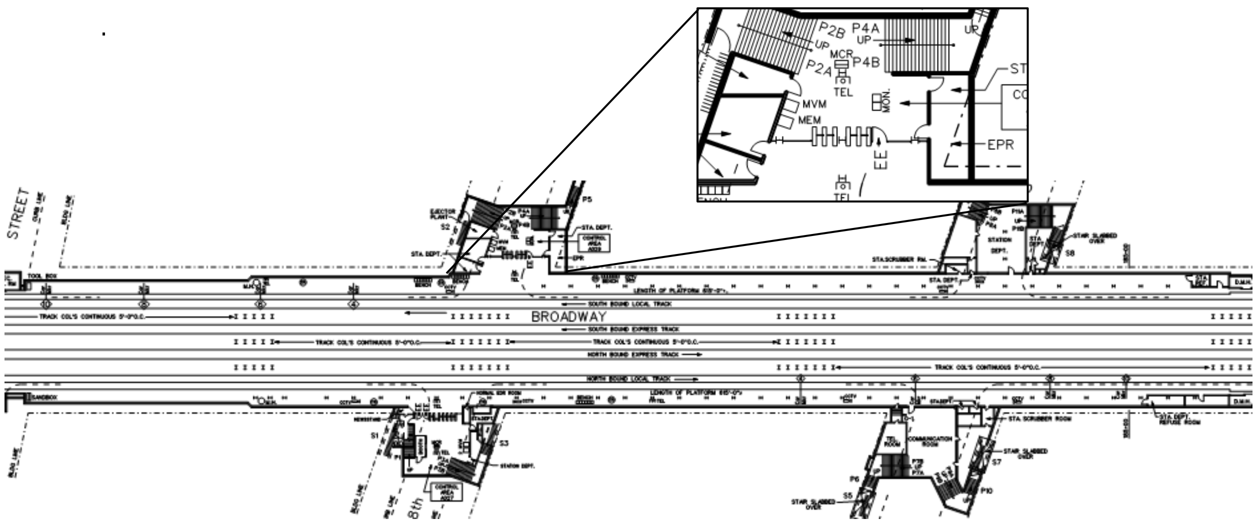

***Figure 1** – Station Plan- 28th Street Station*

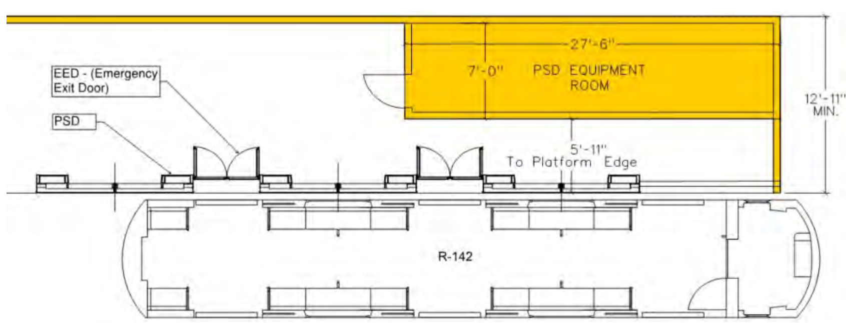

***Figure 2** – Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimensions)

1.14 – MR 014 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound platform control area as the remaining width would be 27" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-8" from the platform edge at each platform. The platform width varies from 6'-0" to 11'-2" in width. The entry / exit turnstiles at the south entrance of the northbound platform are positioned with minimal clearance of 18" to the adjacent columns. The remaining space between the columns and the platform edge measures 42". The implementation of a platform edge barrier would reduce this width to 27" which would not allow for ADA compliant wheelchair movement. See figures 1and 2 below. The plan in figure 1 demonstrates that there is no alternative location for the turnstiles / railings.

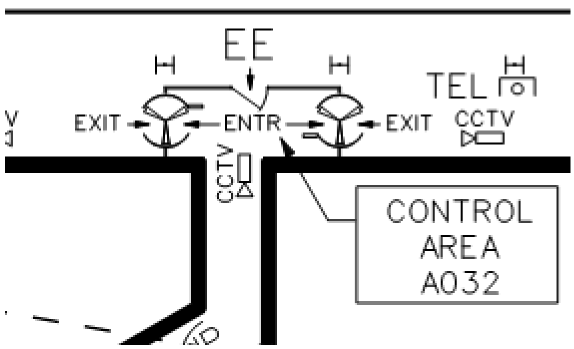

***Figure 1** – Non-Compliant ADA condition - 23rd Street*

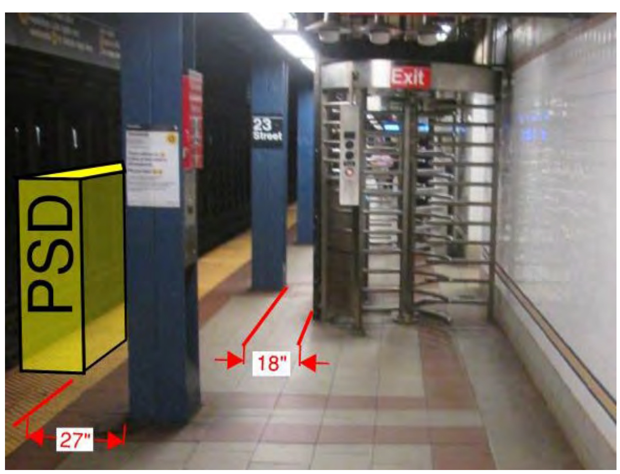

***Figure 2** – Non-Compliant ADA condition - 23rd Street*

1.15 – MR 015 | 14th Street / Union Square Station

Summary: *14th Street / Union Square Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1). (Note: this report covers only the Broadway BMT platforms; see reports for the L-line and 4,5,6-line for the remainder of this complex)*

Description

14th Street / Union Square Station is a below-grade station consisting of two center / island platforms. The platform width is 18-8" throughout. The platforms are straight with two rows of columns at 3'-6" from edge of platform; these columns flank multiple staircases. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
14th Street / Union Square

1.16 – MR 016 | 8th Street Station

Summary: *8th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

8th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns 3'-4" from the platform edge at each platform. The platform width varies from 9'-6" to 11'-0" in width. The south street stair at each platform is positioned with minimal clearance to the adjacent columns. The remaining space between the columns and the platform edge measures 40". The implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
8th Street Station

1.17 – MR 017 | Prince Street Station

Summary: *Prince Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

Prince Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-6' to 8'-8". Platform width at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width to 21" or less below the required minimum of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Prince Street

1.18 – MR 018 | Canal Street Station

Summary: *Canal Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 33" (see figure 1). (Note: this report examines only the upper platforms at this station. See the N-line report for the lower platforms)*

Description

Canal Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 7'-0' to 11'-8". Platform width at the south end of the northbound platform is 48". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Canal Street Station

1.19 – MR 020 | City Hall Station

Summary: *City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see figure 1).*

Description

City Hall Station is a below-grade station with a center / island platform. The platform structure is cast-in-place concrete. The platform width varies from 23'-8" to 46'-4". There are four lines of columns, with those adjacent to the track being 3'-4" from the platform edge. Ceiling heights measure no less than 7'-6" throughout. At the stair to the lower level, clearance along the platform edge is constricted by columns subdividing the space into two narrow widths. The available 40" width between columns and platform edge will be further constricted by the introduction of PSDs, reducing the width to 25" or less* which would not allow for ADA compliant wheelchair movement. See Figure 1 below.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
City Hall Station

1.20 – MR 021 | Cortlandt Street Station

Summary: *Cortlandt Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-3"" (see figure 1).*

Description

Cortlandt Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-3' to 19'-8". There are two ceiling-mounted signals at each platform at a minimum 6'-11" clearance.

Platform width at the south end of the northbound platform is 5'-3". With the installation of PSDs, this dimension will be reduced to 48" *. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress via emergency exit doors with an installed PSD system. See figure 1 for reference.

*Please note that the egress clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant code condition*
Cortlandt Street Station

1.21 – MR 022 | Rector Street Station

Summary: *Rector Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the northbound control area as the remaining width would be 25" (see figure 1).*

Description

Rector Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 10'-2' to 11'-8". At the turnstile line on the northbound platform, clearance between the turnstiles and the row of columns is only 20". At this area there is 40" between the columns and the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum of 32" for a pinch point. The remaining 25" would not allow for ADA compliant wheelchair movement. See figure 1 for reference. The plan of this area shown in Figure 2 reveals the constrained conditions within the unpaid area and demonstrates that there is no available space for reconfiguration of turnstiles to ameliorate the non-compliant conditions.

***Figure 1** – Non-Compliant code condition*
Rector Street Station

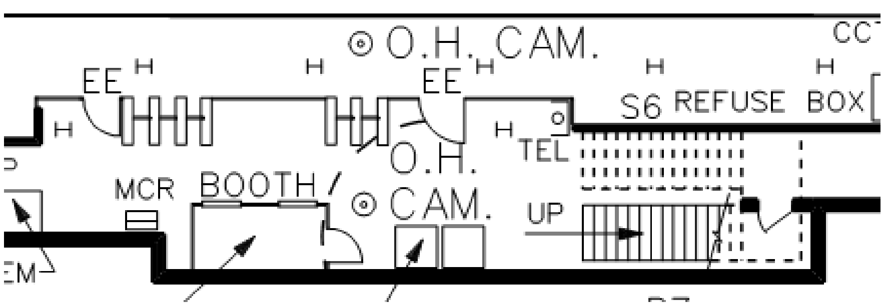

***Figure 2** – Constrained control area; northbound platform*
Rector Street Station

1.22 – MR 023 | Whitehall Street Station

Summary: *Whitehall Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 21" (see figure 1).*

Description

Whitehall Street Station is an underground station consisting two center / island platforms. The platforms are approximately 12'-6" wide throughout. At four staircases, columns flank the stair, leaving a dimension of 36" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 21" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
Whitehall Street Station

1.23 – MR 461 | Queensboro Plaza Station

Summary: *Queensboro Plaza Station is feasible for APGs only. The "7", "N" and "W" trains are served on both the upper & lower levels, with the 7 train and N/W trains on opposite sides of the center / island platforms. The No. 7 sides of these platforms are the subject of a separate station report. Full height PSDs are infeasible due to low beams above the platform edge at the upper level platform. Platform edge reconstruction will be required to support an APG system (see Appendix B). Existing power is adequate.*

Description

Queensboro Plaza Station is elevated with two straight center / island platforms stacked on top of each other. See figure 1 for an overall station plan. Both platforms are made of cast-in-place concrete. On the southbound platform, columns are spaced 48' on center with column faces 4'-8" from the platform edge. On the lower platform, columns are spaced 24' on center with column faces 2'-2" from the platform edge. Both platforms are approximately 19'-6" wide. On the lower platform, there is a vertical clearance of approximately 8'-0", which reduces to 7'-2" at the east-end of the platform. On the upper platform, there is a vertical clearance of approximately of 7'-2" to canopy beams at the platform edge.

Full Height PSDs: Full height PSDs are infeasible due to the low beams of the canopy at the upper level platform. The bottom of the existing beams are at 7'-10", whereas PSD manufacturers require 8'-6" of height.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall mounted conduits below the upper and lower platform edge would need to be relocated to accommodate the requirements of the APG system. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated at the eastern end of the upper platform. The proposed room would measure approximately 27' x 7'-6" (see figure 2). As there are four platform edges at this station (including the No. 7 train), two equipment rooms would be needed to accommodate all of the required equipment. An additional room can be located in a similar location on the lower platform.

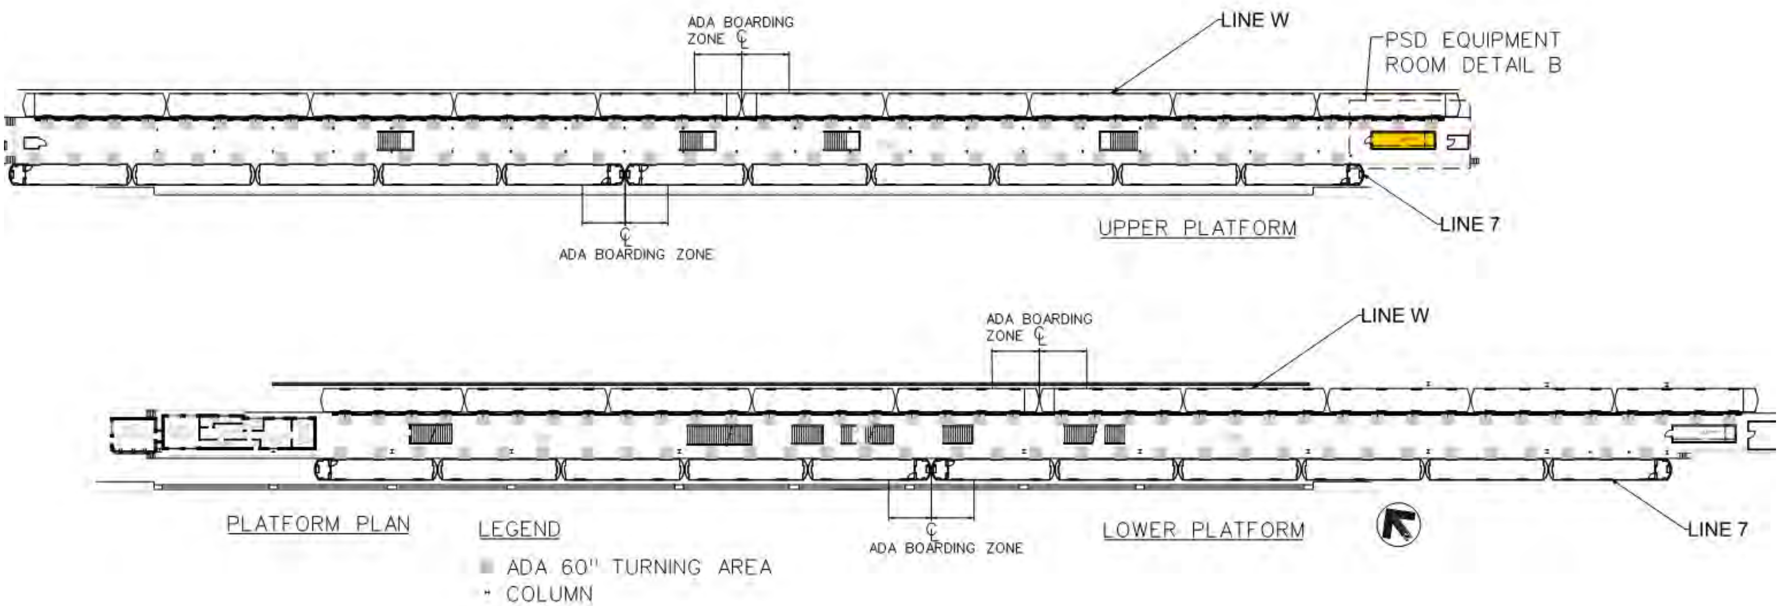

Figure 1 *– Platform plans*
Queensboro Plaza Station

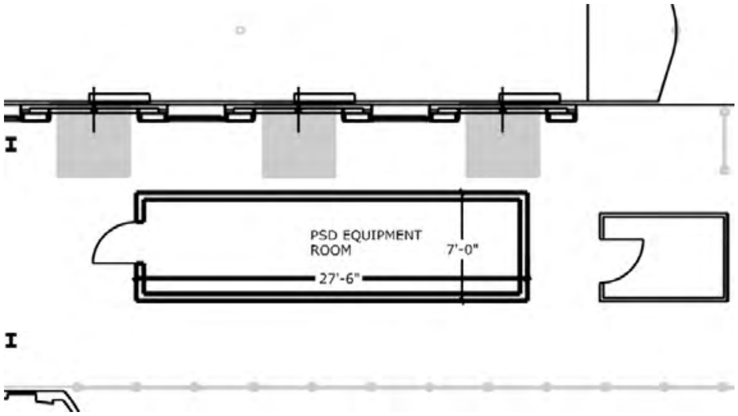

***Figure 1** – Equipment Room detail*
Queensboro Plaza Station

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, platform edge reconstruction would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.6. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

- Southbound (lower) platform:
  - All columns are 26" from the Hudson Yards platform edge.
- Northbound (upper) platform:
  - All columns are 51" from the platform edge.

These obstructions do not present an impediment to the installation of PSDs.

.

Lighting:

Existing lighting: Linear fluorescent; approximately 1' from platform edge for southbound and centered under canopy on the northbound platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity (only from the Normal service) to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Below in Table 1 please see the Power Capacity Analysis for this station.

**Station
Power Capacity Analysis**

Station Name	Queensboro Plaza
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	118.4

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.1M to install APGs. (See Appendix E)

Appendices: Table of Contents

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		PSDs	APGs	RPSDs	Grading system
General Factors	Specific Subfactors				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	Comments
Platform Screen Doors (PSDs) (> 8’ in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

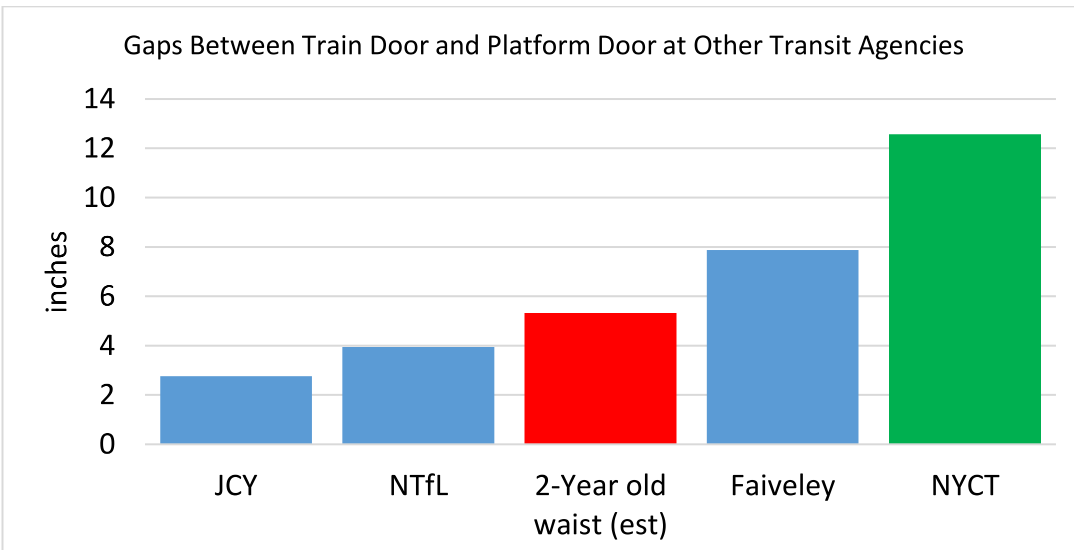

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

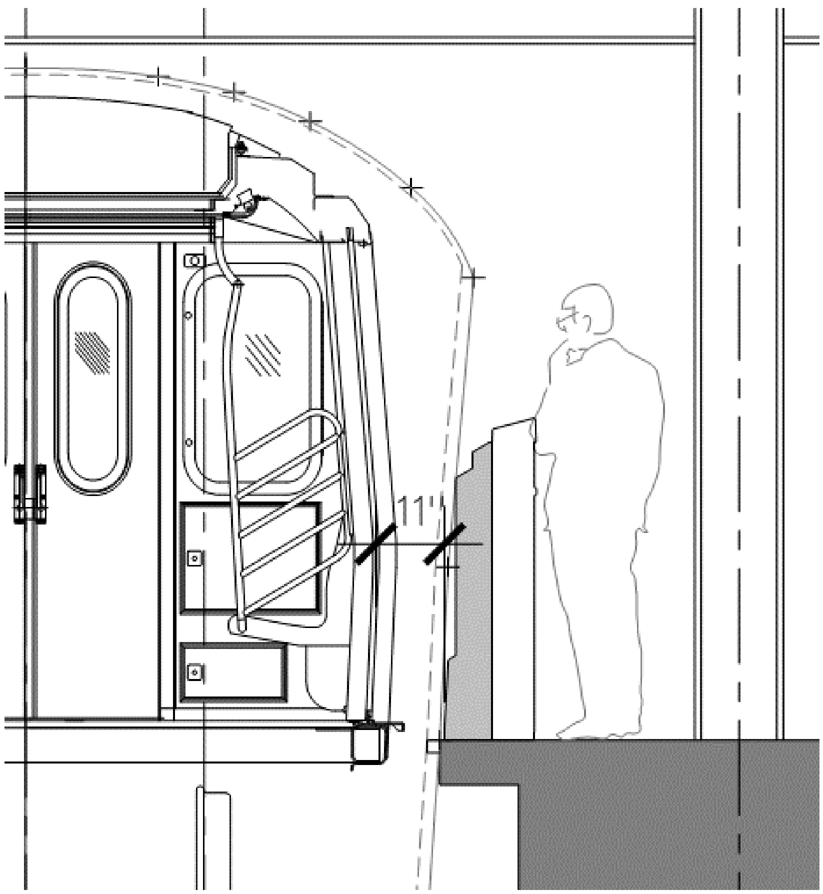

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	**3rd Ave.**	**6th Ave.**	**14 St / Union Square**	**1st Ave.**
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

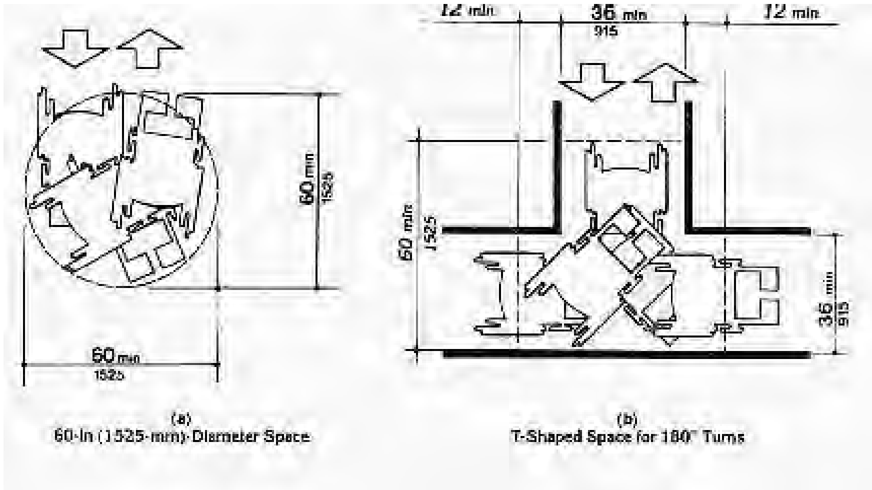
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36” which may be constricted to 32” at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

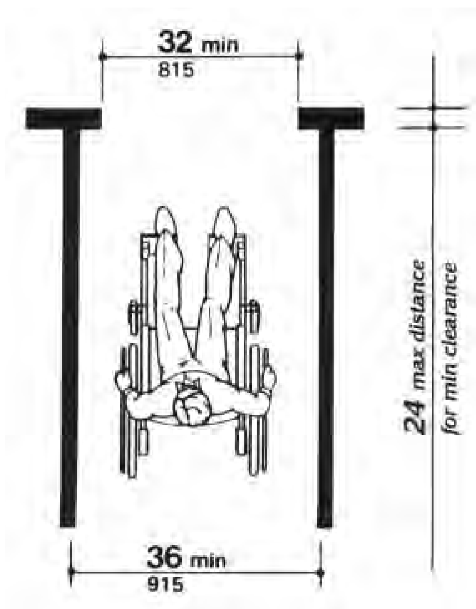


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

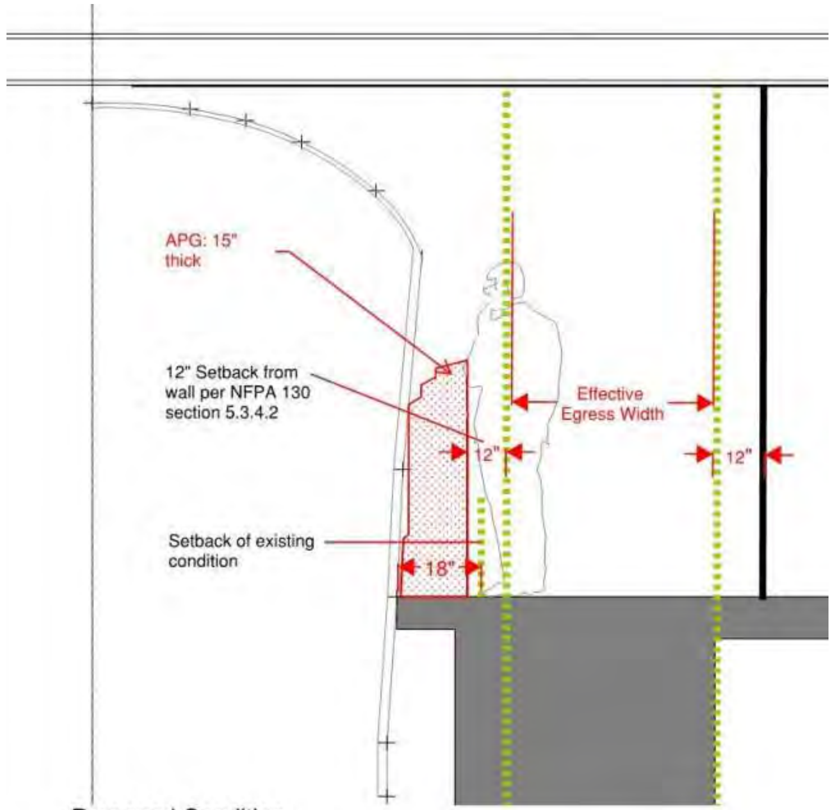
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.

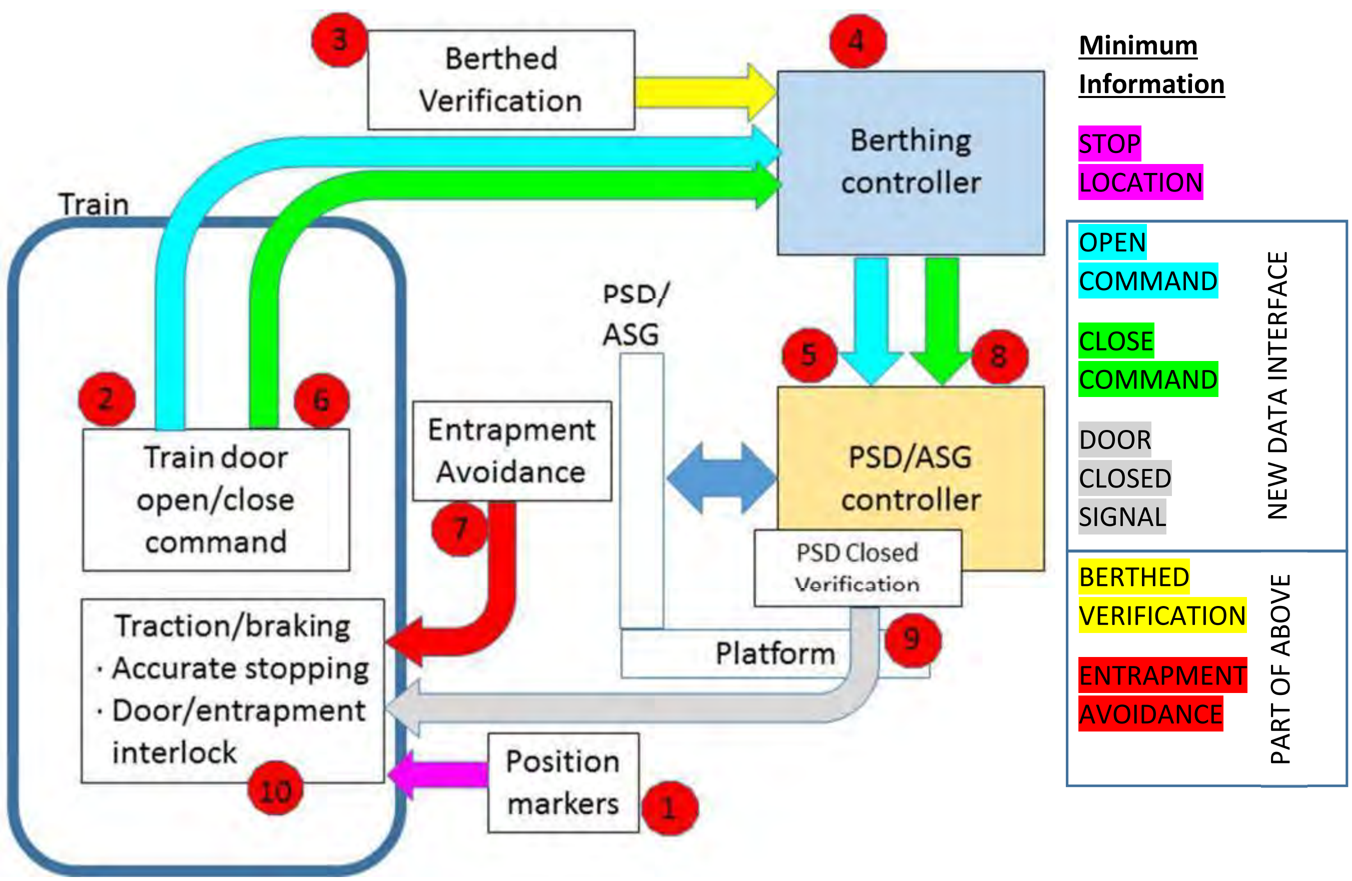

Table of Contents

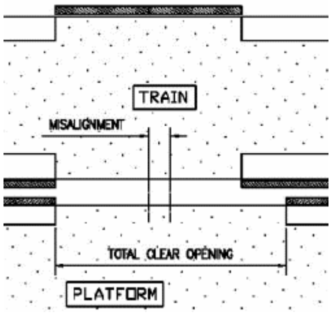
Appendix Table of Contents

Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

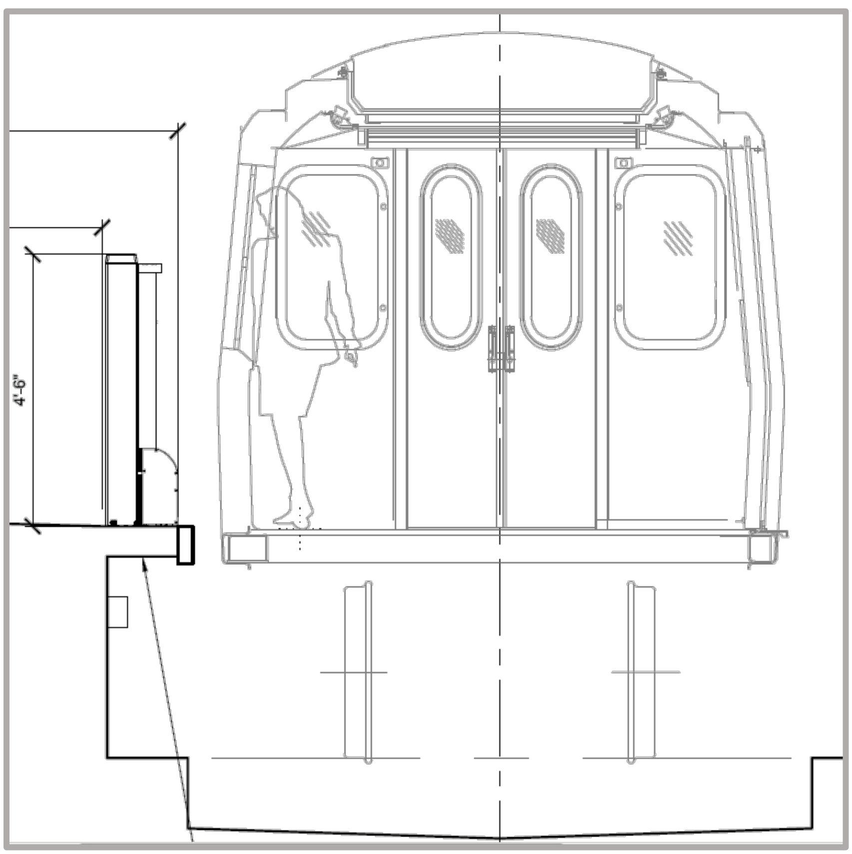


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the “wind” load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers’ requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1” thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

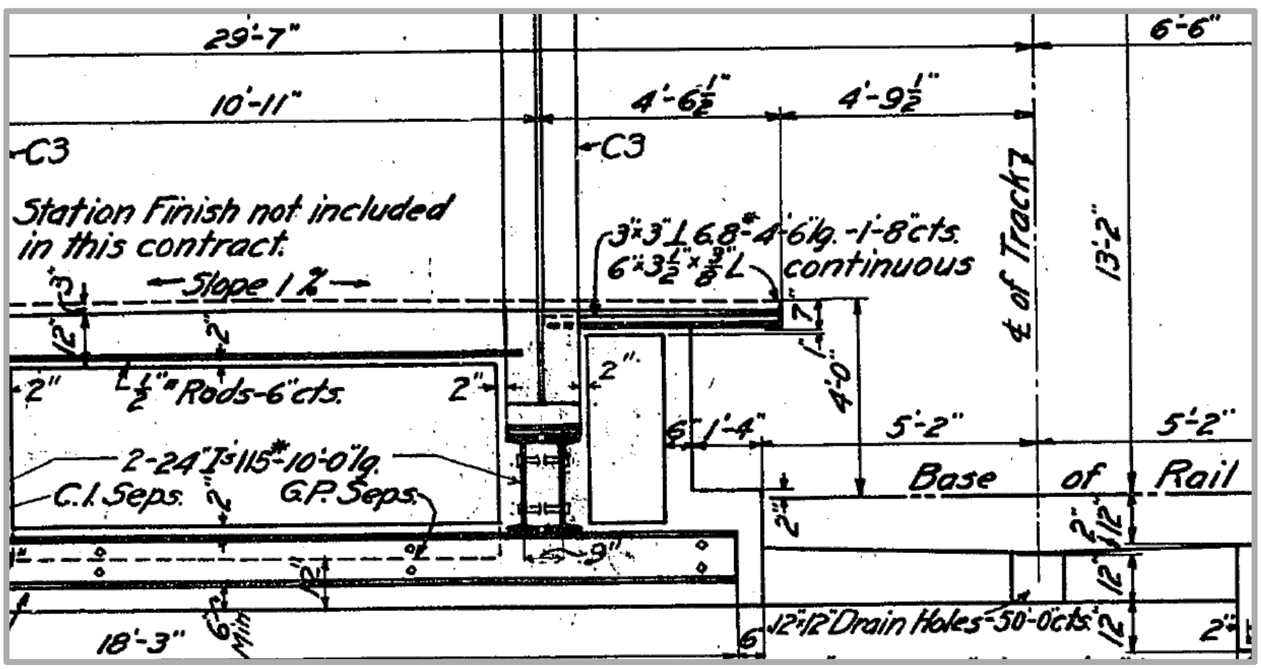

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

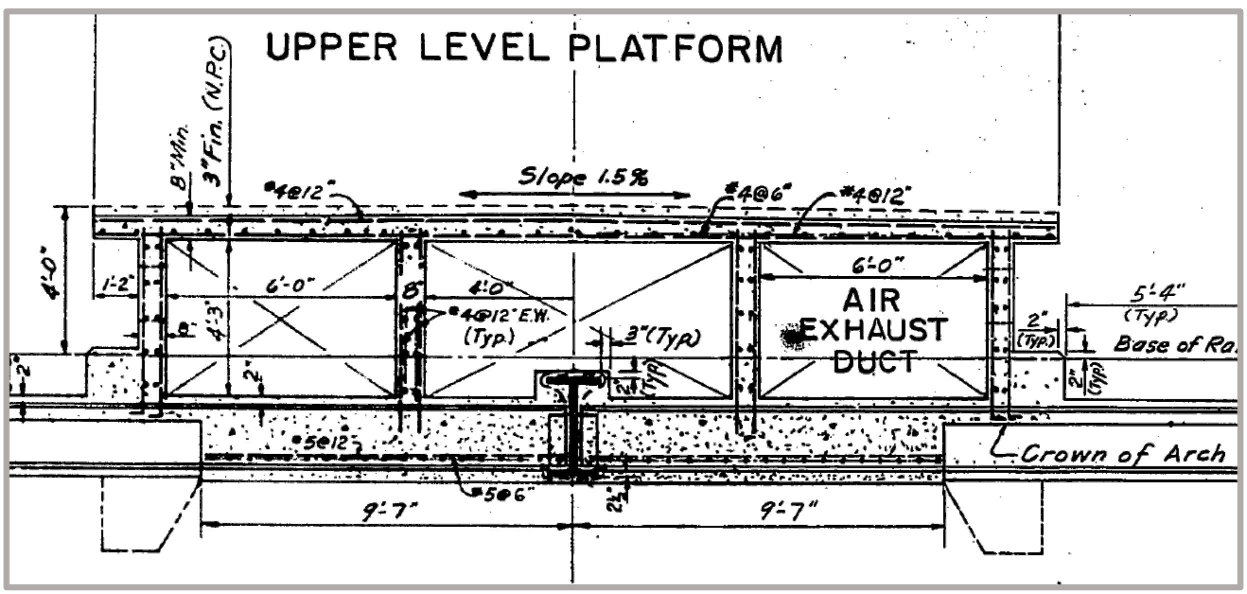

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

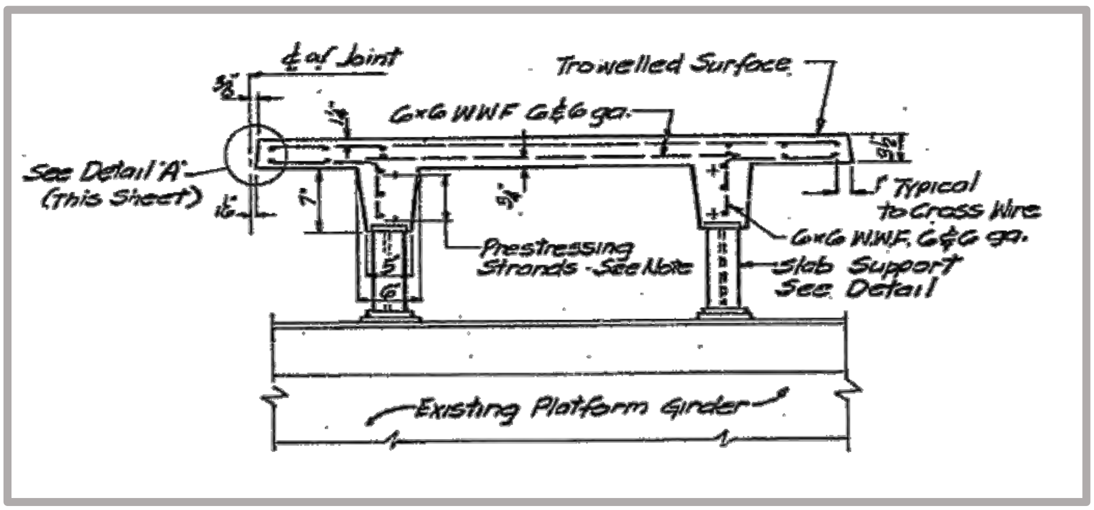

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

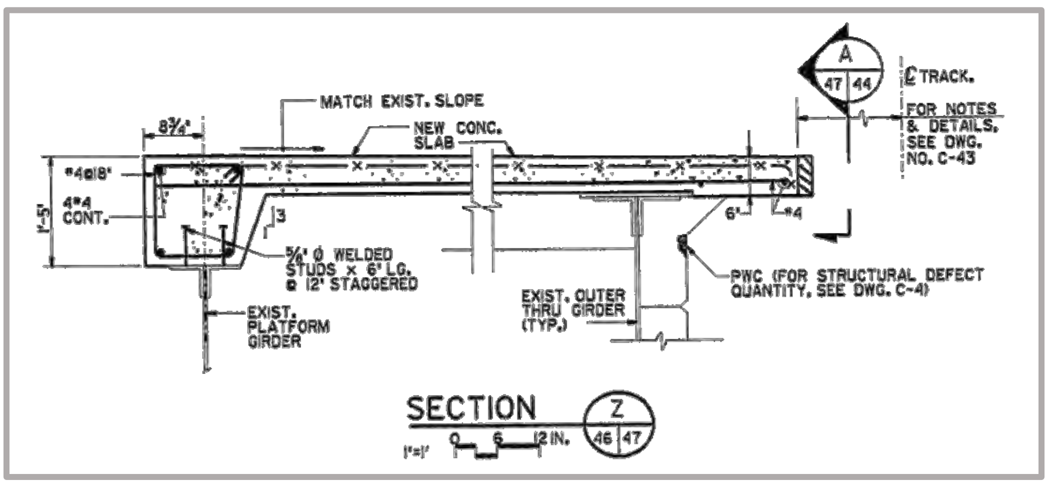

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

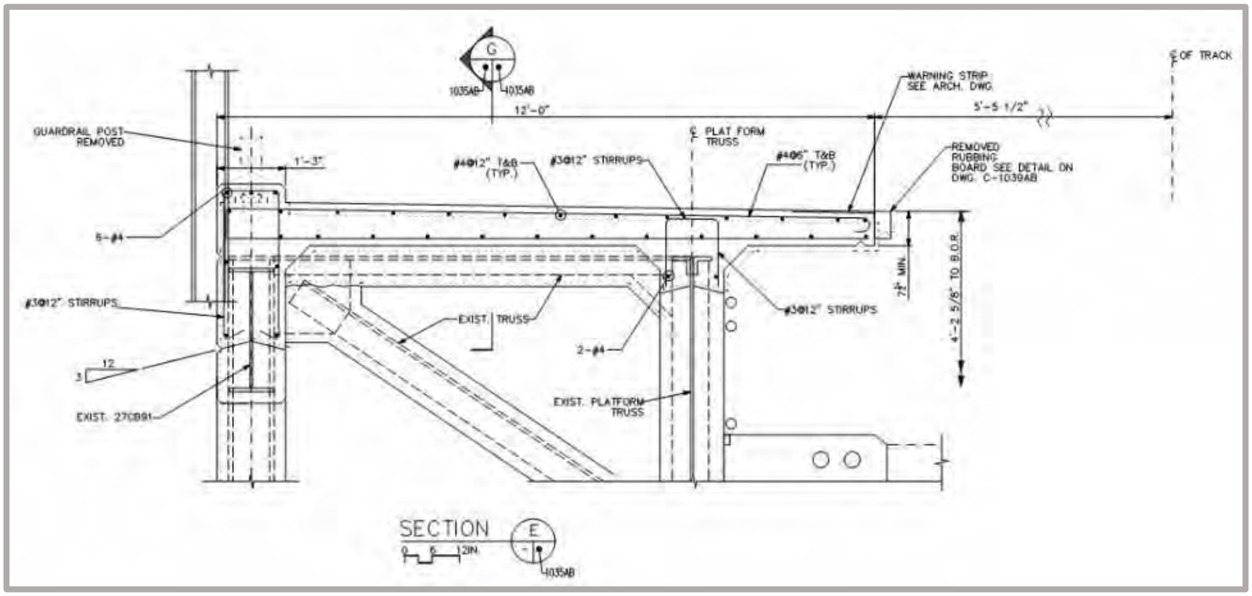

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

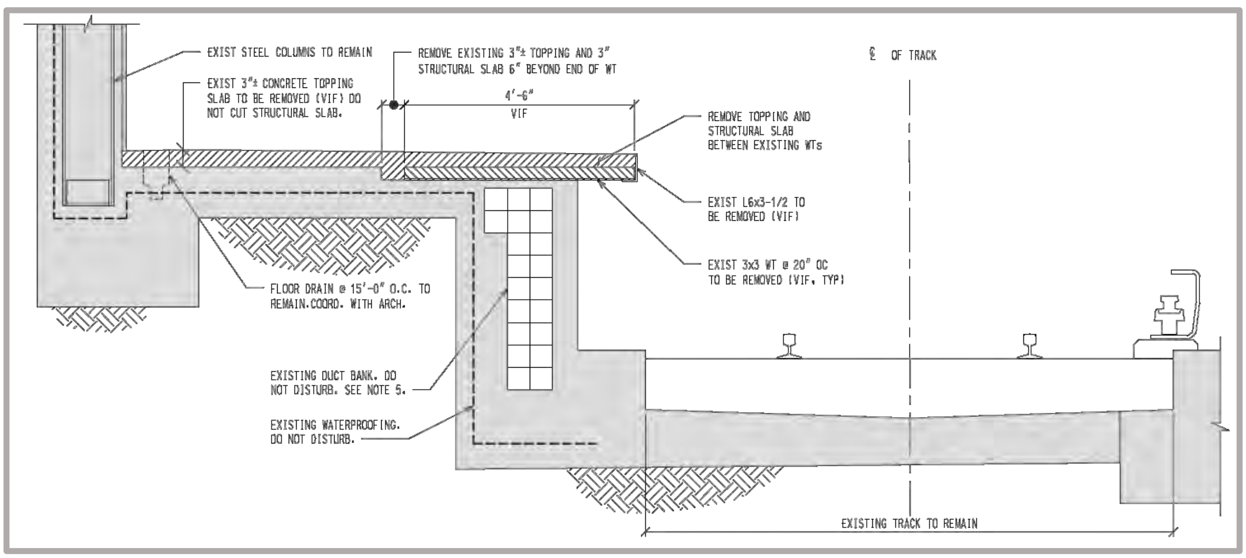

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

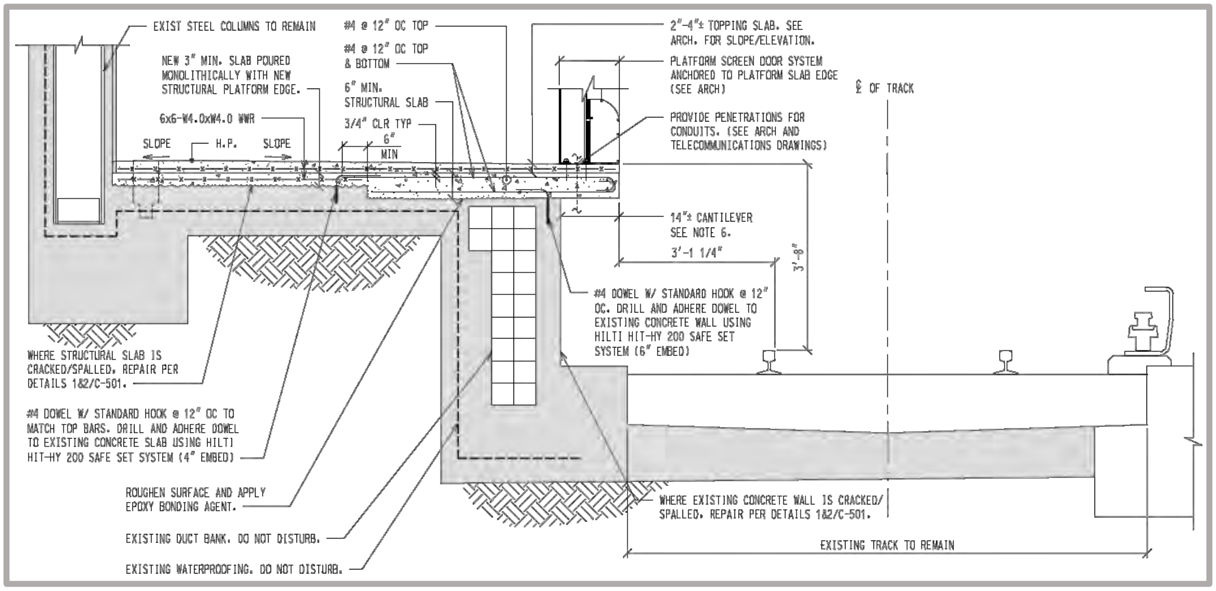

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

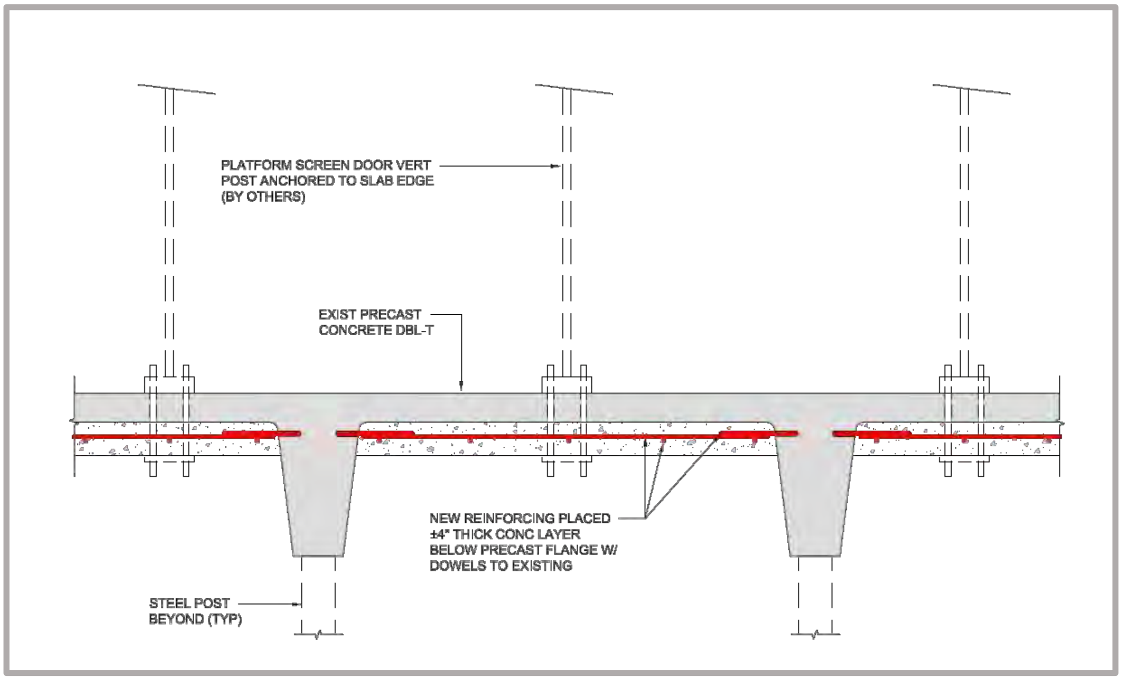

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for W - Line Stations

MTA/NYCT

January 7, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 39 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10” x 10” H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for W - Line Stations

MTA/NYCT

January 7, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for W - Line Stations

7-Jan-19

STATION : QUEENSBORO PLAZA

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE UPPER PLATFORM EDGE=	622	LF		
5	LENGTH OF THE LOWER PLATFORM EDGE =	684	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,306**	**LF**		
7	NUMBER OF TRAIN CARS ON W TRAIN TRACK =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,306	LF	7	9,142
14	Remove 5' wide section of 3" deep structural slab to platform edge	6,530	SF	12	78,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	132	CY	2,500	330,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,308	EA	25	32,700
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,308	EA	25	32,700
19	Cast in assemblies for PSD holding down bolts	320	EA	180	57,600
20	Polyethylene edge strip	1,306	LF	95	124,070
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,306	LF	15	19,590
26	Remove existing platform tiles	1,306	LF	12	15,672
27	Sawcut existing topping concrete at perimeter of removal area	1,306	LF	5	6,530
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,836	SF	8	62,688
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,306	SF	15	19,590

Tier 2-3 Report on Feasibility of Platform Edge Barriers for W - Line Stations

7-Jan-19

STATION : 49TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	703	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	703	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,406**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,406	LF	7	9,842
14	Remove 5' wide section of 3" deep structural slab to platform edge	7,030	SF	12	84,360
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	142	CY	2,500	355,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,408	EA	25	35,200
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,408	EA	25	35,200
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,406	LF	95	133,570
21	Provide sleeves for HV & LV wires	328	EA	110	36,080
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,406	LF	15	21,090
26	Remove existing platform tiles	1,406	LF	12	16,872
27	Sawcut existing topping concrete at perimeter of removal area	1,406	LF	5	7,030
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	8,436	SF	8	67,488
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	320	SF	8	2,560
30	New Work				
31	New concrete topping to match existing	1,406	SF	15	21,090

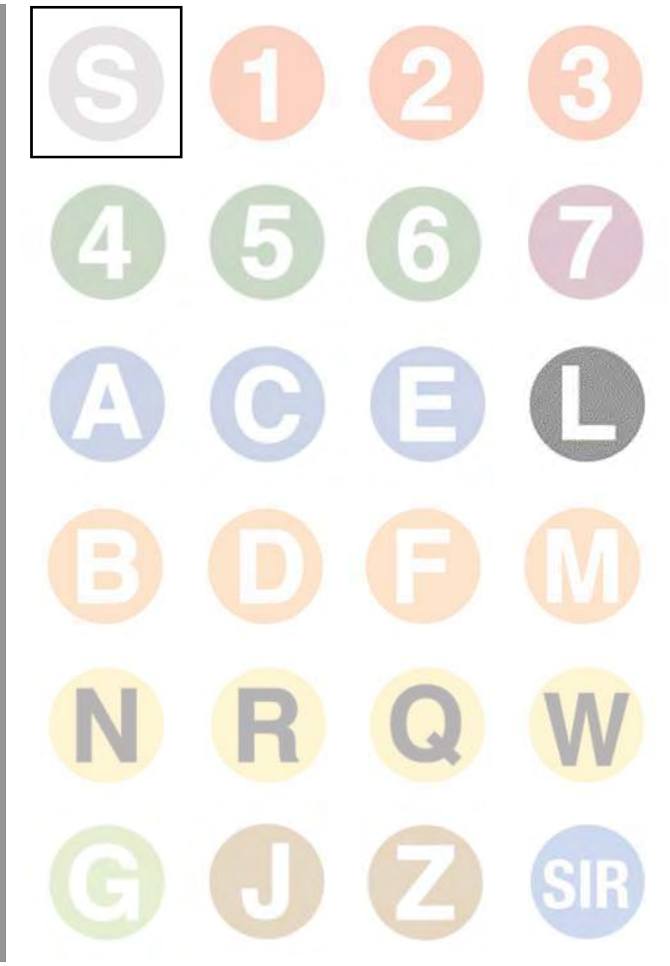
New York City Transit



REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'S' LINE STATIONS IN MANHATTAN

April 30, 2018

STV 100 Years

Table of Contents

Report on Feasibility of Platform Edge Barriers at 42nd Street Shuttle Stations (MR-468 and MR-469)

Introduction: In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility study which done to identify a location for a pilot installation of half height Platform Screen Doors (PSD) at a revenue station. That study was published in August 2017. A summary of the technology section of that report (section 1.0 through 5.0) is included in Appendix A of this report for reference. It generically analyzes issues of platform edge technology, operations issues, and code in regard to the installation of platform edge barriers across the NYCT system. Section 6 of that report looked at the impact of this new technology on four stations on the Canarsie line in Manhattan. This report continues the station analysis with section 1.0 pertaining to the two platforms, Times Square Station and Grand Central Station, serving each end of the 42nd Street Shuttle Line.

In the hierarchy of our system-wide study, this is a Tier 2/3 report. The Tier 1 analysis of door arrangement in the vehicles dedicated to this line found that there are no problems of incompatibility; One train car type and one train consist will be run in the future 2-track, 6-car train scenario on the Times Square / Grand Central Shuttle. Our analysis is based upon design drawings for contract A-35301 / 37116 for the reconfiguration of the Shuttle platforms (a summary extract from those drawings is included as an Appendix to this report). Those design drawings show two 6-car trains platforming on each side of a center platform at each end of the Shuttle. The train cars and consists are shown generically with no distinction between A or B cars. Based upon the car assignment update from Operations Planning (Nov 2017) we have used the R62A cars for the supporting diagrams in this study.

Following the methodology of our system-wide analysis, this Tier 2/3 report looks at issues of obstructions near the platform edge, platform edge curvature, structural feasibility, location of the equipment room, and an evaluation of available power.

Computational Fluid Dynamics (CFD) analysis is beyond the scope of this study due to the time and cost involved. Based upon CFD analyses done for the 3rd Avenue pilot installation of half height automated platform gates (APGs) this study assumes that such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.

An NFPA130 timed egress analysis for the existing stations or for potential APG/PSD designs is also beyond the scope of this study.

1.0 Station Descriptions

1.1 Grand Central Station – 'S' Shuttle Platforms

Executive Summary: *Grand Central Station is not feasible for APGs or PSDs due to the close proximity of columns to the platform edge (16") at the western end of the north platform. Contributing to this finding are other constraints including a low girder in the same area that would conflict with full height PSDs and existing stair P8 on the south platform that limits space available for APG/PSDs.*

The existing Shuttle platforms at Grand Central Station (GCS) are made up of two end-loaded platforms serving three dead ended tracks running three, four-car trains. The new design for the Shuttle fills in the center track to create a new larger center platform serving two tracks running the longer six-car trains. In order to accommodate the longer train on the northern track the project will open up an area of the platform currently used as back-of-house. An illustration of the new configuration follows on page 4 (Figure 1).

Full height PSDs: As already noted in the Executive Summary above APG/PSDs are not feasible. Were that not the case, existing lighting and conduit on the station ceiling would have to be reconfigured if full height PSDs were to be installed. In addition, full height PSDs would require lateral bracing to the roof structure.

Half Height APGs: If APGs could be installed they present a slightly simpler installation scenario. Ceiling mounted lighting would have to be reconfigured to accommodate APG entrapment prevention sensors and CCTV cameras, no other new systems would touch the ceiling.

Equipment Room

Space appears available. However, it was not studied due to infeasibility created by obstructions at the platform edge.

Track Layout

New platform configuration based on current track alignment. Southern track is tangent and the northern track is tangent with a slight curve at the west end. No excessive gaps are anticipated.

Platform edge condition

Existing conditions: Porcelain tactile tiles laid on recently rebuilt concrete cantilever. See the draft report on Structural Feasibility of Platform Barriers (Appendix B). There are currently no plans to rebuild the GCS Shuttle platform edges under contract A-35301/37116. Based upon the structural report, installation of the half-height APGs would require reconstruction of the platform edges. However, the full-height PSDs could be installed utilizing the existing concrete platform were it not for other constraints.

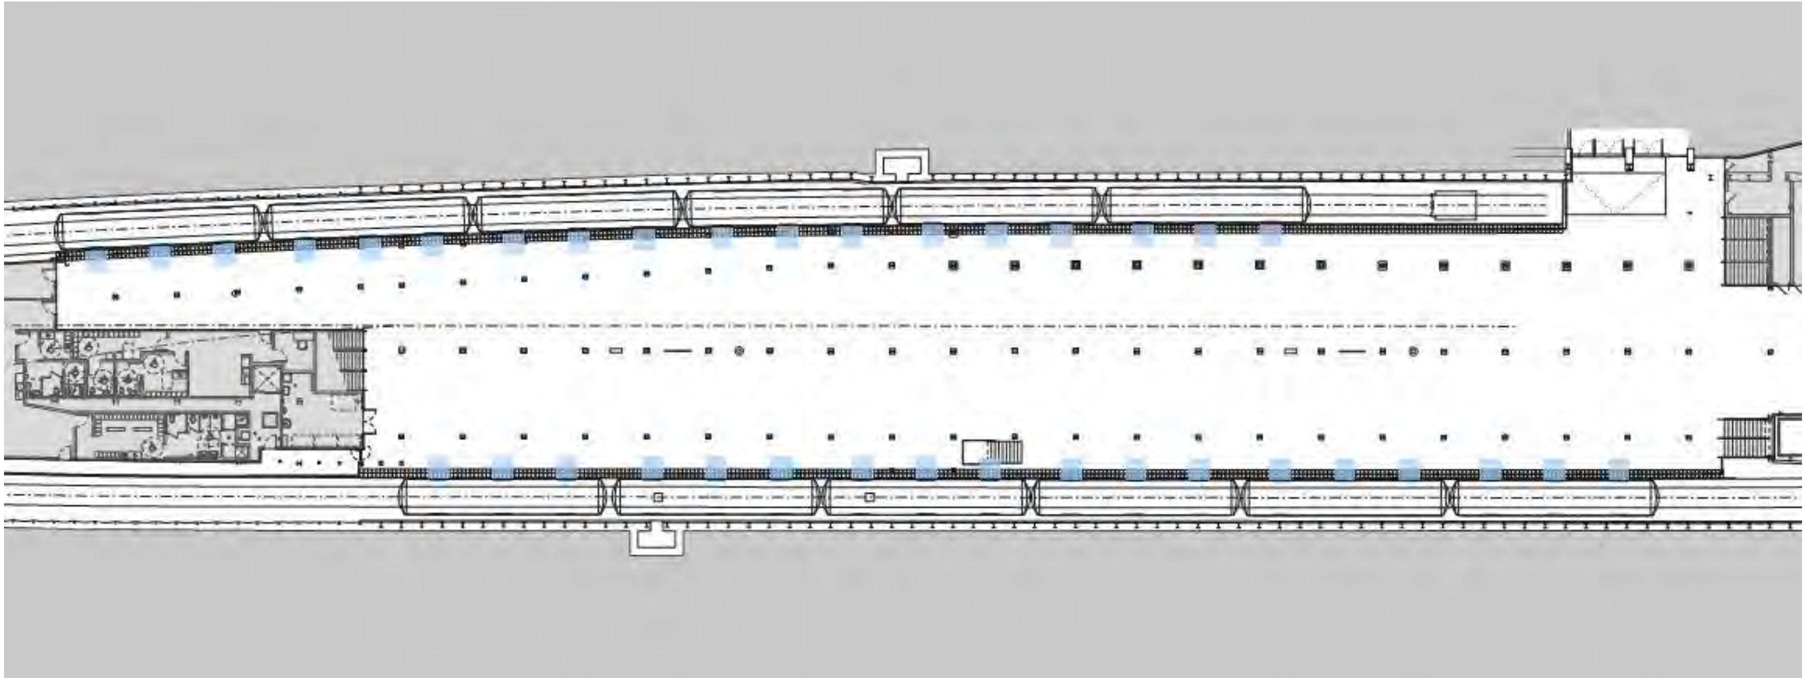


Figure 1 - Plan – Grand Central Station Shuttle overall plan (north is to the top of the plan)

Platform obstructions within 5' of edge:

Since there is some curvature at the west end of the north track in this station and because the Time Square platform at the other end of the shuttle is curved at the west end, the ADA boarding area will be located at the east end of each platform where the track is tangent. In these areas there are no obstructions within 5 feet of the platform edge.

At the western end of the North platform the existing columns are 16 inches from the platform edge. That creates a conflict at the platform edge that make half height APGs and full height PSDs impossible. Above these columns there is an existing low girder that would make installation of full height PSDs even more difficult without reframing the existing roof structure.

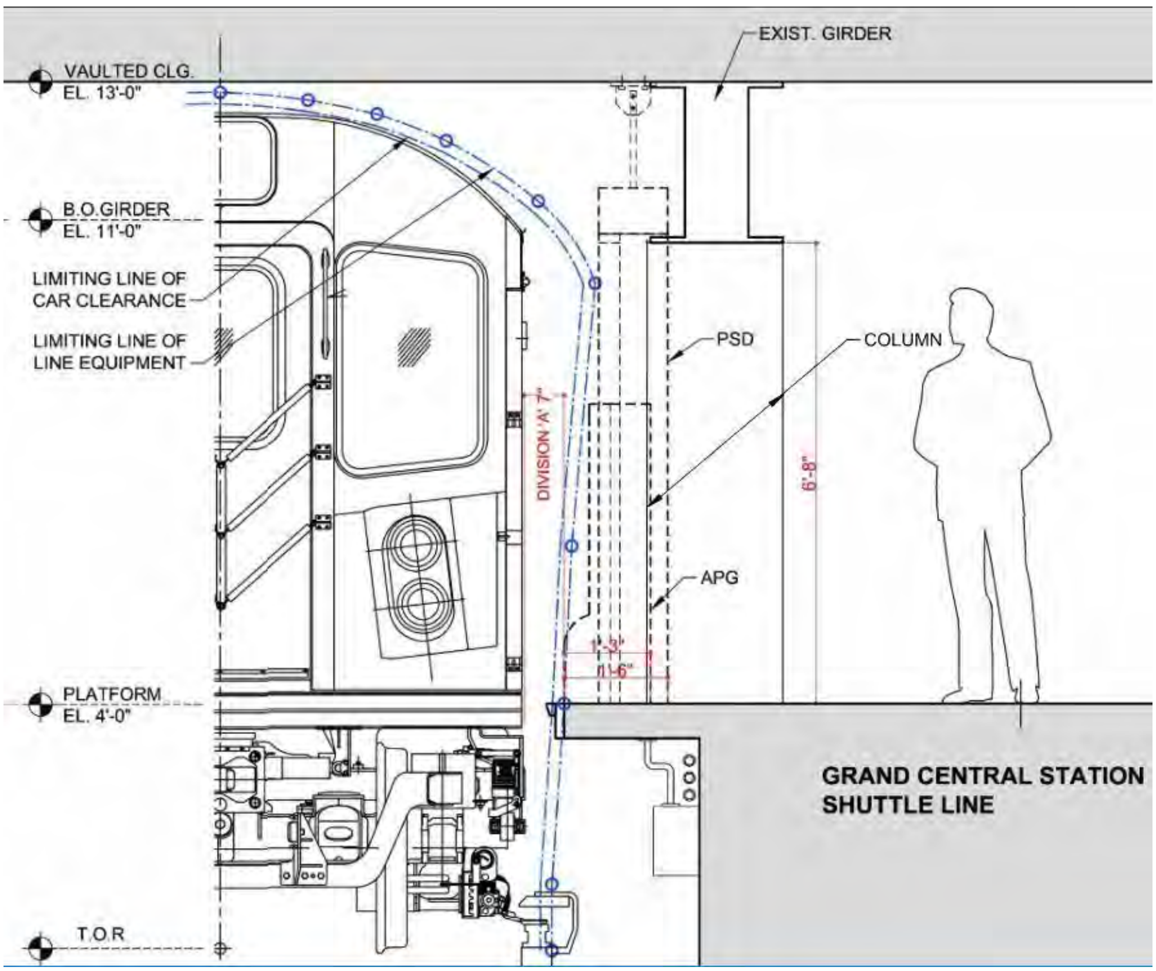

Figure 2 - Grand Central Station – Cross Section at west end of north platform showing conflict with column and beam

Figure 3 - Grand Central Station Shuttle – West end of north platform showing limited clearance for APGs or PSDs

On the South platform edge existing stair (P8) reduces space at the platform edge such that a 60" circle (ADA clearance for wheel chair turn around) does not fit. See Figure 4 below.

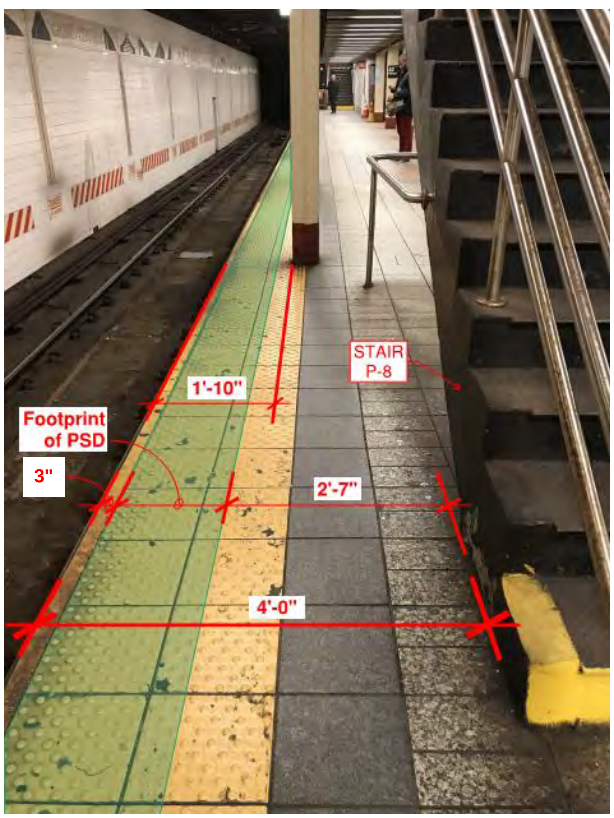

Figure 4 – Grand Central Station Shuttle – South platform detail of existing boarding clearances at Stair P8; ADA wheel chair turnaround of 60 inches does not fit

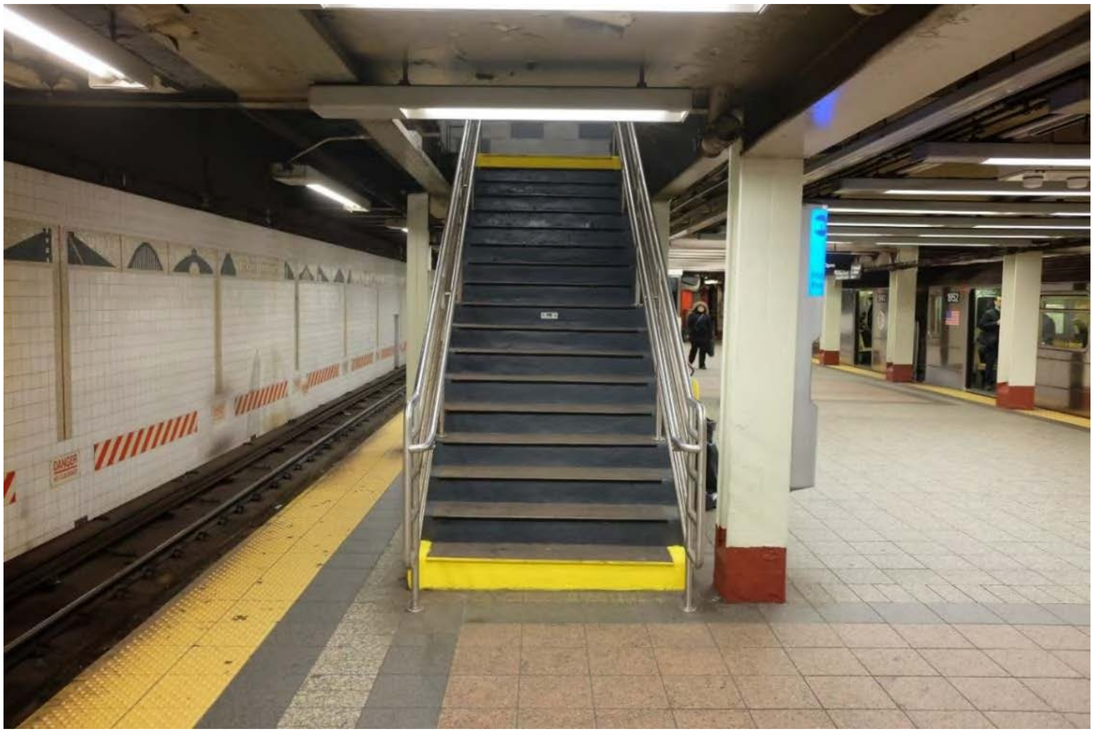

Figure 5 – Grand Central Station Shuttle – South platform photo Stair P-8

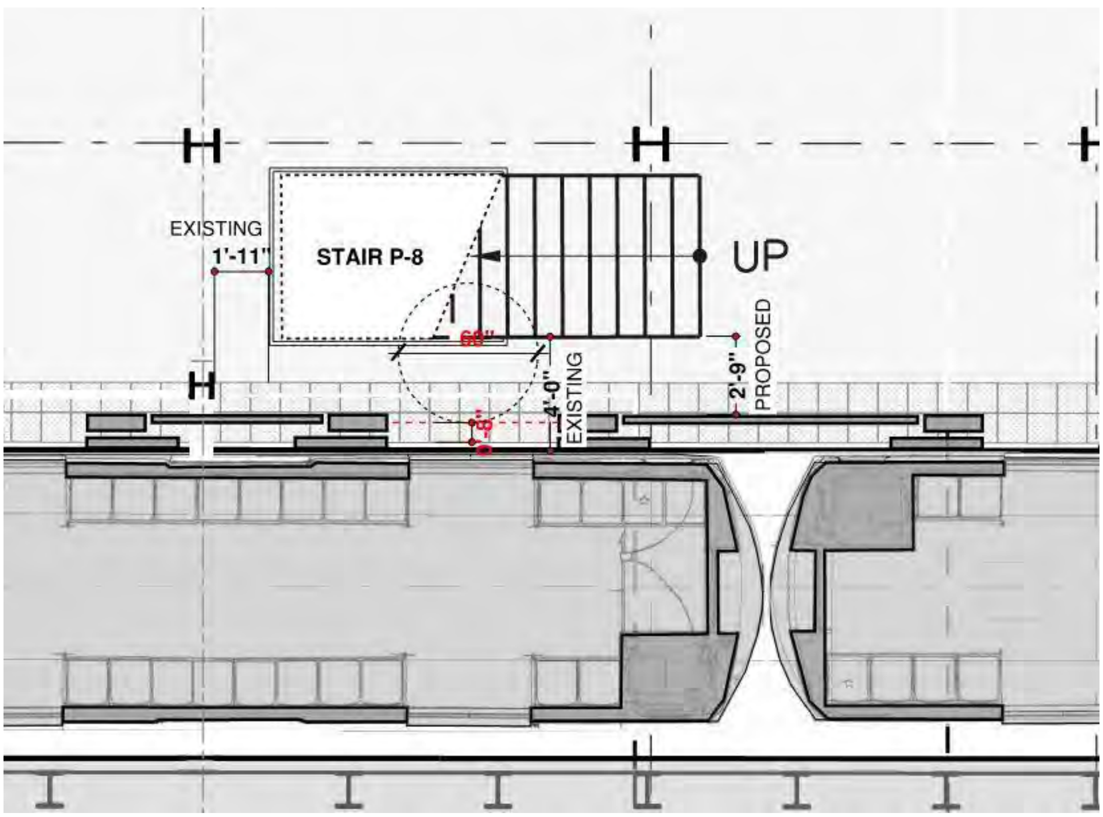

Figure 6 – Grand Central Station Shuttle – South platform plan view of existing boarding clearances at Stair P8; 60 inch circle is shown (ADA wheelchair turnaround)

Lighting:
Existing lighting: Linear fluorescent; approximately 12" from platform edge. Would not be an issue if APGs could be installed. Would require reconfiguration if PSDs were possible.

Power:
Power is adequate for either APGs or PSDs. (See Section 1.2 – Power, page 11 of this report)

Historic Restrictions:
The Shuttle at Grand Central is adjacent to historically designated property at the railroad terminal.

Rough order-of-magnitude cost estimate:
No estimate was performed due to infeasibility at this station.

1.2 Times Square Station – 'S' Shuttle Platforms

Executive Summary: *Times Square Station has been determined to be feasible for APGs or PSDs. This report enumerates relevant feasibility criteria with a brief narrative and a rough order-of-magnitude cost estimate for the installation of APG/PSDs with certain qualifications. The ROM cost is estimated to be $17,291,403 in current dollars.*

The existing Shuttle platforms at Times Square Station are made up of three curved platforms serving three tracks and three, three-car trains. The new design for the Shuttle (contract A-35301 / 37116) fills in the center track, creates a new end loaded, island platform and moves trains further east to minimize the curved platform edges. The new larger center platform will serve two tracks running two longer six-car trains. See Figure 8 on the next page.

Full height PSDs: After the construction of Contract A35302 / A37116 there are a number of modifications that would be required to accommodate PSDs. Since the Contract A35302 / A37116 drawings do not represent an as-built condition, one can assume lighting on the station ceiling (whether existing lighting with conduit, wiring trough or Enhanced Station Initiative (ESI) - type integrated systems) would have to be reconfigured to accommodate full height PSDs. Ideally the PSD header beam could incorporate the required gap entrapment sensors, CCTV cameras, and lighting to replace what is on the ceiling. Alternatively the lighting, entrapment prevention sensors, and CCTV cameras would have to be relocated on the ceiling in coordination with full height PSDs. In either scenario lateral bracing of the full height system would have to be addressed.

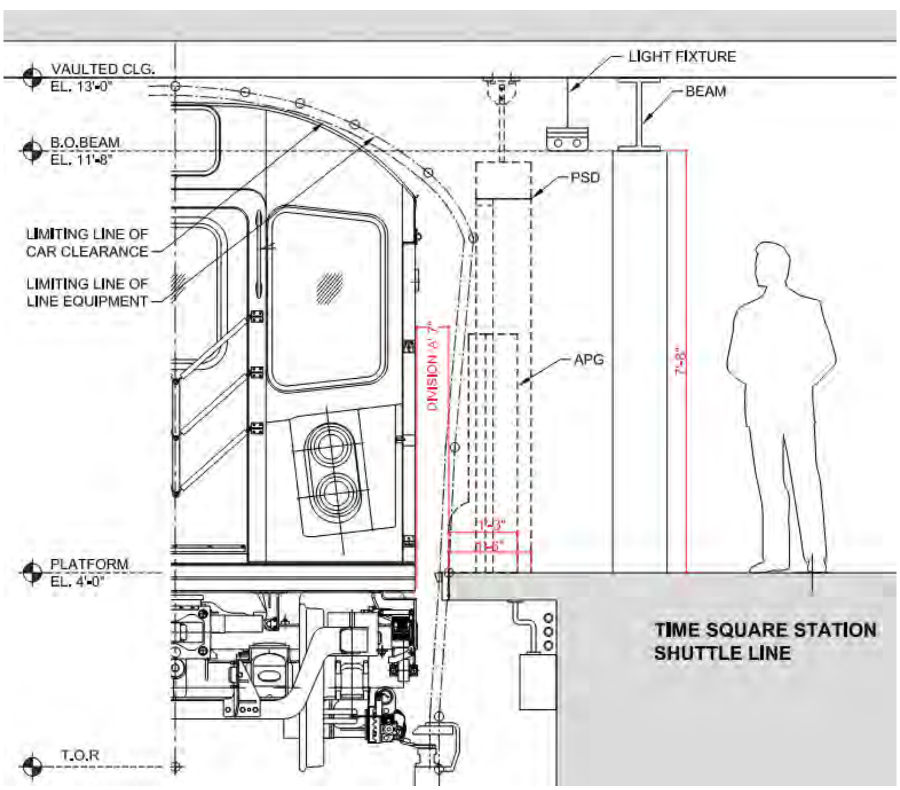

Figure 7 – Time Square Station Shuttle – Cross Section showing lighting on ceiling, clearance for full height PSDs and half height APGs

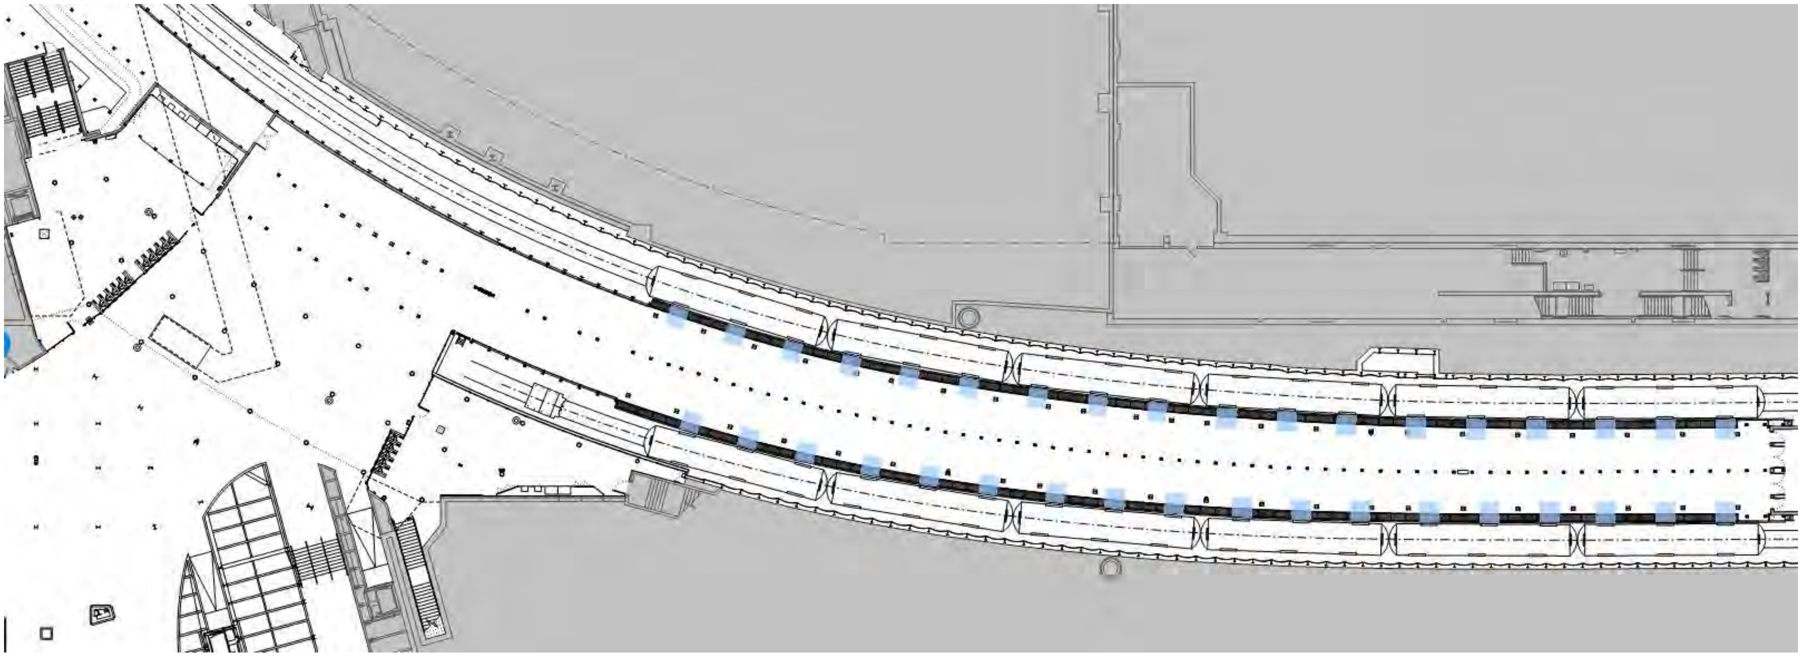

Figure 8 - Times Square Station Shuttle - Proposed future platform; north is to the top of the plan; notice tangent track at the east end of the platform

Half Height APGs: If APGs are installed they present a slightly simpler installation scenario. Ceiling mounted lighting would have to be reconfigured to accommodate APG entrapment prevention sensors and CCTV cameras, no other new systems would touch the ceiling. See Figure 7.

Equipment Room

Space required for equipment room is available at the west end of the platform in a non-public area. See Figure 9 below.

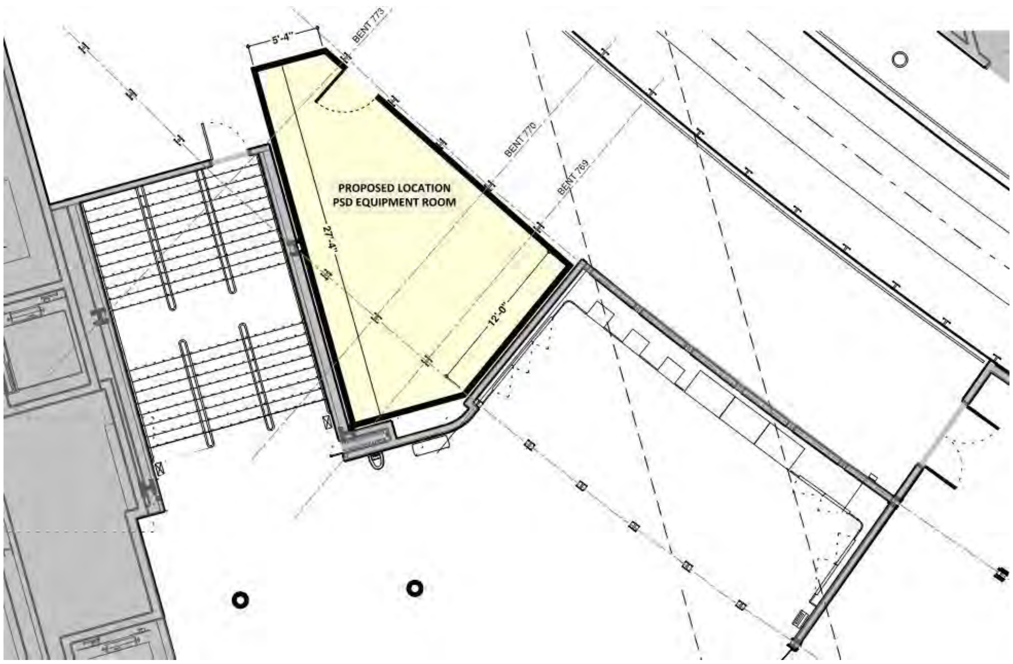

Figure 9 - Times Square Station Shuttle – space for PSD Equipment Room at east end

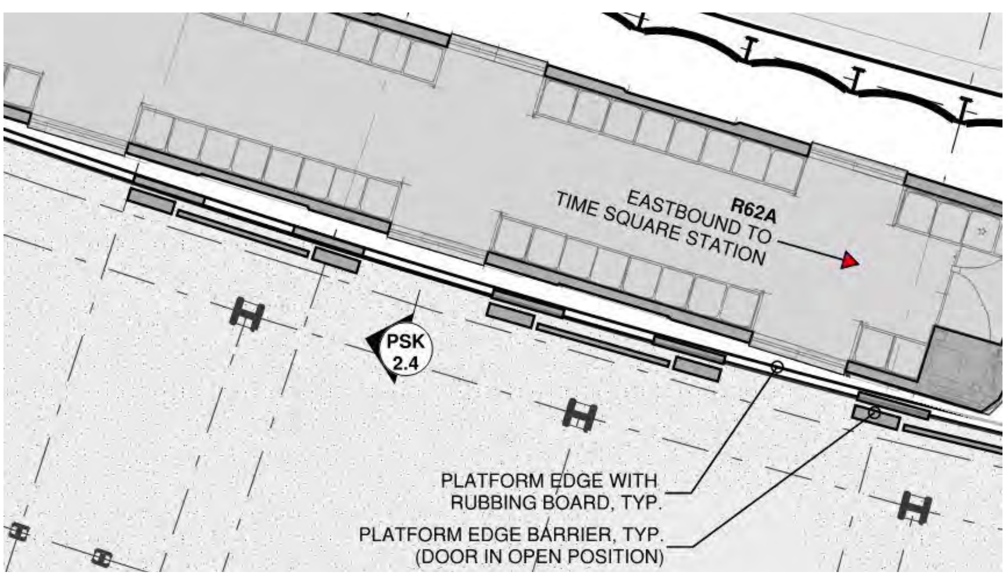

Figure 10 - Times Square Station Shuttle – curved track showing center gaps on north platform

Track Layout

Except at the extreme east end of the platform the track is curved which leads to larger gaps between the platform and the train as well as larger gaps between the train and the APG/PSD when compared to tangent track. There could be as much as five inches of center excess on the north edge, and five inches of end excess on the south platform edge. Due to these non-tangent gaps, the potential entrapment (eleven inches on tangent track) will now be approximately 16", increasing the potential for entrapment. A system of entrapment prevention sensors would developed in the design of the PSD/APG system to address this.

Platform edge condition

The new platform (Contract A-35302 / A-37116) is not designed to accommodate the structural loads of a PSD or APG system. If PAS/APGs are installed structural reconstruction of the platform edge would be required.

Platform obstructions within 5' of edge:

The design of the new columns places them 3'-8" from the platform edge. This will result in the partial obstruction of some doors but is not a fatal flaw. Since the new platform relies on existing curved track the ADA boarding area will be located at the east end of the platform corresponding to the ADA boarding area at GCS. This boarding area can remain compliant with APG/PSDs.

Lighting:

The Contract A-35302 / A-37116 documentation reviewed did not indicate the planned lighting scheme in detail except to show linear lighting near the platform edge. This future lighting, conduits, wiring trough or Enhanced Station Initiative (ESI) - type integrated systems on the station ceiling would have to be reconfigured with the full height PSDs or with CCTV and entrapment sensors for APGs.

Power:

Power is adequate based on planned reconstruction at Times Square.

See Electrical Capacity Analysis (Figure 11) on the next page based upon field observations at Times Square Station as well as Grand Central Station.

42nd Street Shuttle Line Electrical Capacity Analysis			
	Times Square, MR-468	**Grand Central, MR-469**	
	EDR (Only Normal Power)	EDR Normal	EDR Reserve
Station Peak - Peak Demand Load (Last 20 months)	72.8kW≡253A	85.6kW≡297A	
PSD - APG/PSD Load ('new' load) (Total Load for **36** doors, including all Miscellaneous Loads)	33.5kW≡116A	33.5kW≡116A	
Total Load (Station Peak + PSD)	369A	413A	
Station Service Capacity	1200A	1200A	1200A
Notes	Electrical Service is Adequate	Electrical Service is Adequate	
Based on 3 phase, 208V @ 0.8 P.F. Assumption: - 21.5 kW for 36 Doors/ Station; based on "APG" system manufacture. - 12.0 kW for Miscellaneous Loads (AC, Communication, Berthing, etc.) 6 Cars x 3 Doors x 3 Platforms			

Figure 11 - Electrical Capacity Analysis

Historic Restrictions:

The Shuttle at Times Square is a historically designated property. As such, design will require review by the New York State Historic Preservation Office.

Rough order-of-magnitude cost estimate:

Total cost for Times Square Station is estimated to be $17,291,403 in current 2018 dollars. This is based on a summary of expected costs developed through a review of conditions in the field, analysis of space constraints, length and numbers of doors (MSDs and EEDs), existing documentation and professional judgement. It is not based upon an actual conceptual design. The 'basis of estimate' assumptions are listed in the ROM estimate (Appendix, Section 2.3). The following factors have had an impact on the ROM estimate:

- Reconfiguration of existing lighting, conduits, wiring trough or ESI - type integrated systems on the station ceiling is assumed to be typical of found conditions on other low ceiling, below grade stations.

- Coordination of existing ceiling mounted systems and fixtures is likely to be marginally higher for full height PSDs.
- New platform edges at Times Square Station are not designed to accommodate the structural requirements for PSD/APG systems, the cost estimate includes the reconstruction of the platform as well as replacement of the concrete topping and finish along the platform edges to accommodate the PSD/APG installation.

Table of Contents

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**

5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

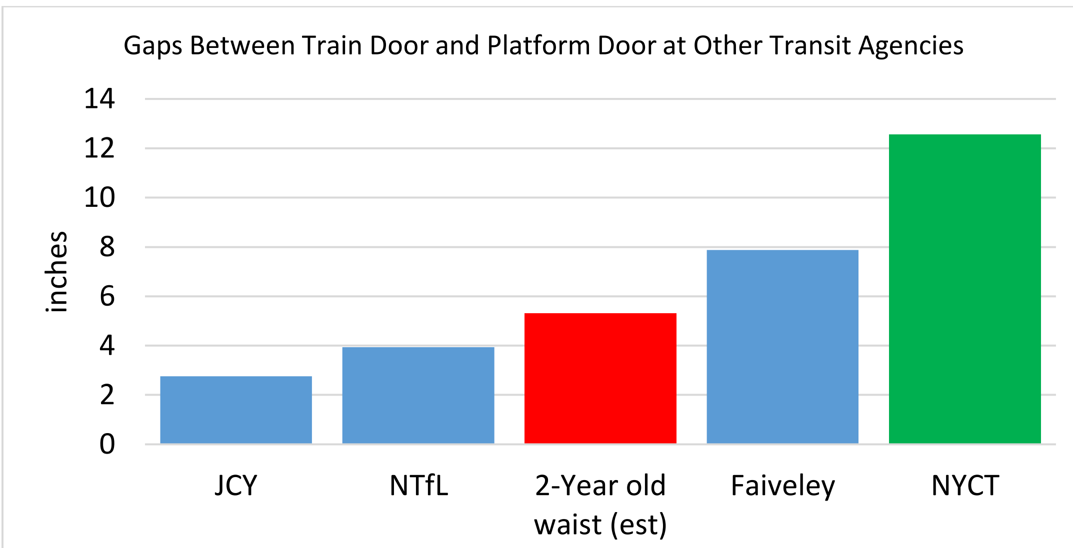

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

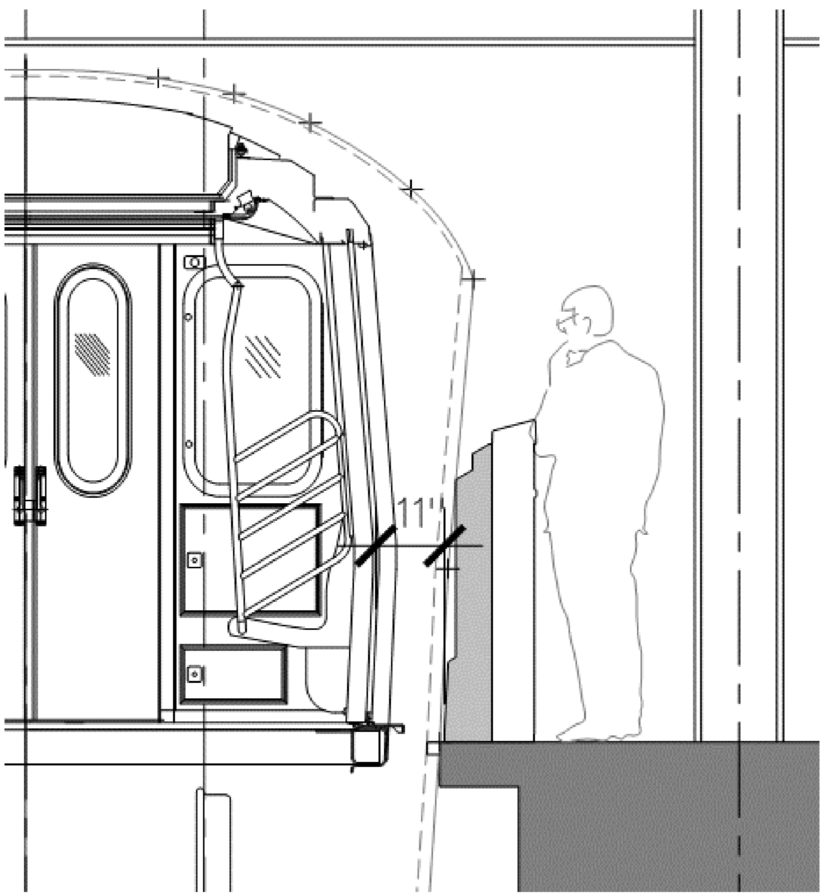

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

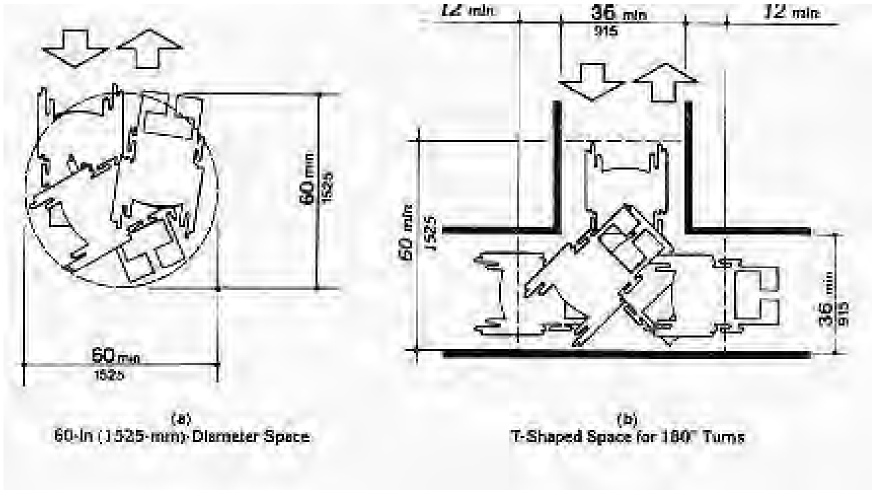
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

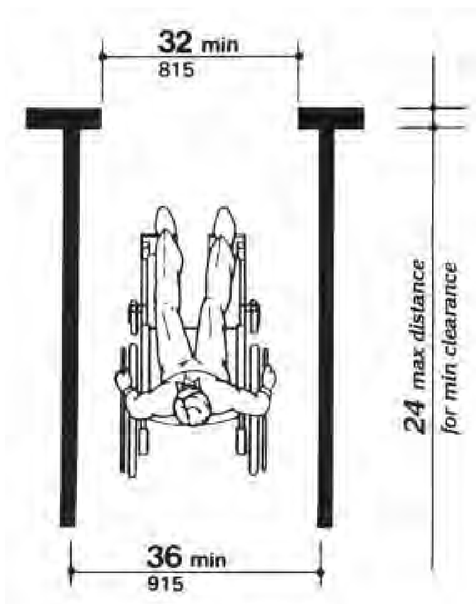


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

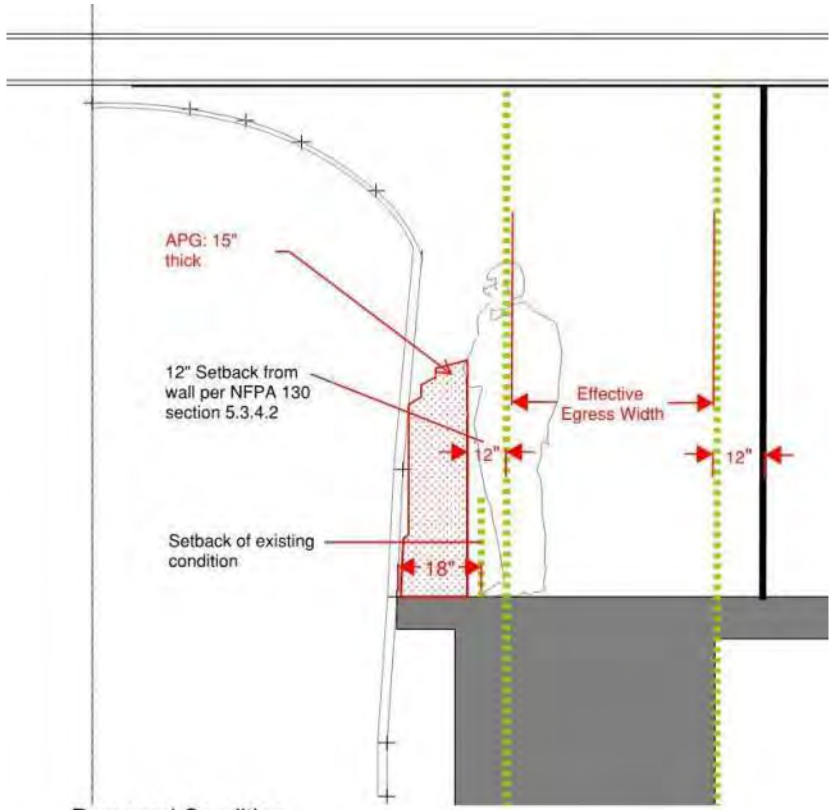
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Appendix B

New York City Transit

REPORT ON STRUCTURAL FEASIBILITY OF PLATFORM EDGE BARRIERS FOR SYSTEM-WIDE INSTALLATION

NEW YORK CITY SUBWAY SYSTEM

April 19, 2018

CONTRACT #: C-32514 | STV PROJECT #: 3017214

STV 100 Years

Table of Contents

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the United States and the world, with the intent of preventing customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

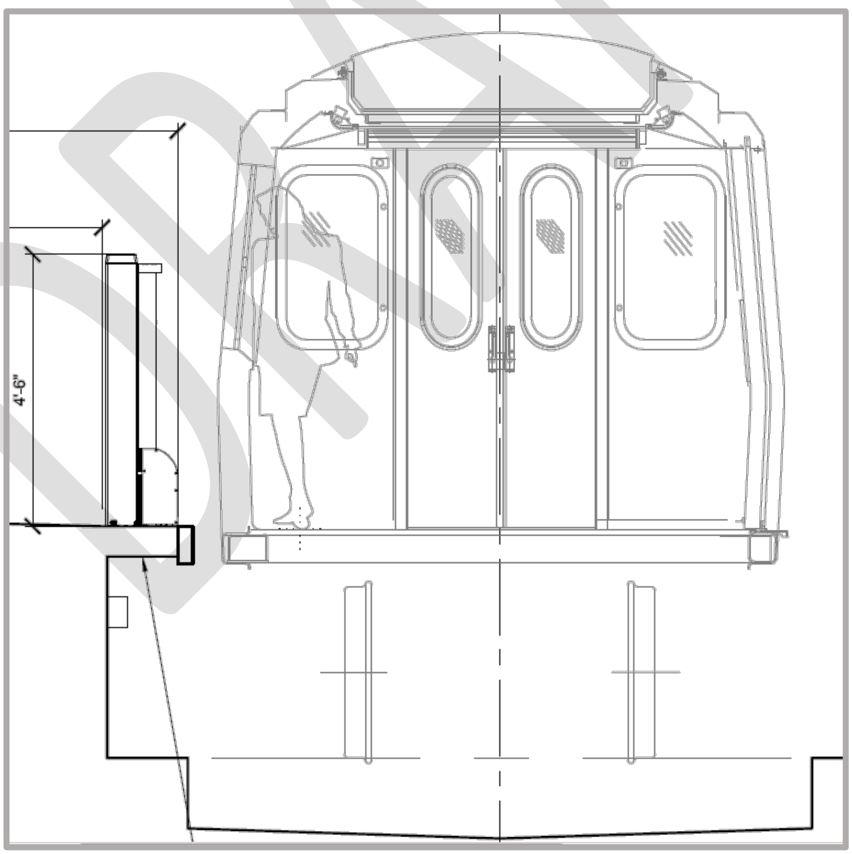

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

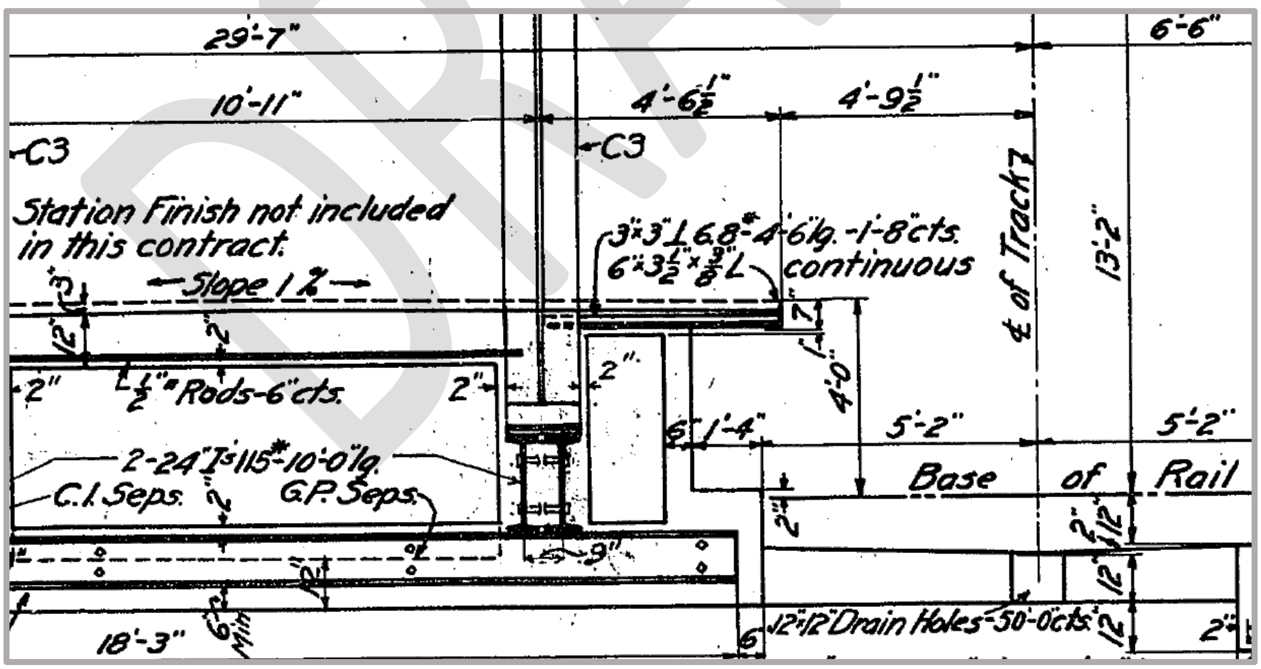

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

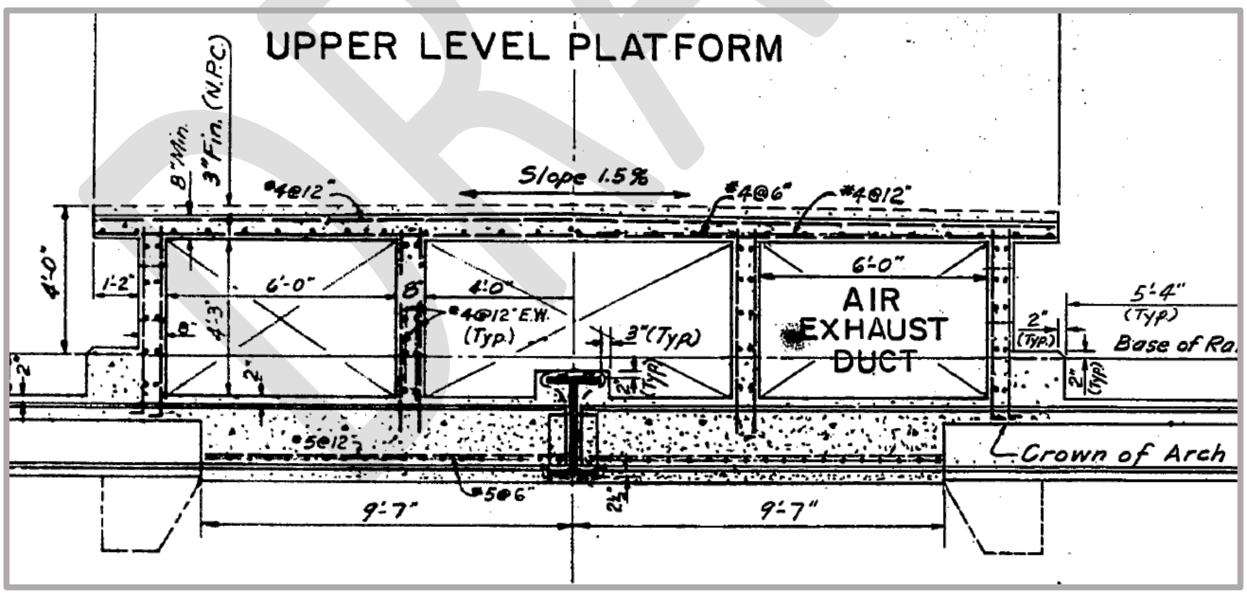

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

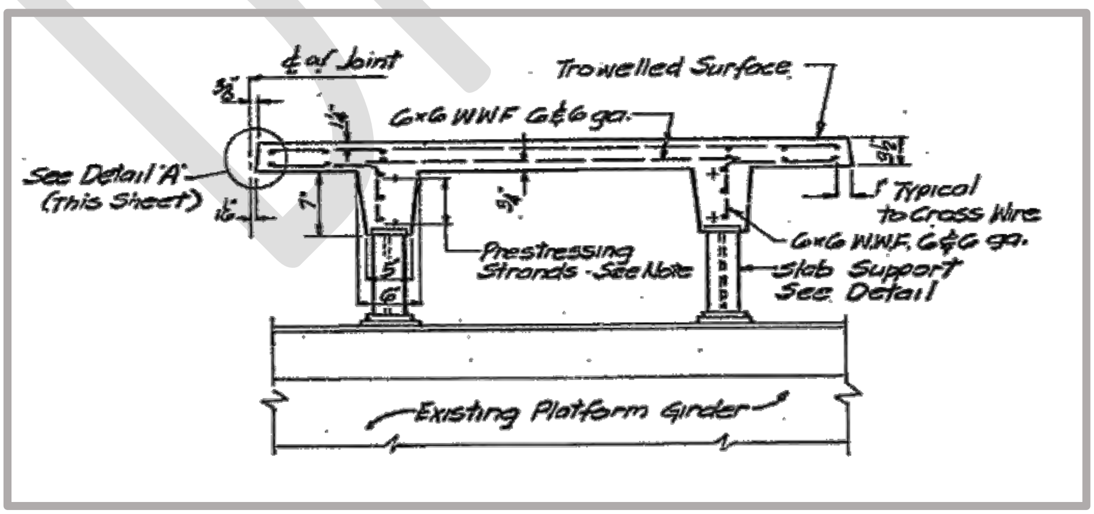

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See ***Figure 4-4*** *Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)****Figure 4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

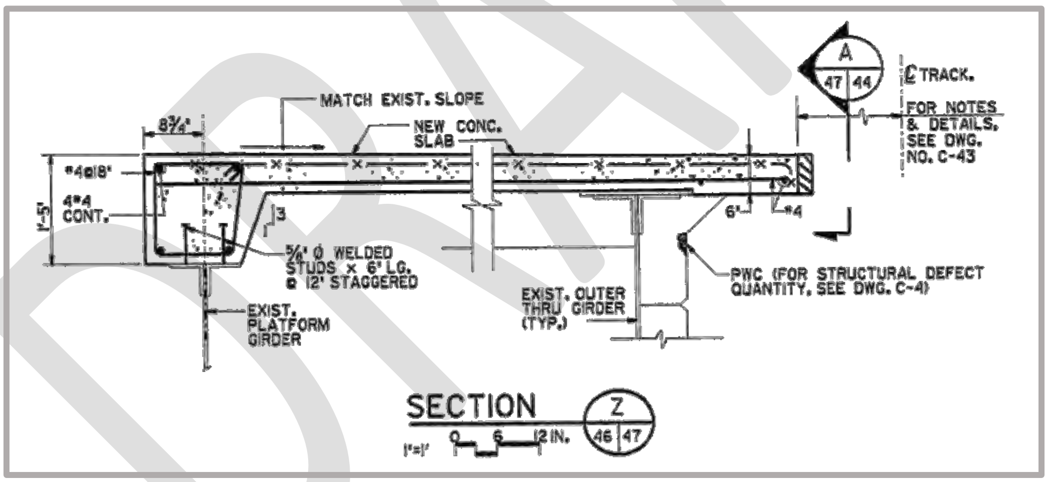

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. While the platform slab is cast-in-place concrete, it has a longer cantilever than elsewhere in the system (approximately 2'-9") and cannot support the PSD system. As a result, a portion of the platform slab would have to be rebuilt with additional reinforcing. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

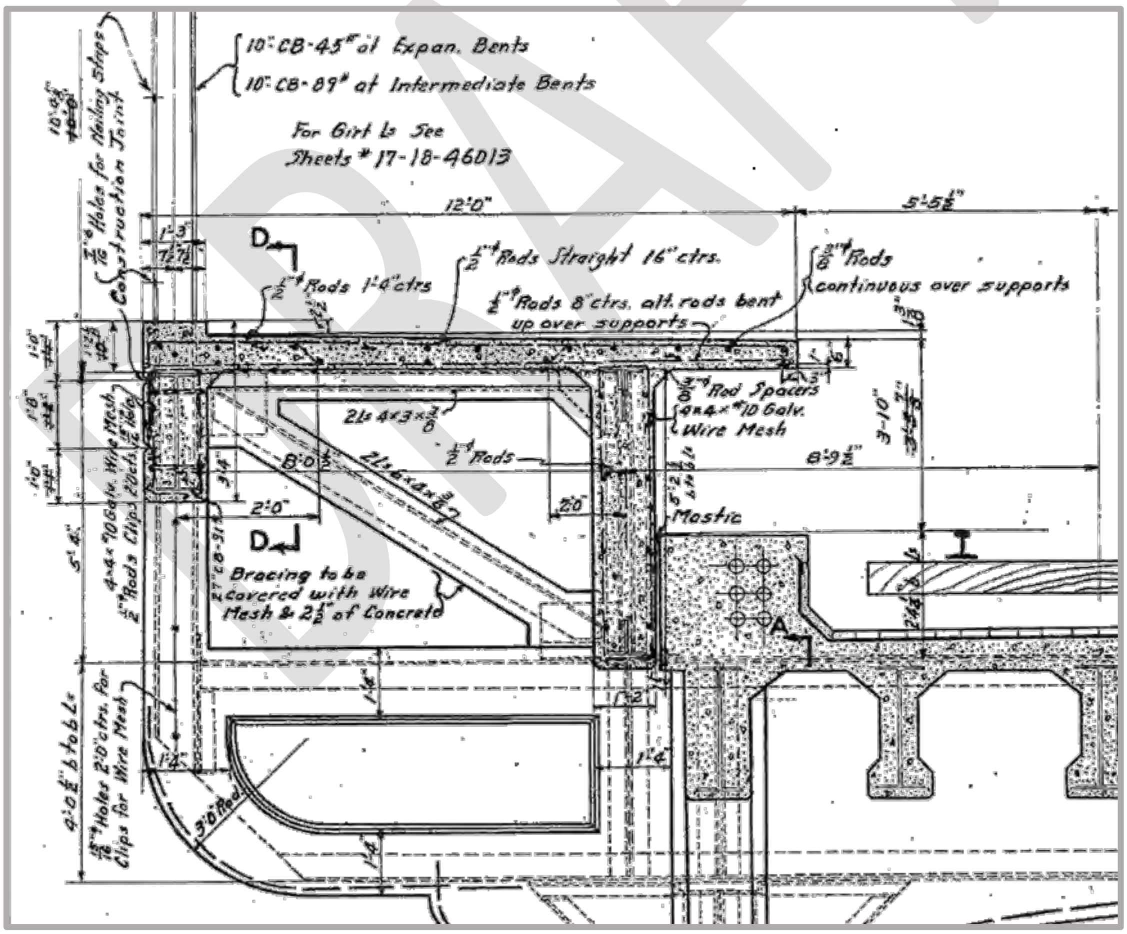

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

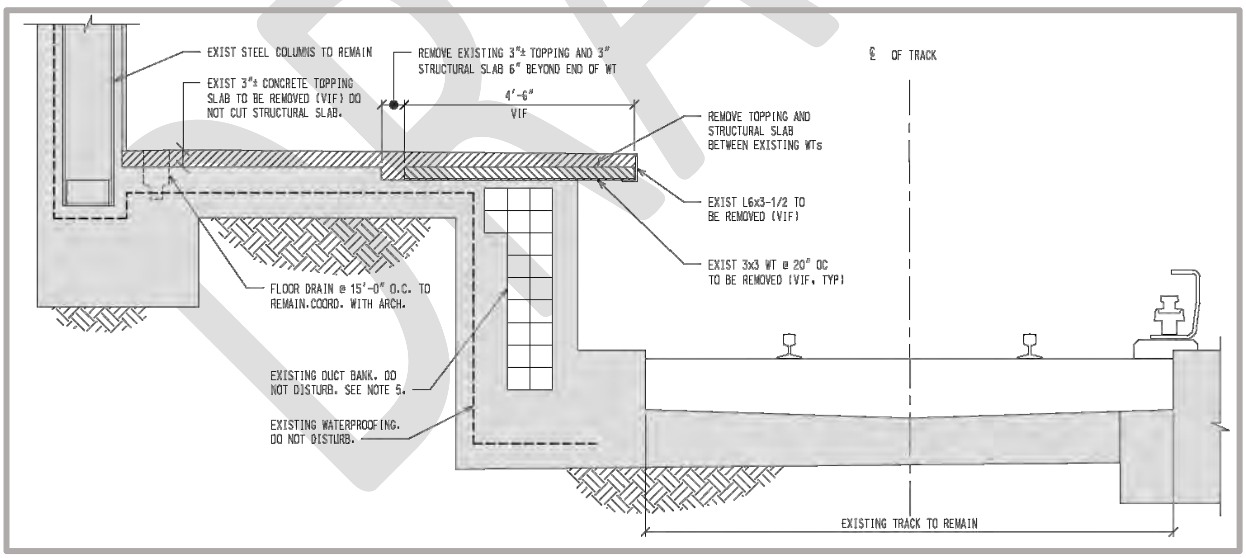

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

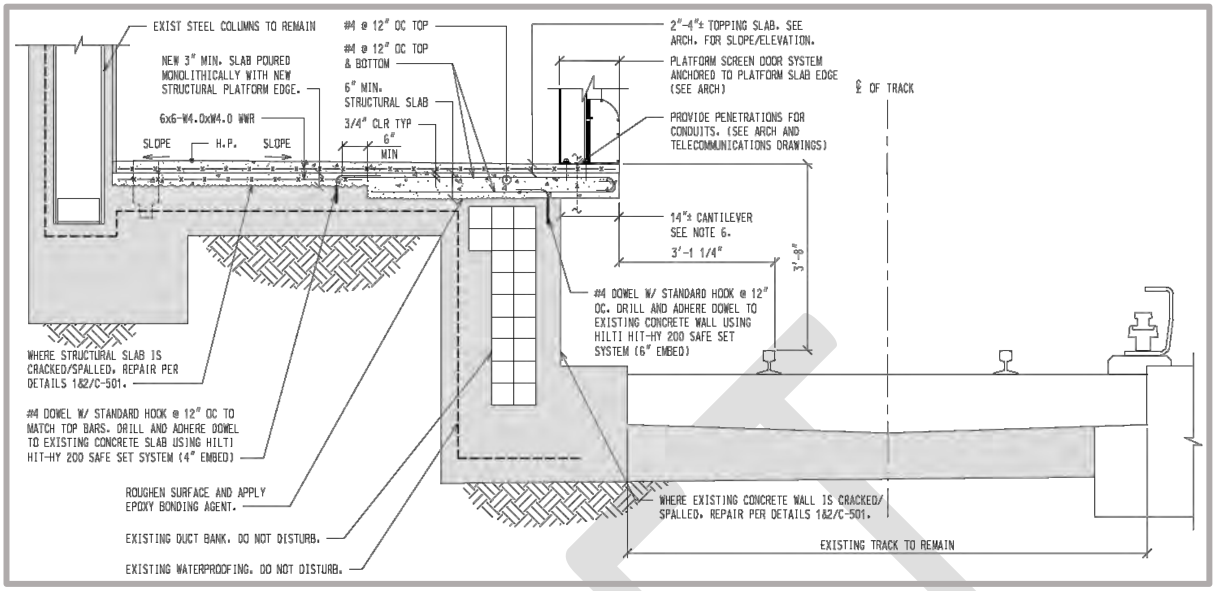

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

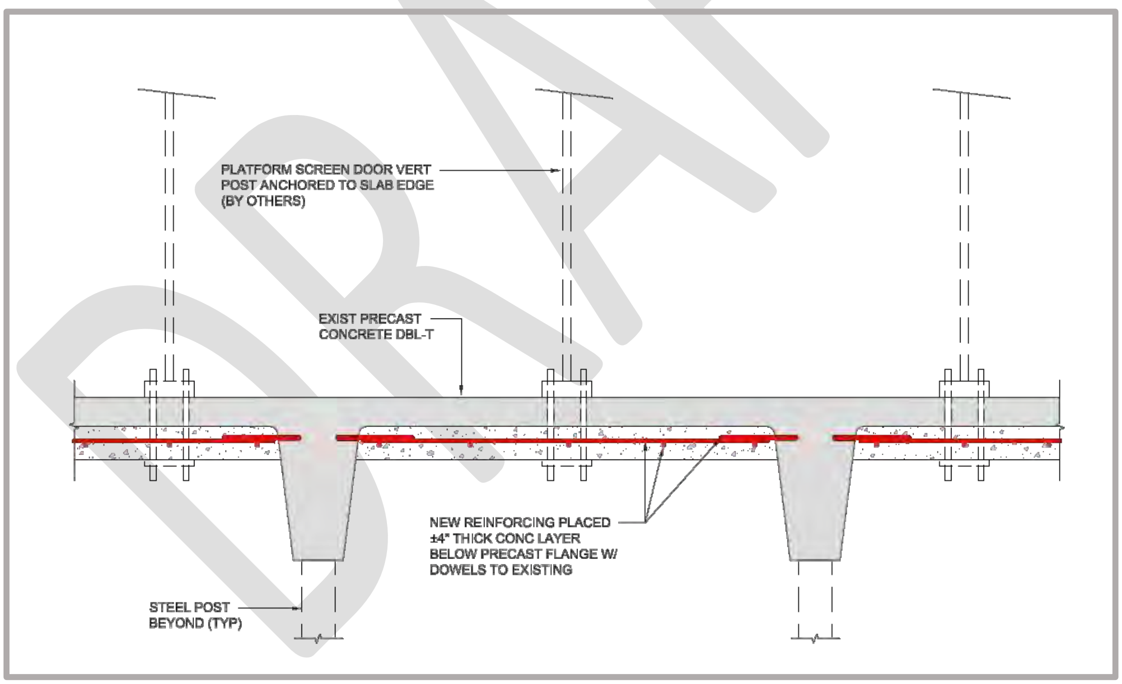

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

ORDER OF MAGNITUDE COSTS

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 42nd Street Shuttle Line Stations

MTA/NYCT

April 30, 2018

BASIS OF ESTIMATE

9.00 ***Description of typical APG / PSD installation:***

9.0.1 *APGs / PSDs will provide 22 emergency egress doors with push bars per platform*
9.0.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
9.0.3 *Each platform edge will have 30 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
9.0.4 *Control Rooms will be as documented; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on platform)*
9.0.5 *Each Control Room will serve two platform edges*
9.0.6 *Control Rooms will be cooled to maintain operability of the control equipment*
9.0.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
9.0.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

9.0.9 *The existing platform edge lighting to be installed under contract A-35302 / A37116 is to be coordinated to suit the requirements of the PSD's*

BASIS OF ESTIMATE

9.0.10 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

9.1 ***Assumptions:***

9.1.1 *Two-foot wide platform edge finish and topping slab will be removed down to the structural slab and new granite tile/tactile warning tile will be installed on the platform side of the APGs (assumed width of finish on platform side of APGs is 1'-0")*

9.1.2 *All platforms will require structural rehabilitation to take APG loads*

9.1.3 *There are no special security requirements made necessary by installation of the APG system*

9.2 ***Exclusions - Costs not included in the estimate:***

9.2.1 *Costs associated with construction of remote Control Rooms (at locations other than inside the station)*

9.2.2 *Costs associated with changes to train signals or systems*

9.2.3 *Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length*

9.2.4 *Costs associated with NYCT State Of Good Repair improvements to the station*

BASIS OF ESTIMATE

9.2.5 *Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.*

9.2.6 *For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs*

9.3 ***Below the line or "soft" costs:***

9.3.1 *Design and Construction Contingency*
9.3.2 *Contractor O & P*
9.3.3 *Insurance*
9.3.4 *NYCT project costs not included*

9.5 ***Additional Notes***

9.5.1 *Given the limited time available, no drawings were developed to support this estimate.*

STATION: TIMES SQUARE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [TRACK 1] =	315	LF		
5	LENGTH OF THE PLATFORM EDGE [TRACK 4] =	306	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	621	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	621	LF	$7.00	4,347
13	Remove 5' wide section of 3" deep structural slab to platform edge	3,105	SF	$12.00	37,260
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	63	CY	$2,500.00	157,500
16	Pair of dowels (front & rear) cast into existing at 12" O.C	1,246	EA	$25.00	31,150
17	Cast in assemblies for PSD holding down bolts	384	EA	$180.00	69,120
18	Provide sleeves for HV & LV wires	192	EA	$110.00	21,120
19	Polyethylene edge strip	621	LF	$95.00	58,995
20					
21	Platform edge finishes				
22	Demolition				
23	Remove existing tactile warning strip 2' wide	621	LF	$15.00	9,315

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 42nd Street Shuttle Line Stations

30-Apr-18

STATION: TIMES SQUARE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
24	Remove existing platform tiles	2,484	SF	$8.00	19,872
25	Sawcut existing topping concrete at perimeter of removal area	621	LF	$5.00	3,105
26	Remove existing 3" concrete topping; Assuming 6' wide strip	3,726	SF	$8.00	29,808
27	New Work				
28	New concrete topping to match existing	621	SF	$15.00	9,315
29	New Granite tiles to match existing	1,908	SF	$60.00	114,480
30	Provide new 2' wide Tactile Strip at location of doors only	288	LF	$110.00	31,680
31	Misc. patchwork	1	LS	$50,000.00	50,000
32					
33	**Equipment Room [Refer PSK 2.3]**				
34	Build off existing track level		Note		
35	Form 8" wide concrete curb including dowelling to platform slab	79	LF	$90.00	7,110
36	CMU Wall for equipment room - Assume 8' high	632	SF	$45.00	28,440
37	Fire rated door including frame & hardware	1	EA	$2,500.00	2,500
38	Exterior wall finish				
39	Ceramic Tiling to match existing	360	SF	$40.00	14,400
40	Mosaic Band to match existing - Assuming 8" high	36	LF	$120.00	4,320
41	Concrete cove to match existing	36	LF	$20.00	720
42	Interior Wall Finish - Paint	632	SF	$5.00	3,160
43	Allow for Misc. floor & ceiling finishes	340	SF	$15.00	5,100
44	Allow for 4" thick concrete pads for equipment	85	SF	$20.00	1,700
45	Allowance for Mechanical Scope	1	LS	$40,000.00	40,000
46	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	$60,000.00	60,000
47	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	$100,000.00	100,000
48	Allowance to bring fiber optic to Control Room from network node	1	LS	$15,000.00	15,000
50	**Automatic Platform Gates [APGs] - 4'-6" High**				
51	Automatic bi-parting gates; Assumed 6'-0" wide (6 Cars x 4 Doors = 24 No. per platform)	48	EA	$15,000.00	720,000
52	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #22 per Platform	44	EA	$10,500.00	462,000

30-Apr-18

STATION: TIMES SQUARE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
53	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	$20,000.00	40,000
54	Platform End Gates (PEGs)	4	EA	$13,000.00	52,000
55	Fixed Panels including framing and support; 4'-6" High	905	SF	$850.00	768,825
56	Spare Parts - Approx. 10% of Material Cost	1	LS	$180,000.00	180,000
57	Testing and commissioning	800	HRS	$159.93	127,944
58	Product Warranty	1	LS	$1,000,000.00	1,000,000
59	Allowance for Braille Signage	48	EA	$2,500.00	120,000
60					
61	Electrical				
62	Electrical Upgrades				
63	Reference Tier 2/3 Report [Page 7 of 9], there is adequate power is available to cater for additional load required by above scope		Note		EXCL.
64	Power and Lighting				
65	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	$200,000.00	200,000
66	Allow for conduit / cable runs for power and communications under platform edge	2,484	LF	$60.00	149,040
	PSD Connections	1	LS	$75,000.00	75,000
68	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	LS	$200,000.00	200,000
69	Allowance to bring power to Equipment Room from EDR including track crossing	1	LS	$20,000.00	20,000
70	Reference Tier 2/3 Report [Page 1 of 9], No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
71	Grounding				
72	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	LS	$30,000.00	30,000
73	MISC				
74	Testing and commissioning	1	LS	$30,000.00	30,000
75	As Built, Shop Drwgs, Permits and approvals	1	LS	$20,000.00	20,000

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR 'S - FRANKLIN LINE' SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: July 26, 2019

STV 100 Years

Table of Contents

Appendices

Appendix A: Tier 2-3 Technology assessment

Appendix B: Structural Feasibility Report

Appendix C: Emergency Egress Width Analysis

Appendix D: maintenance Cost Estimate

Appendix E: Rough Order of Magnitude Costs

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 4 newly evaluated stations, 1 has been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic

upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is not used for refuse removal at the Franklin Avenue shuttle stations. Therefore no special provisions are necessary to accommodate the collection of refuse along the platform edge barrier.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 75% of the 'S' Line Stations. Total implementation cost would be \$36.9M for APGs and \$41.3M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of \$931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 3 feasible stations, the aggregate annual maintenance cost would be \$2.8M.

Table of Content

Summary Table

(75% Feasible 3/4)

MRN No.	Station Names	Station Type	Platform Type	Feasibility	Issues/Reason for Failure	Cost APGs	Cost PSDs
042	Prospect Park	CUT	Island	No	ADA Clearance	-	-
139	Franklin Avenue	ELV	Side	Yes		$11.4M	$12.5M
141	Park Place	ELV	Side	Yes		$11.3M	$12.4M
142	Botanic Gardens	SUB	Side	Yes		$14.1M	$16.4M
					TOTAL	**$36.9M**	**$41.3M**

1.0 Station Assessments

1.01 – MR 042 | Prospect Park Station

Summary: *Prospect Park Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Prospect Park Station is an open cut station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms at the north end is 3'-10". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

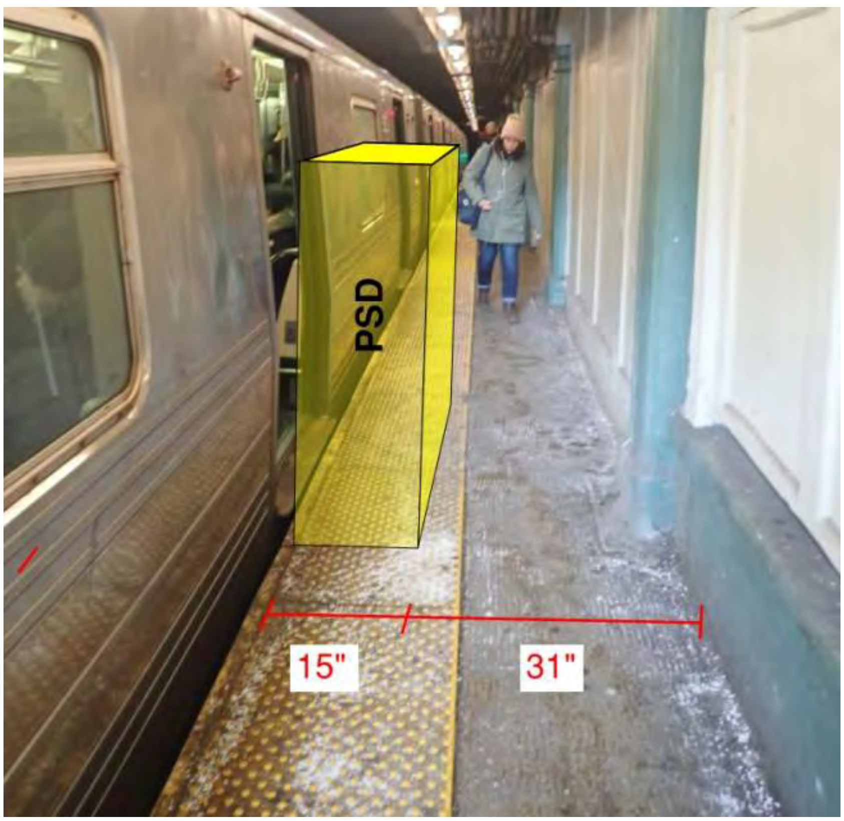

Figure 1 *– Non-compliant ADA condition*
Prospect Park Station

1.02 – MR 139 | Franklin Avenue Station

Summary: *Franklin Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Franklin Avenue Station is an elevated station with one straight side platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are no platform columns. The platform width varies from approximately 11'-6" to 24'-4". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the center of the platform, flush to the back wall (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

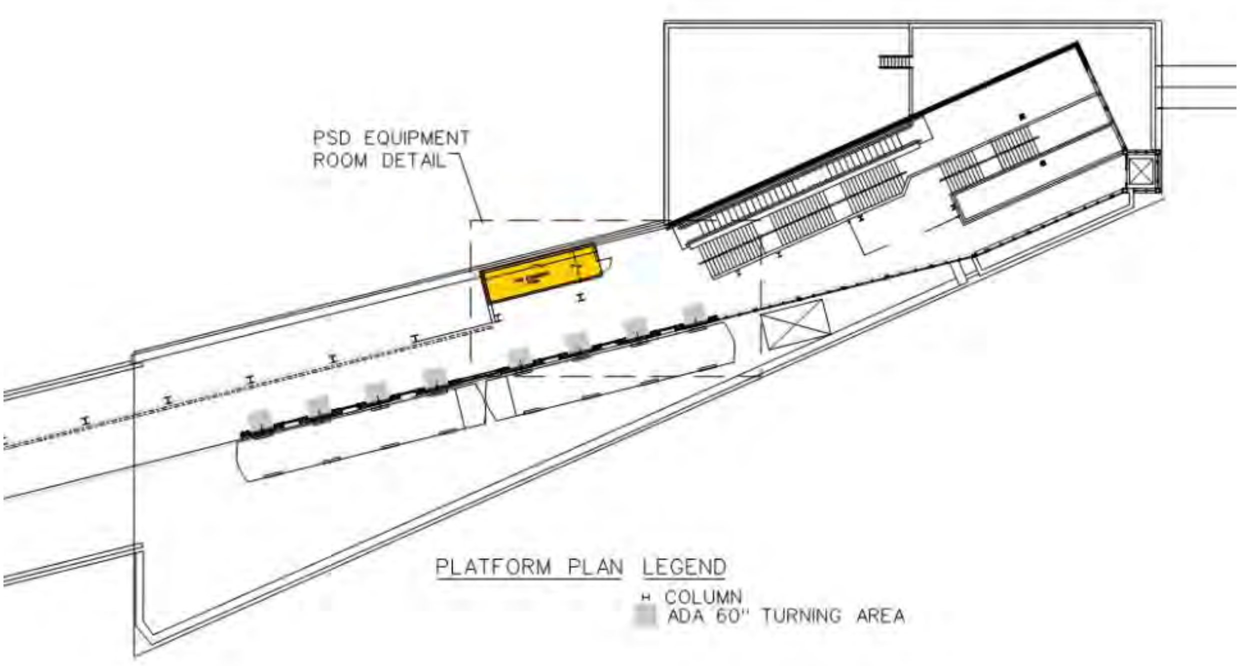

Figure 1 – *Overall Station Plan*
Franklin Avenue Station

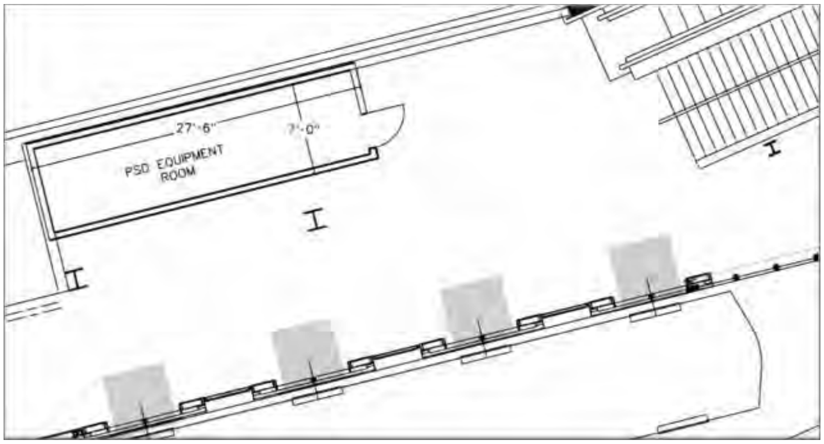

***Figure 2** – PSD Equipment Room 1 Detail*

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout the platform there is linear florescent lighting parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Franklin Avenue
Peak Demand Load from ConEd Report, (kW)	66.4

Franklin Avenue Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $11.4M to install APGs and $12.5M to install PSDs (See Appendix E).

1.03 – MR 141 | Park Place Station

Summary: *Park Place Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Park Place Station is an elevated station with one straight side platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are no platform columns. The platform width is approximately 11'-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at grade near Prospect Place. (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $11.3M to install APGs and $12.4M to install PSDs (See Appendix E).

1.04 – MR 142 | Botanic Gardens Station

Summary: *Botanic Gardens Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Botanic Gardens Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platform columns are set 8'-8" from the platform edge. The platform width varies from approximately 8'-0" to 17'-8". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	Comments
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

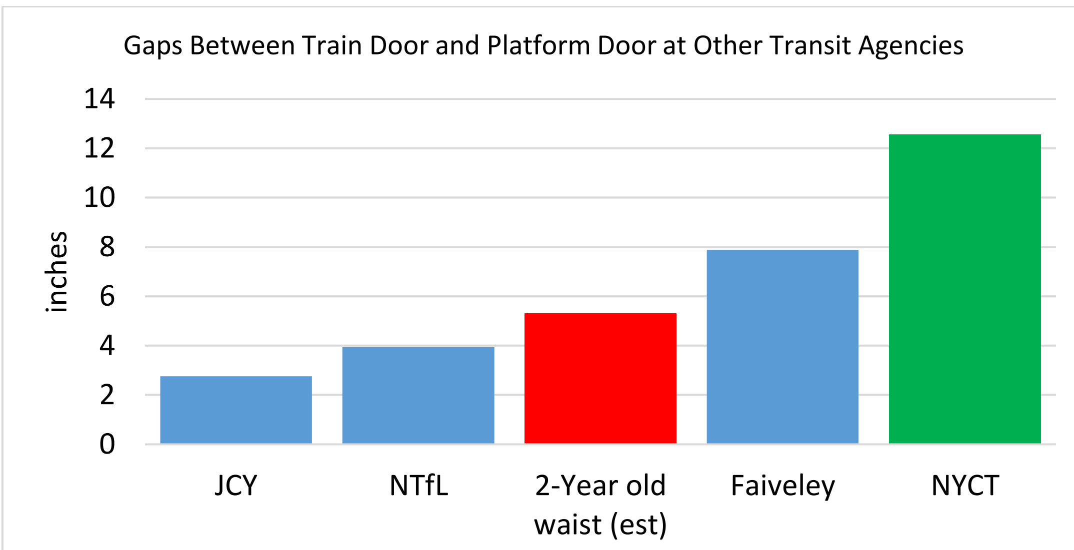

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

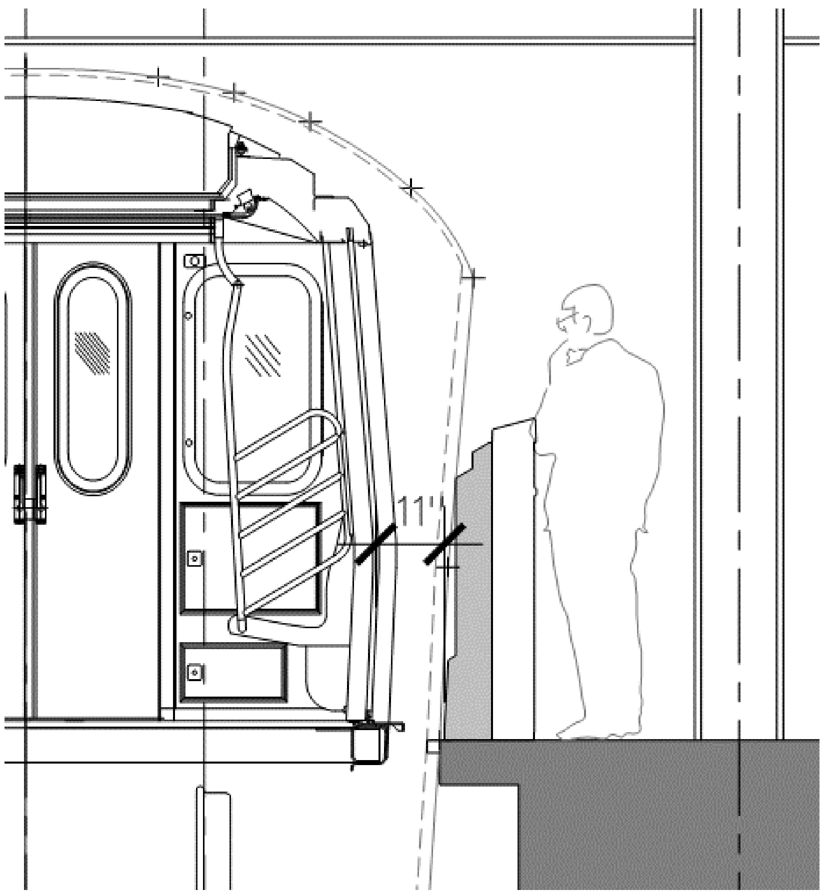

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

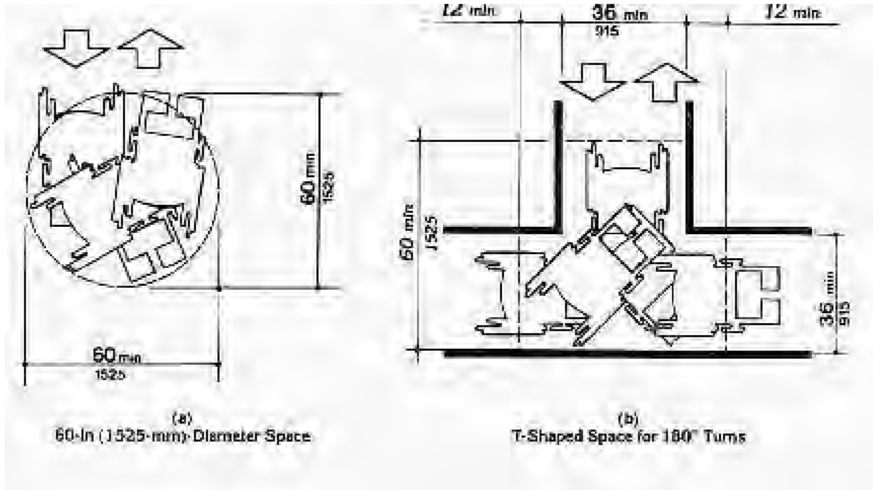
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

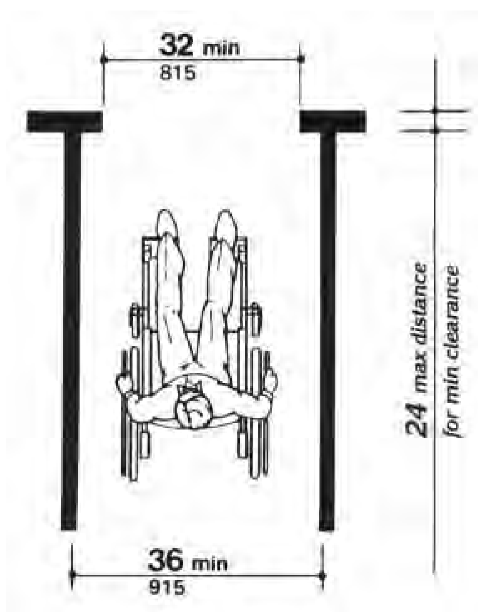


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

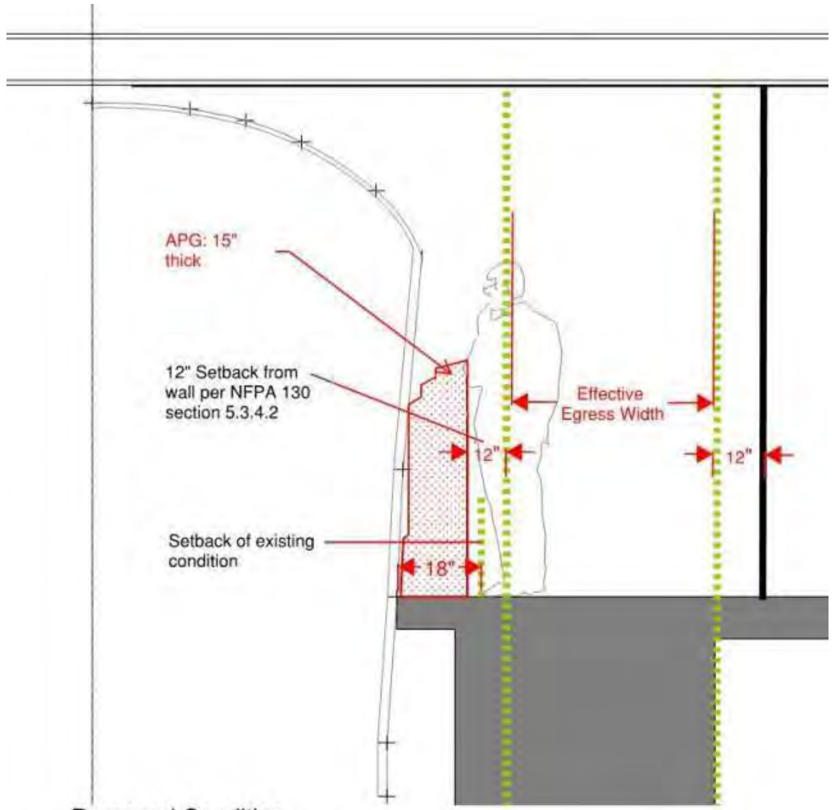
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

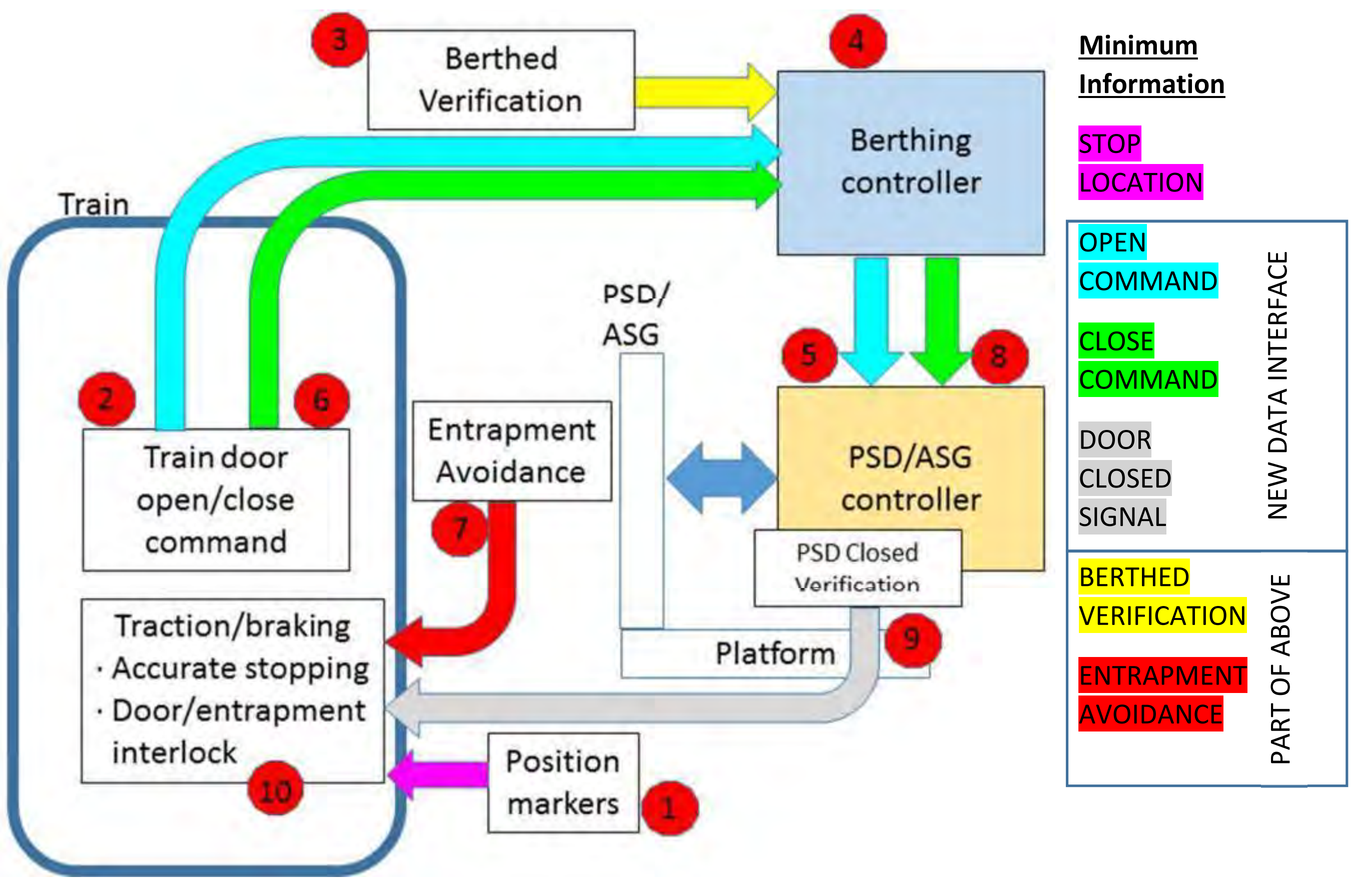
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

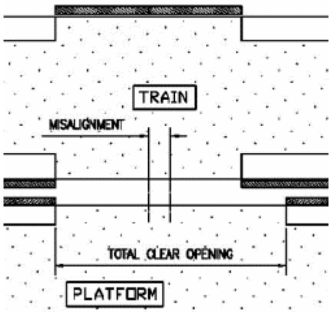
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

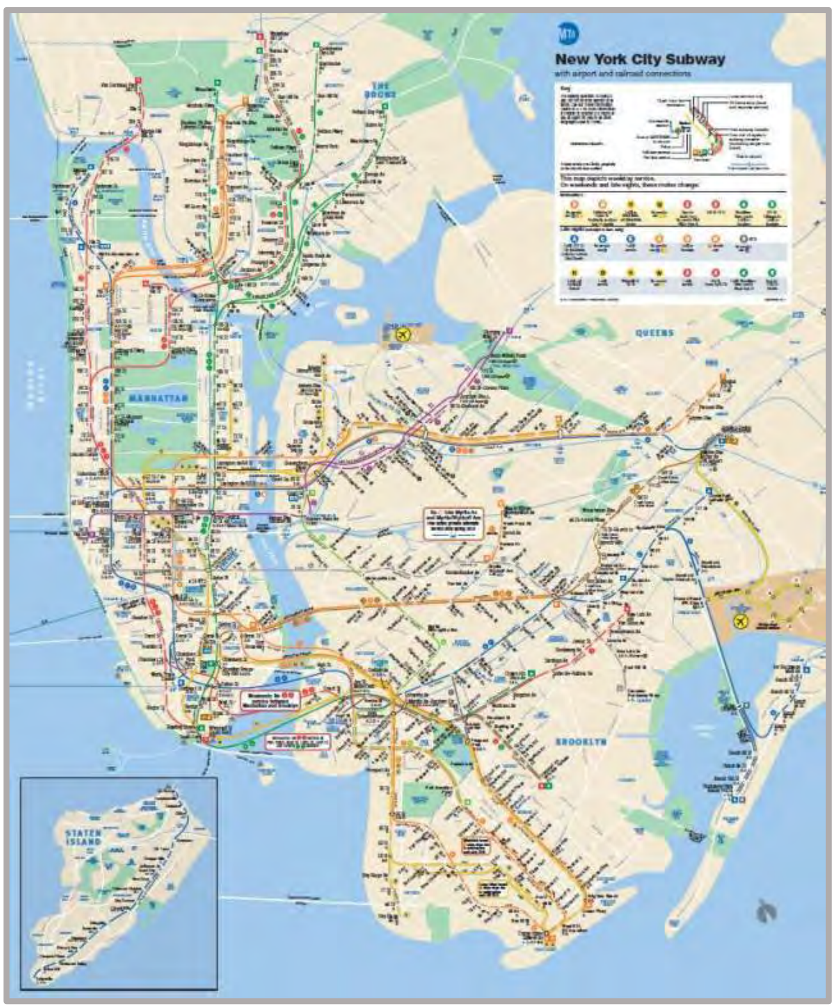


Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

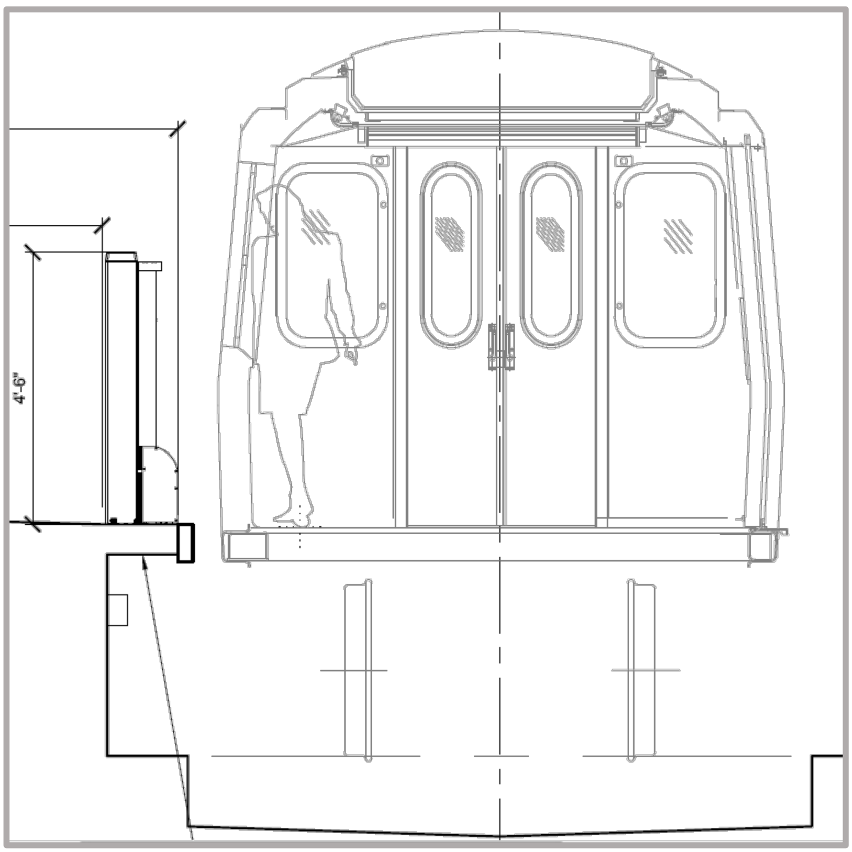

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

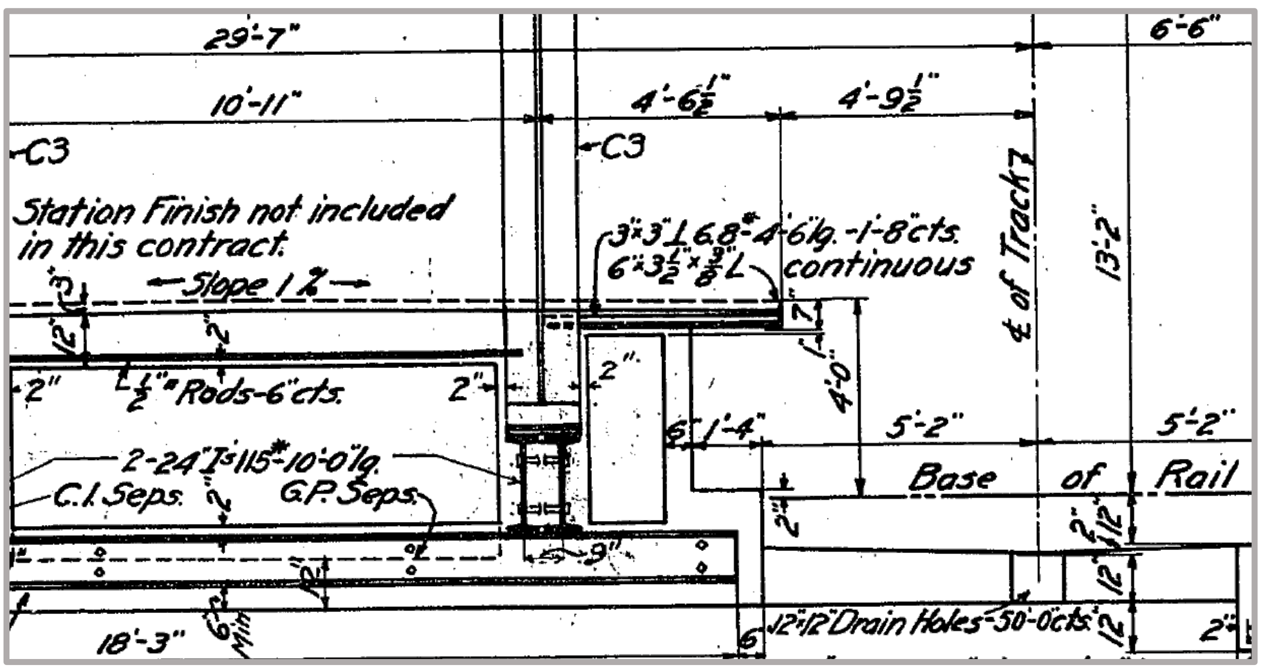

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

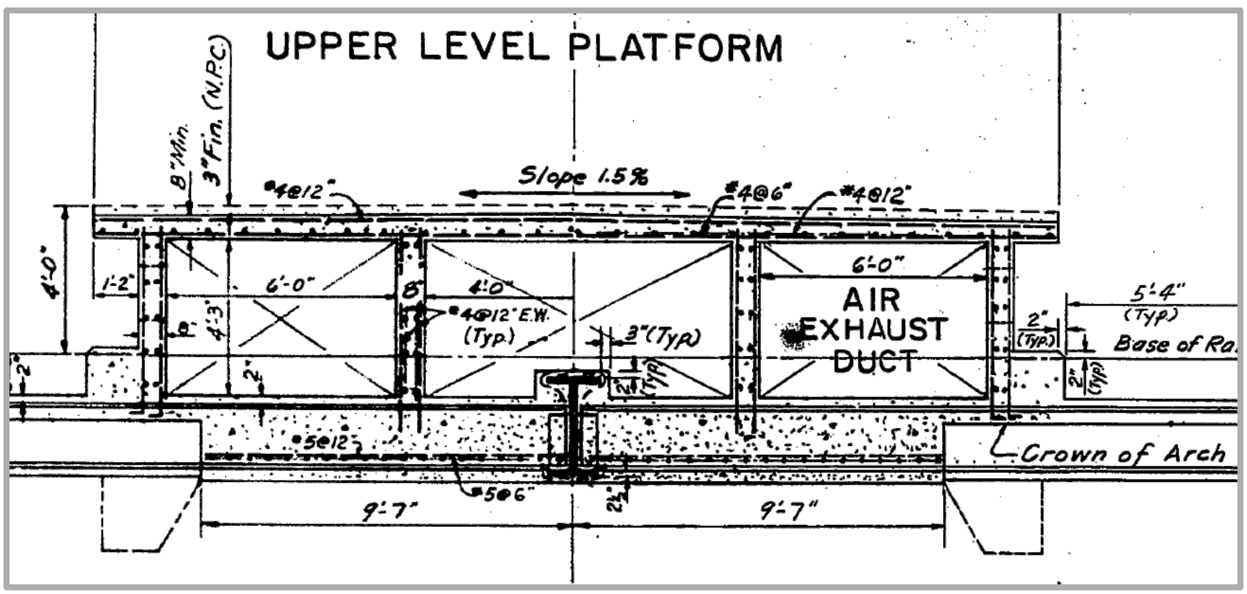

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

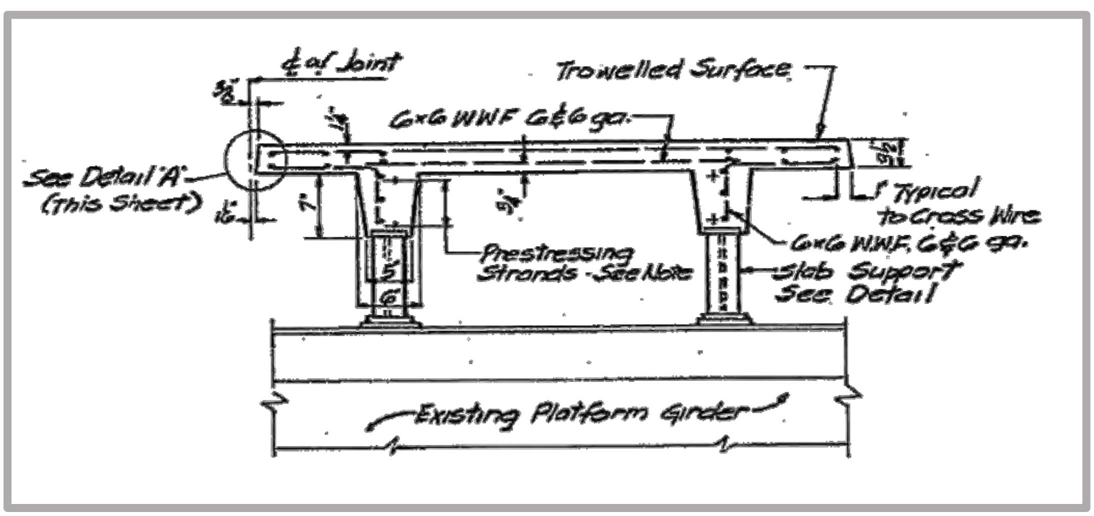

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

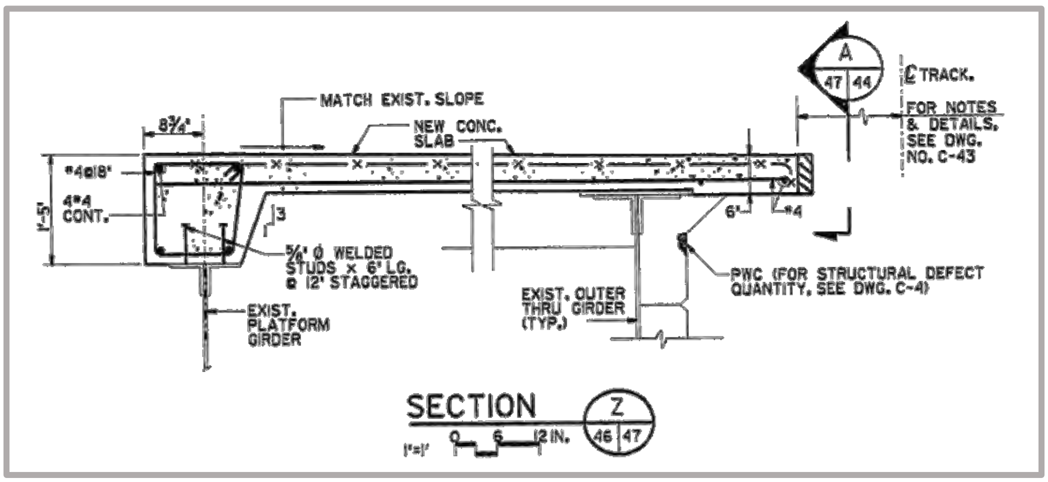

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2’-9”), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

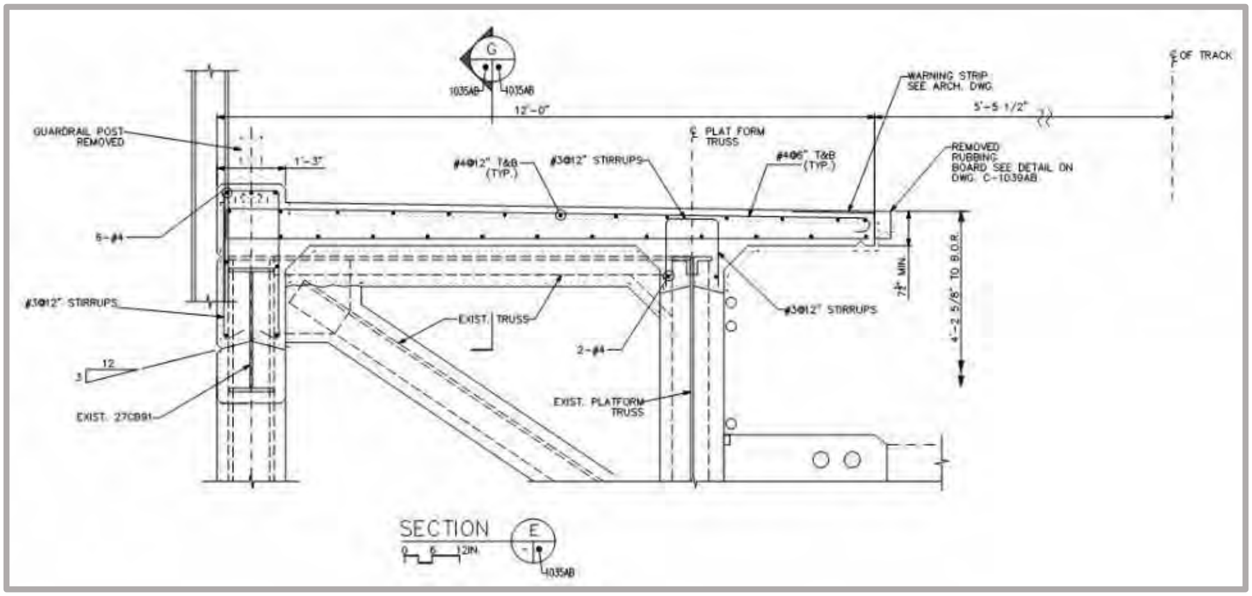

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

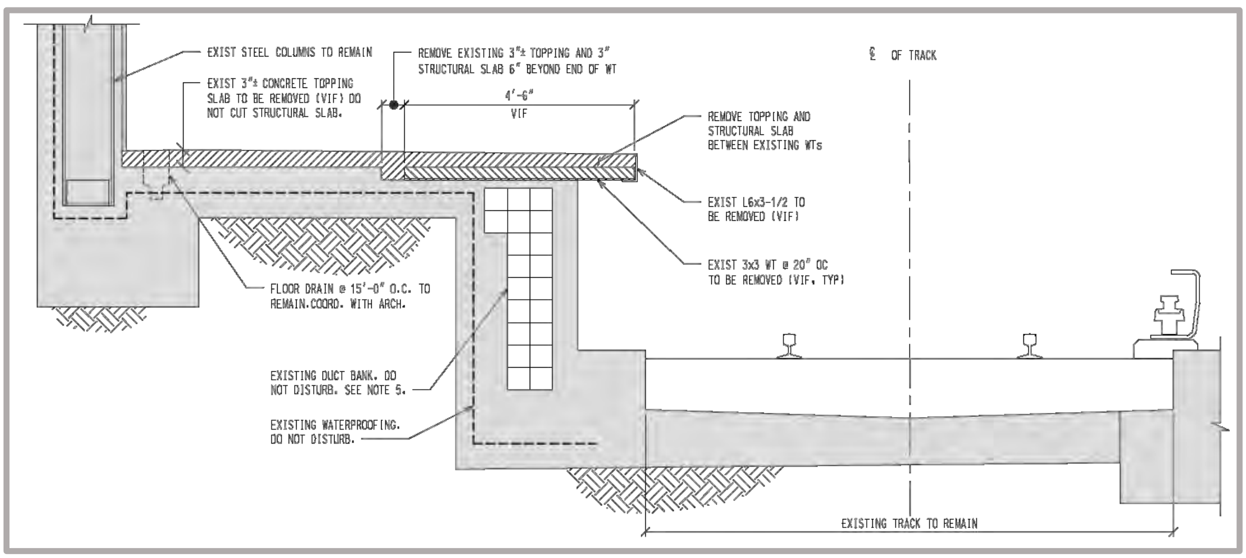

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

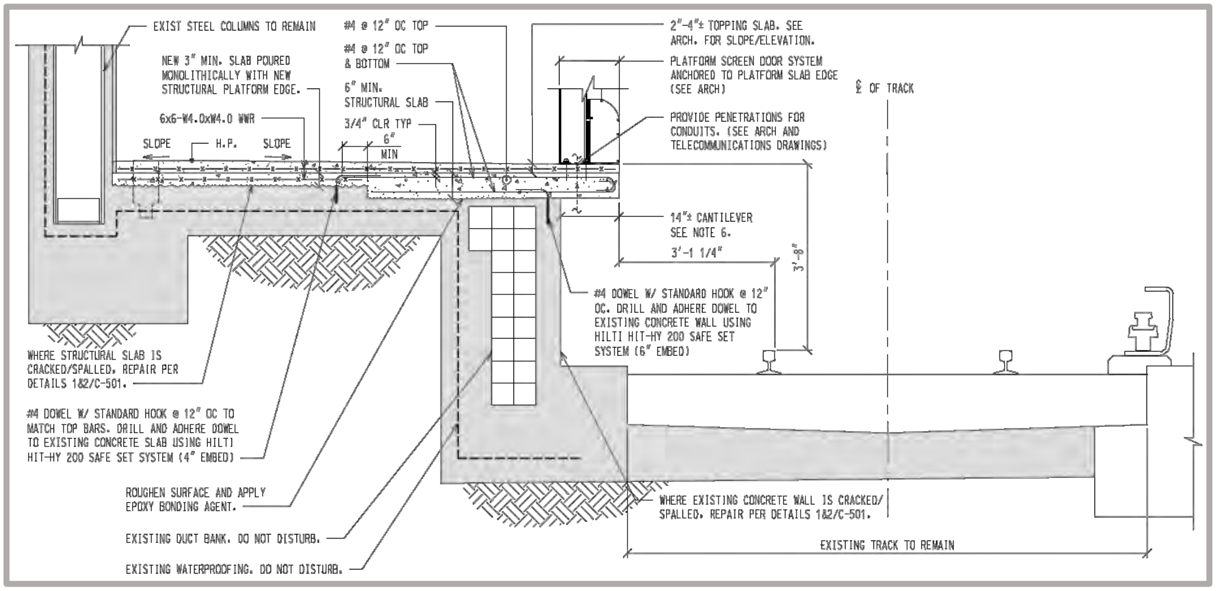

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

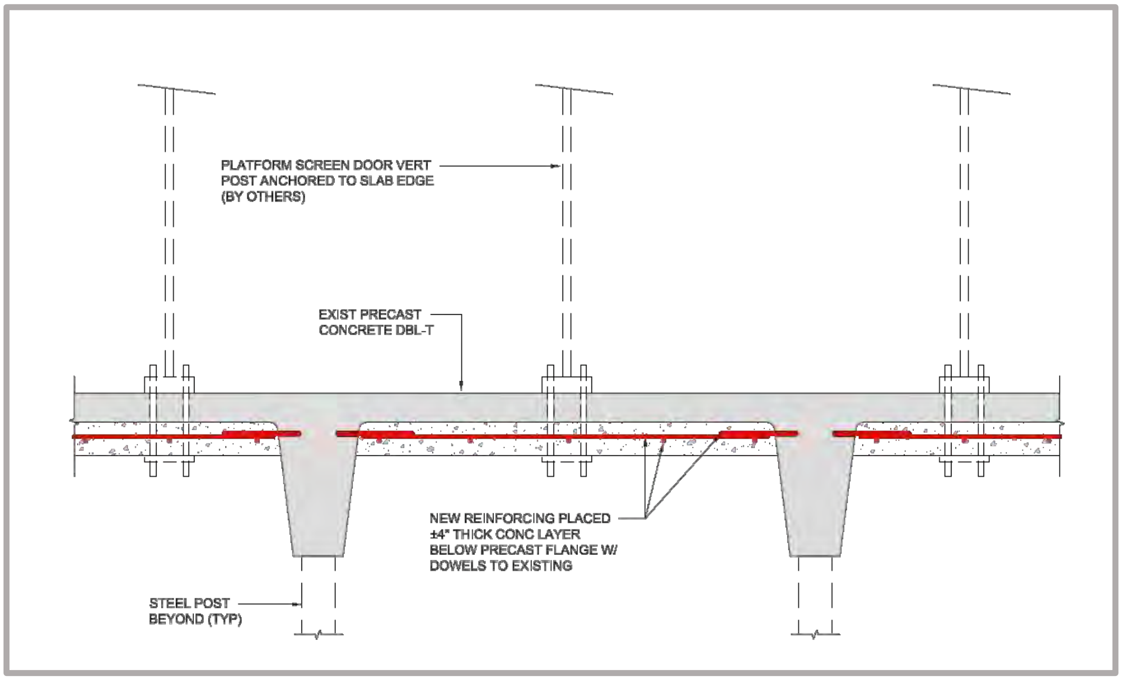

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5’ – 11” of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Franklin Avenue Shuttle

MTA/NYCT

July 25, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 7 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 10 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 2 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Franklin Avenue Shuttle

MTA/NYCT

July 25, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

STATION : FRANKLIN AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	175	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	**175**	**LF**

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	170	LF		
5	TOTAL LENGTH OF THE PLATFORM EDGE =	**170**	**LF**		
6	NUMBER OF TRAIN CARS ON THIS LINE =	**2**	**CARS**

131	Remove concrete platform edge				Previously done
132	Platform edge repair				Previously done
133	Drilling and cast in place treaded bar for receiving base plates for PSD framing; #4 per base plate				Previously done
134	Signal Work [Each 300' length is associated with one signal light]				
135	Disconnects				Not Applicable
136	Remove signal cables				Not Applicable
137	Remove conduit; Assuming 1"				Not Applicable
138	Install conduit in new position				Not Applicable
139	Install replacement cable; assumed single cable #12				Not Applicable
140	Re-commission / testing as required				Not Applicable
141	Engineering / Shop Drawings / Etc.				Not Applicable
142	Premium Time				Not Applicable
143

STATION : BOTANIC GARDEN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE =	174	LF		
5	LENGTH OF THE PLATFORM EDGE =	174	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**347**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**2**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	347	LF	7	2,431
14	Remove 5' wide section of 3" deep structural slab to platform edge	1,737	SF	12	20,840
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	35	CY	2,500	87,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	349	EA	25	8,734
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	349	EA	25	8,734
19	Cast in assemblies for PSD holding down bolts	128	EA	180	23,040
20	Polyethylene edge strip	347	LF	95	32,997
21	Provide sleeves for HV & LV wires	72	EA	110	7,920
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	347	LF	15	5,210
26	Remove existing platform tiles	347	LF	12	4,168
27	Sawcut existing topping concrete at perimeter of removal area	347	LF	5	1,737
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	2,084	SF	8	16,672
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance Platform width i.e. 7'-9" wide	140	SF	8	1,120
30	New Work				
31	New concrete topping to match existing	347	SF	15	5,210

STATION : BOTANIC GARDEN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	140	SF	15	2,100
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	96	LF	110	10,560
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (2 Cars x 4 Doors = 8 No. per platform)	16	EA	15,000	240,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #7 per Platform	14	EA	10,500	147,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	870	SF	750	652,523
61	Spare Parts - Approx. 10% of Material Cost	1	LS	67,891	67,891
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	16	EA	2,500	40,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Franklin Avenue Shuttle

25-Jul-19

STATION : BOTANIC GARDEN

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	347	LF	60	20,840
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	20	EA	12,000	240,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	2	EA	16,000	32,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	2	EA	15,000	30,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	48	EA	4,629	222,204
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	48	EA	5,566	267,147
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
