New York

SYSTEM-WIDE PLATFORM SCREEN DOOR FEASIBILITY STUDY – SUMMARY OF CONCLUSIONS

Background: Platform Screen Doors (PSDs), including all types of platform barrier systems, create a barrier between the trackway and passengers on the edge of platforms to reduce incidents of people coming into contact with trains. An investigation of this technology for use in the New York City Subway system was requested by NYCT.

Starting in October 2014, NYCT retained STV to follow up on earlier NYCT initiatives to improve customers' platform safety. STV was asked to begin a comprehensive background study which concluded in September 2016. The report provided NYCT with a greater understanding of the requirements for installing, operating, and maintaining various types of barrier systems including the control and communications systems new to NYCT that such technologies require. It became clear that installation of any of these systems would touch every division in NYCT.

Types of barrier systems in use by various transit agencies worldwide are:

1. Platform Screen Doors (PSD): full height
2. Automatic Platform Gates (APG): half height
3. Rope Platform Screen Doors (RPSD): vertically opening gate system

STV was tasked with a System-wide PSD Feasibility Study that was to address the challenges unique to the New York Subway system. Based upon the previous comprehensive background PSD study, continued discussions with NYCT, and conditions discovered during field surveys STV identified the challenges to installing PSDs in New York's century-old subway system. These challenges include but are not limited to:

- Platform width
- Distance of obstructions from platform edge (primarily staircases and columns)
- Americans with Disabilities Act (ADA) requirements
- Room/space availability for placement of door control equipment
- Availability of power to accommodate additional electrical load
- Multiple car classes with varying door opening positions
- Gaps between platform edges and trains
- Structural integrity of platform edges to support additional weight of PSDs
- Air flow dynamics within the station
- Other challenges included limited height, moving platform edges, grounding / isolation issues, etc.

Feasibility Study Scope and Schedule: In March 2017 STV began the study of all 472 subway stations to determine the feasibility of installing fixed railings, PSDs, APGs, and/or RPSDs at each station (nominally 472 stations) and every platform (more than 1200 platform edges). Working with NYCT, STV employed a hierarchical approach to assess the feasibility of installing the various barrier technologies via the development of screening criteria that defined 'fatal flaws' and/or critical cost factors. This hierarchical approach began with the broadest issues (for example, consistent train-door-alignment to train-door-alignment at platforms that share Lines), to less broad issues (for example, establishment of minimum space requirements for PSD control rooms or minimum clear space for APG/PSD components at the platform edge while maintaining code/ADA compliant egress widths) and to station specific issues (for example, the applications of these minimum space requirements at each station and platform). STV developed the screening criteria with NYCT project leadership, reviewed them with relevant stakeholders, and issued them shortly after the commencement of the study in a series of white papers.

Fixed railings were eliminated early in the study due to expressed concerns by NYCT OSS and MOW regarding the potential injury they could cause to customers due to door dragging incidents. RPSDs were also assessed and removed due to their very limited application world-wide, boarding and alighting issues, and other hazards they posed to customers.

Working with multiple survey teams, STV wrote reports for each station describing the application of the criteria. Where stations were deemed feasible, rough order of magnitude cost estimates were developed and included with the reports. Infeasible stations were documented as well, highlighting the reasons for infeasibility. Reports for each service line were issued together.

At the start of the study in March 2017, a schedule duration of 39 months was established with a completion date of June 2020; however, STV made significant efforts to expedite the completion of the study. Consequently, STV was able to complete the study in August 2019, 10 months ahead of schedule, following the issuance of the 22nd and final feasibility report.

Feasibility Results: Currently the NYCT Subway system features cars with three different door alignment profiles on the A Division and three on the B Division. The car types in each division are mixed among Subway Lines within their respective Divisions. The different spacing of doors on these cars makes installation of platform doors infeasible at most stations today. However, NYCT plans to complete the procurement of new rolling stock, per division, with nearly identical car geometries/door spacing, by 2033. Accordingly, STV's assessment assumes homogenized car classes, per division, by the year 2033.

PSD were deemed feasible at as few as **3%** and as many as **75%** of stations on a given Line. Overall system-wide feasibility is **27**%, or **128** of the **472** stations studied. Today, due to door misalignments, PSDs could only be implemented at 41 of the 128 stations, with implementation for the remainder being possible as car types (geometries/door spacings) in each Division/Line get progressively compatible by year 2033. The summary causes of infeasibility of stations are broken down in the table below:

REASONS FOR INFEASIBILITY		
Causative Factors	**Number of Infeasible Stations***	**Percentage of Infeasible Stations**
ADA Clearance	154	43%
Structural integrity of elevated Pre-cast Platforms	100	28%
Fleet Misalignment**	31	9%
Columns too close to edge	30	8%
No Space for PSD Equipment Room	21	6%
Gap Fillers	1	<1%

Above figures are for the year 2033 assuming procurement of new rolling stock occurs as currently scheduled.

*Some of the stations serving multiple Subway Lines may be feasible for one or more Lines but not all (on one or more platforms), therefore aggregating station counts for feasible and infeasible will exceed 472

**Car class compatibility will not be achieved on certain lines regardless of rolling stock changes due to dimensional differences between 8-car (M & G trains) and 10-car trains

Table 1 shows the total rough order of magnitude (ROM) costs including design, construction, Transit Authority Labor and Engineering Force Account costs for the **128** stations found feasible for installation of PSDs/APGs, as discussed above. The PDS (full height) option totals **$7.01B** and the APG (half height) option totals **$6.53B**, with approximate cumulative annual maintenance costs of **$119.16M** for either.

Table 1 – Total Approximate System-Wide Costs

No. of Stations	No. of Feasible Stations	% Feasibility	OPTION 1:* PSD (full height): Total Cost ($ billion)	OPTION 2:* APG (half height): Total Cost ($ billion)	Annual Maintenance Cost ($ million)
472	**128**	**27%**	**$7.01**	**$6.53**	**$119.16**

Table 2 (next page) shows the ROM cumulative loaded design, construction, NYCT Labor and Engineering Force Account costs for stations found feasible for installation of PSDs/APGs by Subway Lines/Service Routes. The cost for each Subway Line/Service Route includes duplicate costs that appear in a related Subway Line/Service Route that shares stations (for example, the Nos. 1, 2, & 3 routes). All cost estimates are based on 2018-19 dollars. Escalation costs out to possible year of award are not included and are expected to be around 4% per annum.

Table 2 – Approximate Costs Per Line						
Line/Service	**No. of Stations****	**No. Feasible**	**% Feasibility**	**OPTION 1*: PSD (full height) Total Cost ($ million)**	**OPTION 2*: APG (half height) Total Cost ($ million)**	**Annual Maintenance Cost ($ million)**
S (T. Sq.)	2	1	50.0%	$31.41	$27.23	$0.93
L	24	14	58.3%	$764.84	$605.43	$13.03
7	22	7	31.8%	$491.94	$445.86	$6.52
F	45	5	11.1%	$318.17	$250.72	$4.66
G	21	6	28.6%	$377.45	$288.83	$5.59
E	32	12	37.5%	$793.80	$614.28	$11.17
J Z	30	6	20.0%	$366.81	$267.83	$5.59
M	36	4	11.1%	$218.88	$175.58	$3.72
W	23	3	13.0%	$131.58	$153.50	$2.79
N	46	9	19.6%	$572.57	$501.93	$8.38
R	45	3	6.7%	$259.67	$201.95	$2.79
1	38	6	15.8%	$323.92	$258.36	$5.59
2	61	5	8.2%	$267.56	$213.61	$4.66
3	34	1	2.9%	$52.37	$42.32	$0.93
4	54	5	9.3%	$268.63	$215.21	$4.66
5	55	6	10.9%	$311.12	$257.47	$5.59
6	38	5	13.2%	$271.33	$215.16	$4.66
Q	34	8	23.5%	$443.67	$449.52	$7.45
S (Fkln. Ave.)	4	3	75.0%	$65.00	$58.12	$2.79
A /C	66	41	62.1%	$2,637.00	$2,214.32	$38.17
B	37	6	16.2%	$447.30	$349.21	$5.59
D	41	5	12.2%	$320.52	$250.59	$4.66

* Loaded estimated cost includes design, construction (+ 5% contingency), (+ 20% Engineering Force Account) & (+30% Transit Authority Labor)

** Some of the stations serving multiple subway lines may be feasible for one or more lines (on one or more platforms) but not necessarily all lines or platforms. Therefore, aggregating feasible and infeasible station counts will exceed 472 stations and overall cost totals from Table 2 will be more than the totals shown in Table 1.

Appendix D- Maintenance Cost Estimates
Appendix E- ROM Cost Estimates

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 38 newly evaluated stations, 32 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at the 1-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 16% of the '1' Line stations. Total implementation cost would be \$164.0M for APGs and \$205.7M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of \$931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 6 feasible stations, the aggregate annual maintenance cost would be \$5.6M.

Summary Table

(16% Feasible 6/ 38)

1.0 Station Assessments

1.01 – MR 293 | 242nd Street / Van Cortlandt Park Station

Summary: *242nd Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

242nd Street Station is an elevated station consisting of a center / island platform and two side platforms that are not in use. The platform structure is precast concrete. The width of the center platform is 14'-0" throughout. The platform is straight with one row of centered columns supporting the station canopy. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
242nd Street Station

***Figure 2** – Precast Slabs*
242nd Street Station

1.02 – MR 294 | 238th Street Station

Summary: *238th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The 238th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 8'-3" to 14'-0". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

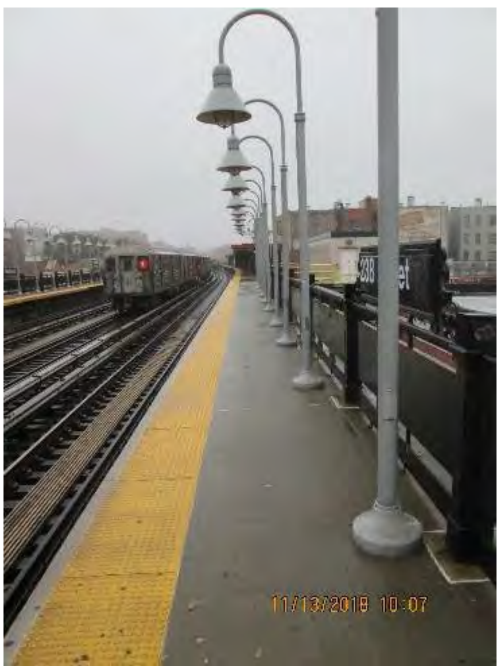

Figure 1 *– General Station Condition*
238th Street Station

Figure 2 *– Precast Slab*
238th Street Station

1.03 – MR 295 | 231st Street Station

Summary: *231st Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

231st Street Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 14'-6", narrowing to 8'-0" at the ends. The platforms are straight with a single row of columns supporting their respective station canopies. See figure 1 & 2 for reference.

Figure 1 *– Overall view*
231st Street Station

Figure 2 *– Precast concrete platforms*
231st Street Station

1.04 – MR 296 | 225th Street Station

Summary: *225th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

225th Street Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 14'-8", narrowing to 7'-0" at the ends. The platforms are straight with a single row of columns supporting their respective station canopies. See figure 1 & 2 for reference.

Figure 1 *– Overall view*
225th Street Station

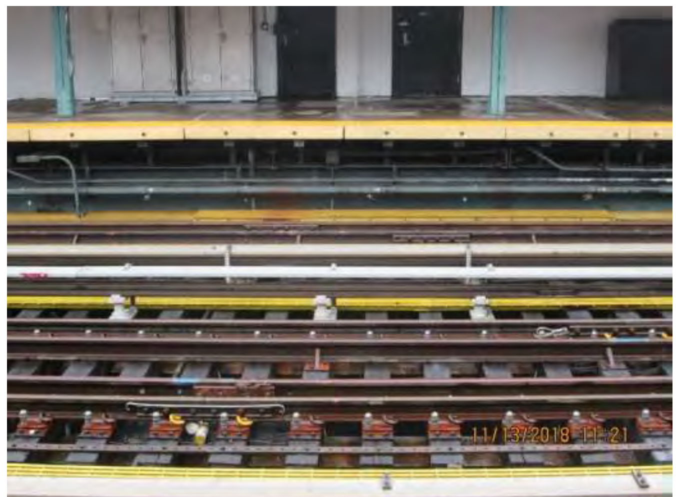

Figure 2 *– Precast concrete platforms*
225th Street Station

1.05 – MR 297 | 215th Street Station

Summary: *215th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

215th Street Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 14'-0", narrowing to 7'-0" at the ends. The platforms are straight with a single row of columns supporting their respective station canopies. See figure 1 & 2 for reference.

Figure 1 *– Overall view*
215th Street Station

Figure 2 *– Precast concrete platforms*
215th Street Station

1.06 – MR 298 | 207th Street Station

Summary: *207th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

207th Street Station is an elevated station with two straight side platforms. The platform structures are precast concrete. The width of the platforms is approximately 14'-0", narrowing to 7'-0" at the ends. The platforms are straight with a single row of columns supporting their respective station canopies. See figure 1 & 2 for reference.

***Figure 1** – Overall view*
207th Street Station

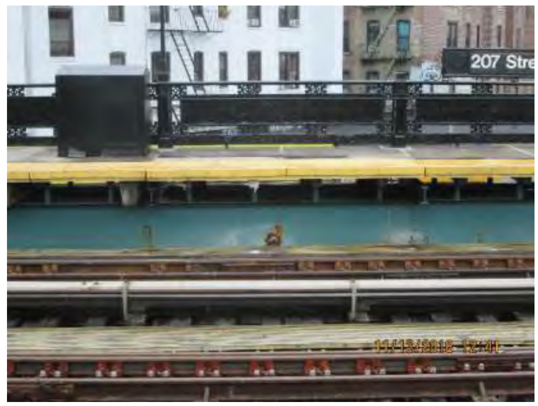

***Figure 2** – Precast concrete platforms*
207th Street Station

1.07 – MR 299 | Dyckman Street Station

Summary: *Dyckman Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Dyckman Street Station is an elevated / on-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located along approximately one-third of the platforms at the canopy. Column faces measure approximately 4'-2" from the platform edge. The platform width is approximately 13'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-0" x 7'-0".

Track Layout

Tracks are nearly tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the last five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system.

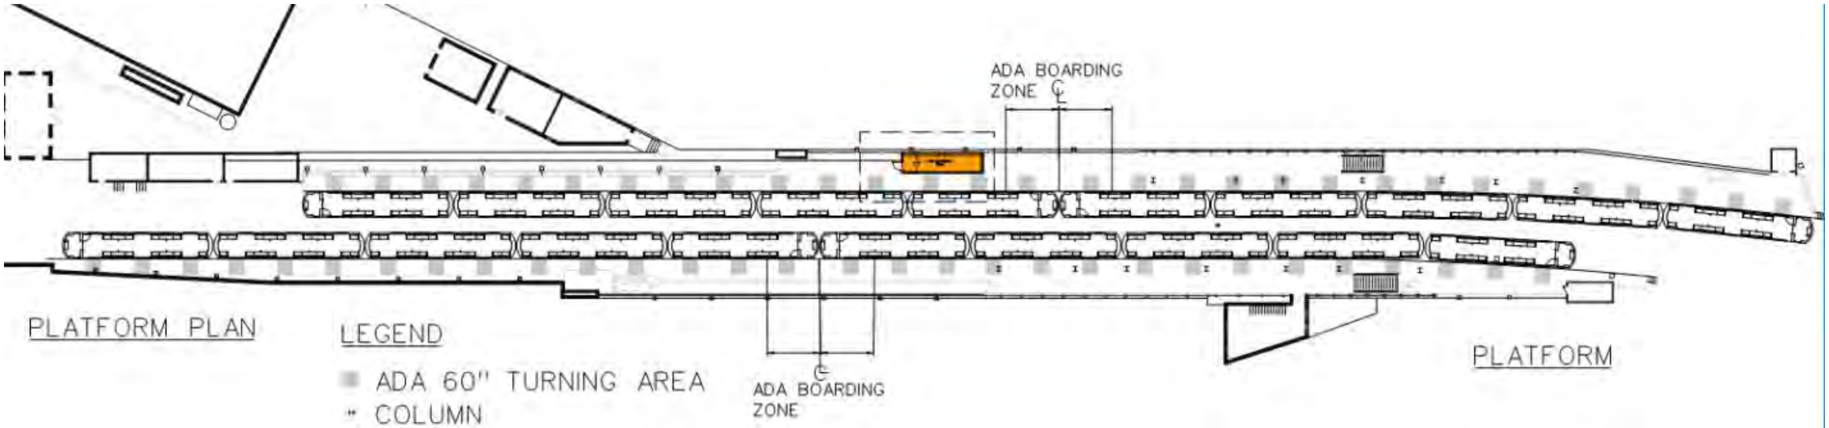

Figure 1 *– Overall Station Plan*
Dyckman Street Station

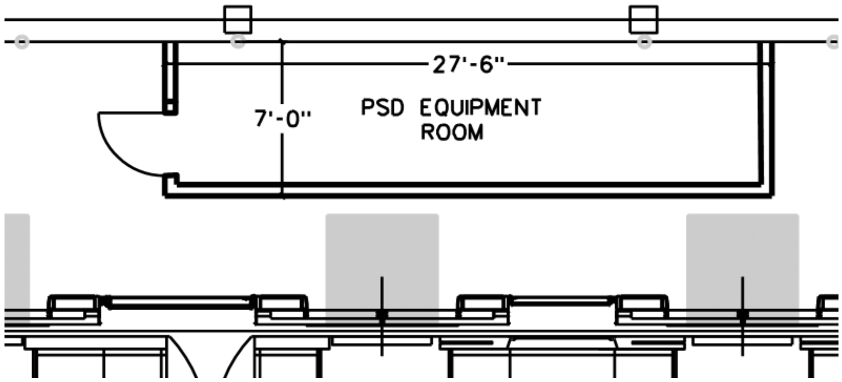

Figure 2 *– PSD Equipment Room 1 Detail*
Dyckman Street Station

Figure 3 *– Typical platform view*
Dyckman Street Station

Platform obstructions within 5' of edge:

- Northbound: Columns
- Southbound: Columns

These obstructions do not present an impediment to the installation of PSDs.

Lighting:
Existing lighting: At the platform canopies there are linear florescent fixtures mounted parallel to the platform edge. Where no canopy exists, lighting is provided by pole-mounted fixtures along the back wall. No lighting reconfiguration will be required as a result of a PSD installation.

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Dyckman Street Nagle Ave.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	61.2
Apparent Power (kVA)	76.5
Station Peak Demand Load, Max Current, (A)	213.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	371
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	747 (=1200*0.8-213)
Is Electrical Service Adequate?	**Yes**
Notes	Station's current spare capacity is 747A. PSD load is 158 A. Therefore there is spare capacity in Normal Service SW. Similarly, there is spare on Reserve service also since peak deman on Reserve is 46 KW, less that that of Normal load

Table 1. *Normal Service Power Capacity Analysis*

Station
Power Capacity Analysis (reserve service)

Station Name	Dyckman Street Nagle Ave.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	46.0
Apparent Power (kVA)	57.5
Station Peak Demand Load, Max Current, (A)	160.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	318
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	642 (=1200*0.8 - 318)
Is Electrical Service Adequate?	**Yes**
Notes	Spare capacity analysis for Reserve service.

***Table 2**. Reserve Service Power Capacity Analysis*

Historic Restrictions:
The southern end of the Dyckman Street station is a historically designated property. As such, design will require review by the New York State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.4M to install APGs and $34.0M to install PSDs (See Appendix E)

1.08 – MR 300 | 191st Street Station

Summary: *191st Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

191st Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 2'-2" from the platform edge. The southbound platform width is approximately 12'-4" throughout. The northbound platform width is approximately 12'-2 throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting

Equipment Room

The equipment room could be located at the mezzanine flush to the wall (see **Figure 1, Figure 2**). The proposed room dimension is 27'-0" x 7-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey information was not ascertainable at the time of drafting this report, where on a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair. Any platform edge with a rating above 2.5 requires platform rehabilitation regardless of if an APG or PSD system is utilized.

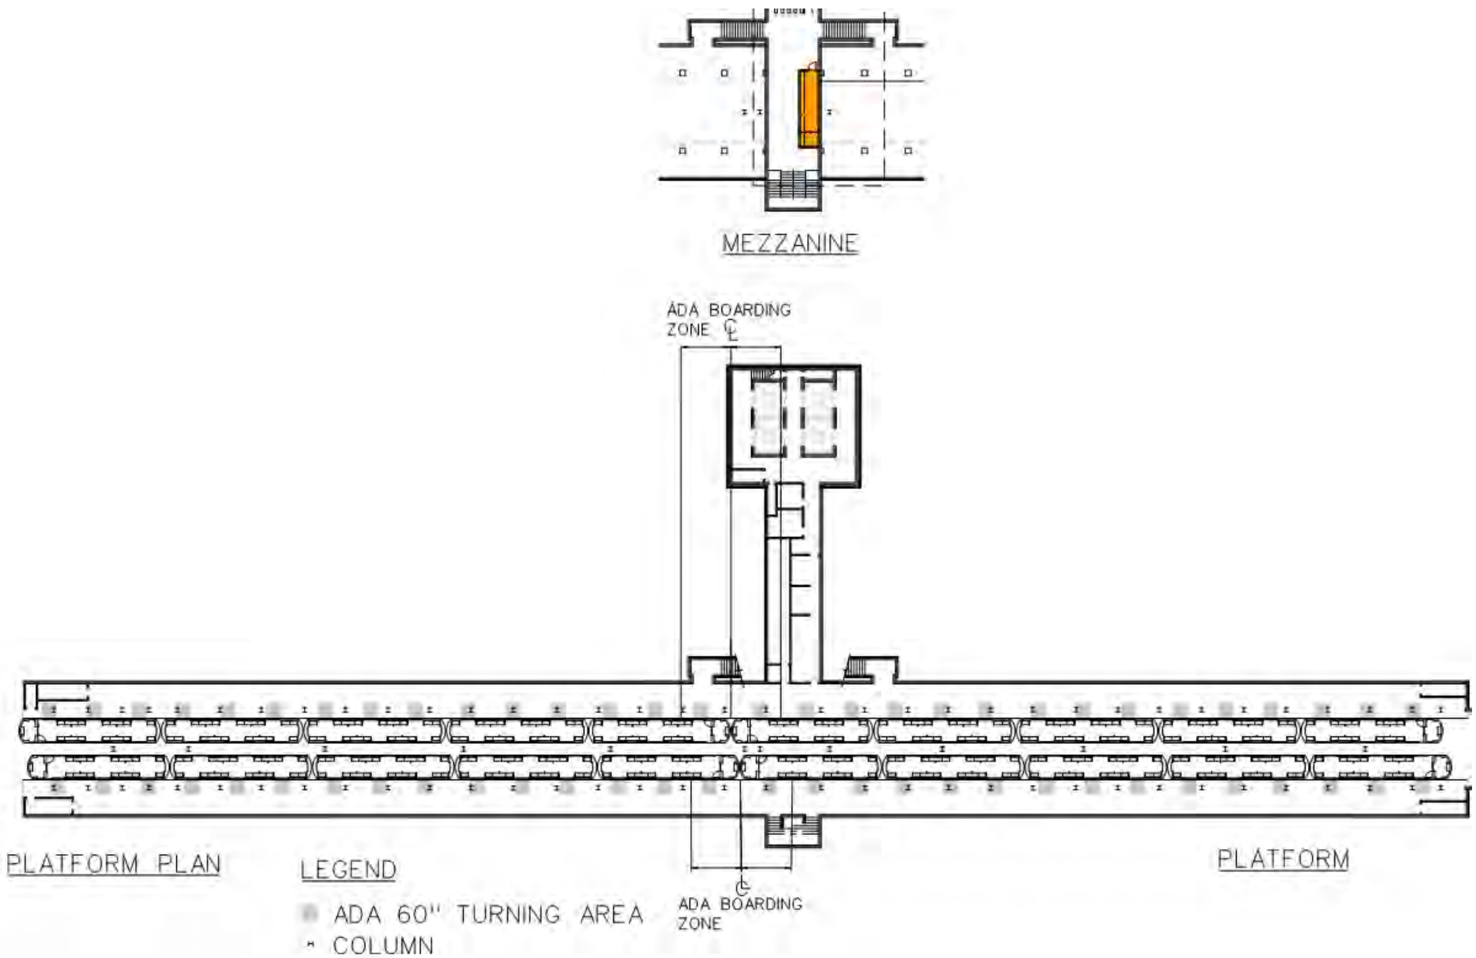

***Figure 1** – Overall Station Plan*
191st Street Station

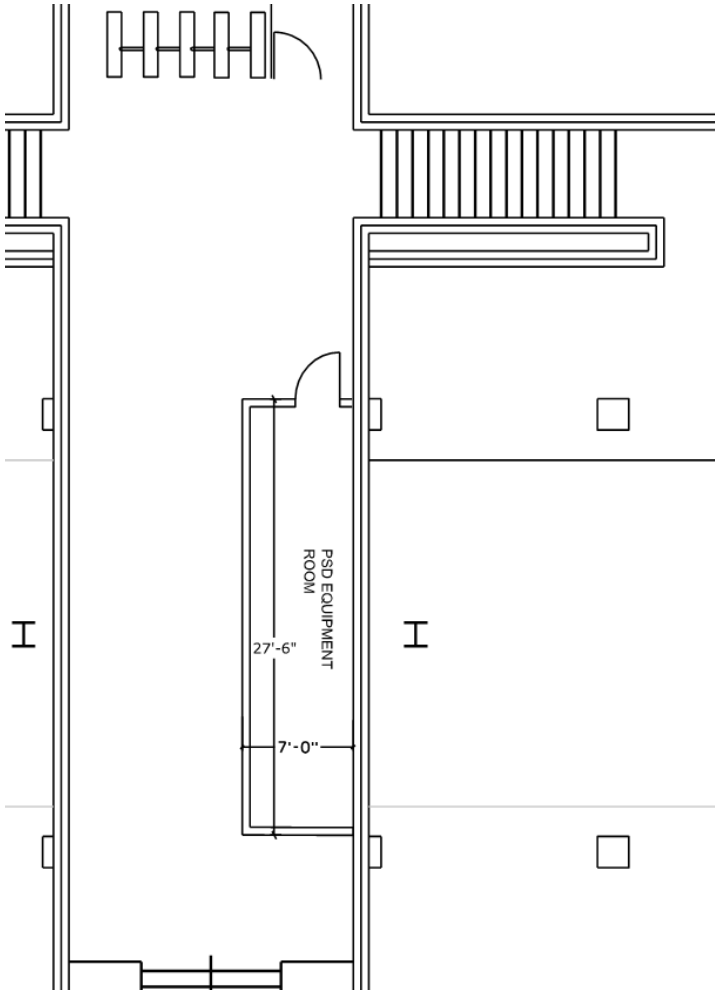

***Figure 2** – PSD Equipment Room Detail*
191st Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge on the inside face of the columns. No lighting re-configuration will be required as a result of a PSD installation.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Station
Power Capacity Analysis (normal service)

Station Name	191st Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	104.0
Apparent Power (kVA)	130.0
Station Peak Demand Load, Max Current, (A)	361.1
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	519
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200 AF
Service Spare Capacity, (A)	441 (=1200*0.8 - 519)
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity based on Con Ed deman loads & service one line diagram.

Station
Power Capacity Analysis (reserve service)

Station Name	191st Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	16.0
Apparent Power (kVA)	20.0
Station Peak Demand Load, Max Current, (A)	56.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	214
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	746
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity based on Con Ed deman loads & service one line diagram.

Table 2. Reserve Service Power Capacity Analysis

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $27.0M to install APGs and $33.6M to install PSDs (See Appendix E)

Figure 3 *– Typical Platform View*
191st Street Station

1.09 – MR 301 | 181st Street Station

***Summary:** 181st Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

The 181st Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 12'-10' to 13'-0". The corridor width at this station's staircases is 48". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. Furthermore, there is a column adjacent to the staircase measuring 40" from the platform edge, the implementation of a platform edge barrier would reduce this width to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

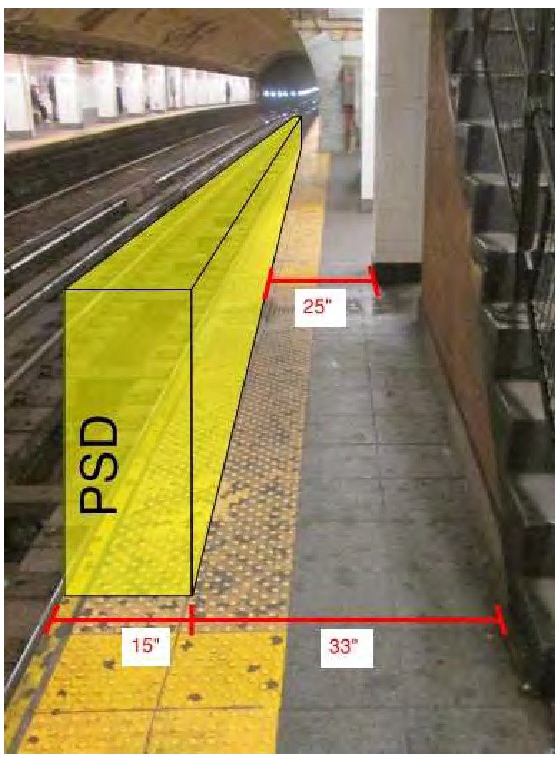

***Figure 1** – Non-compliant ADA condition*
181st Street Station

1.10 – MR 302 | 168th Street Station

Summary: *168th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 15" (see figure 1.*

Description

The 168th Street Station is a below-grade station consisting of two side platforms. The platform widths are approximately 12-6" throughout. The platforms are straight with one rows of columns at 2'-6" from edge of platform. At the south end of the northbound platform, the columns flanking station refuse room are 30" from the platform edge. The implementation of a platform edge barrier would reduce this width to 15" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

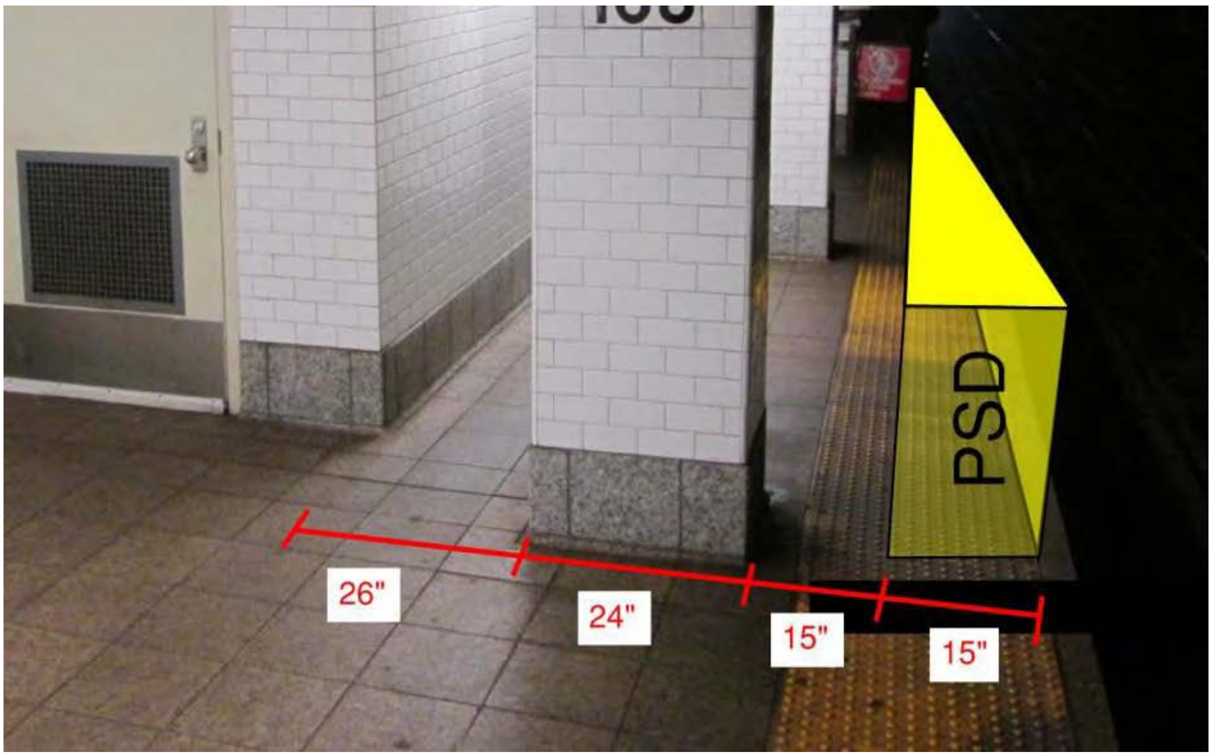

Figure 1 *– Non-compliant ADA condition*
168tht Street Station

1.11 – MR 303 | 157th Street Station

Summary: *157th Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

157th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 14" from the platform edge, which would prevent a continuous 15"–wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 1'-2" from the edge*
157th Street Station

1.12 – MR 304 | 145th Street Station

Summary: *145th Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

145th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 14" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 1'-2" from the edge*
145th Street Station

1.13 – MR 305 | 137th Street / City College Station

Summary: *137th Street is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

137th Street/City College Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 14" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 1'-2" from the edge*
137th Street Station

1.14 – MR 306 | 125th Street Station

Summary: *125th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The 125th Street Station is an elevated station with two straight side platforms. The platform structures are precast concrete. There are two staircases at the center of each platform. The platform widths are approximately 12'-8 throughout. The platform is straight with one row of centered columns supporting the station canopy. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
125th Street Station

Figure 2 *– Precast Slab*
125th Street Station

1.15 – MR 307 | 116th Street Station

Summary: *116th Street Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

116th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
116th Street Station

1.16 – MR 308 | 110th Street / Cathedral Parkway Station

Summary: *110th Street Station is not feasible for both APGs and PSDs as the columns which are located 16” from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

110th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16” from the platform edge. While this dimension allows for the 15”-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
110th Street Station

1.17 – MR 309 | 103rd Street Station

Summary: *103rd Street Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

103rd Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge, which would prevent a continuous 15"-wide barrier from being installed. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
103rd Street

1.18 – MR 310 | 96th Street Station

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 96th Street Station is a below-grade station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 13'-6' to 17'-8". The corridor width at this station's elevators is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
96th Street Station

1.19 – MR 311 | 86th Street Station

Summary: *86th Street Station Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

86th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

.

Figure 1 – *Column 16" from the edge*
86th Street Station

1.20 – MR 312 | 79th Street Station

Summary: *79th Street Station is not feasible for both APGs and PSDs as the columns which are located 15" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

79th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 15" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1 –** Column 16" from the edge*
79th Street Station

1.21 – MR 313 | 72nd Street Station

Summary: *72nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at five platform stairs as the remaining width would be 15" (see figure 1).*

Description

The 72nd Street Station is a below-grade station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 15'-6". The corridor width at this platform stairs is 30". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
72nd Street Station

1.22 – MR 314 | 66th Street / Lincoln Center Station

Summary: *66th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

66th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
66th Street Station

1.23 – MR 315 | 59th Street / Columbus Circle Station

Summary: *59th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

59th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

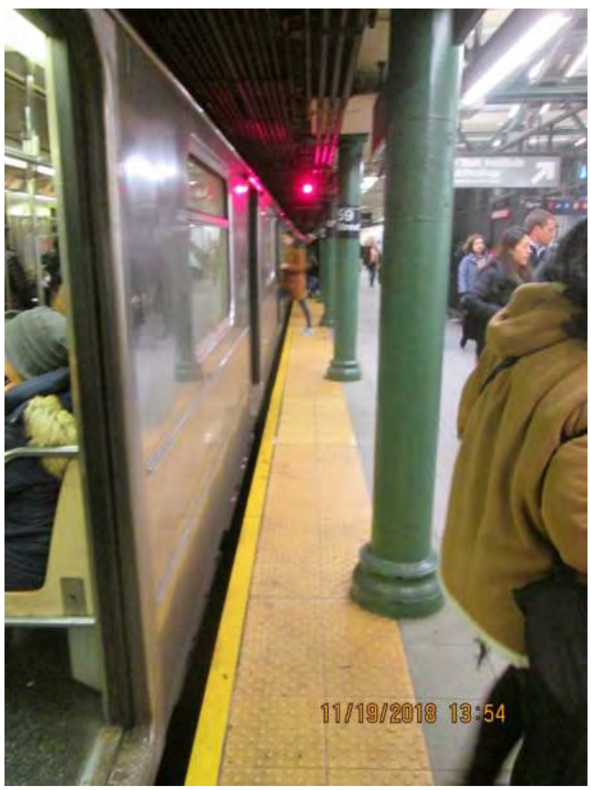

Figure 1 – *Column 18" from the edge*
59th Street Station

1.24 – MR 316 | 50th Street Station

Summary: *50th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

50th Street Station is not feasible for both APGs and *PSDs* due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
50th Street Station

1.25 – MR 317 | 42nd Street / Times Square Station

Summary: *42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the south end of the platform as the remaining width would be 27" (see figure 1).*

Description

The 42nd Street Station is an underground station consisting of two center / island platforms. The platforms are approximately 21'-2" wide throughout. At the southern end of the northbound platform there are 42" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
42nd Street Station

1.26 – MR 318 | 34th Street / Penn Station

Summary: *34th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 27" (see figure 1).*

Description

The 34th Street Station is an underground station consisting one center / island platform. The platforms are approximately 7' wide throughout. At the north end of the northbound platform there is 42" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
34th Street Station

1.27 – MR 319 | 28th Street Station

Summary: *28th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at south end of the southbound platform as the remaining width would be 33" (see figure 1).*

Description

The 28th Street Station is a below-grade station with two platforms. The platform structures are cast-in-place concrete. The width of the platforms are approximately 11'-10". The implementation of a platform edge barrier would reduce this width at the south end of the southbound platform below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

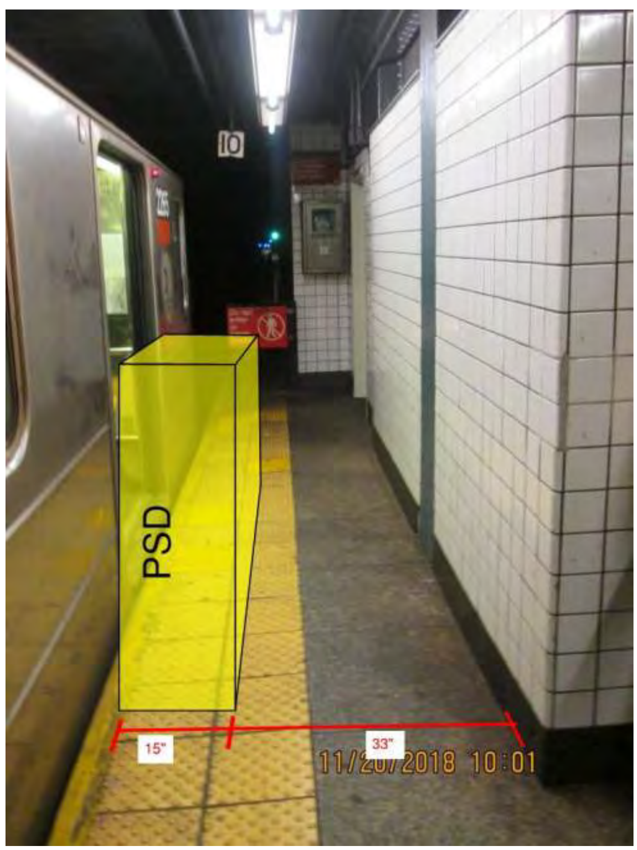

Figure 1 *– Non-Compliant ADA condition*
28th Street Station

1.28 – MR 320 | 23rd Street Station

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-10" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-10' to 11'-10".

Platform width at the ends of the northbound & southbound platform are 5'-10" or 70". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

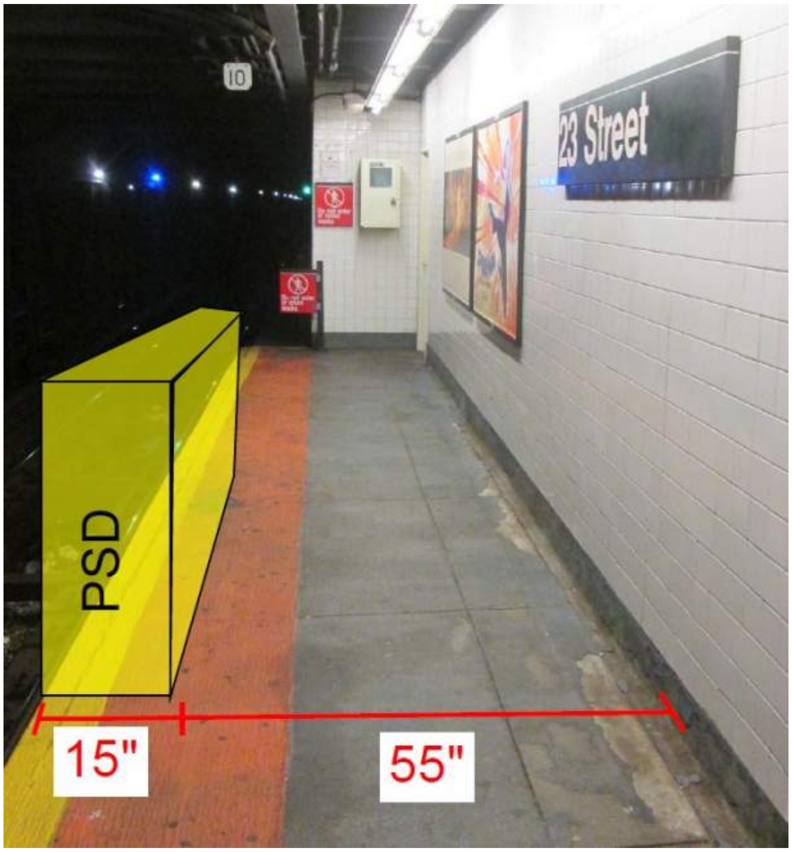

***Figure 1** – Non-Compliant code condition*
23rd Street Station

1.29 – MR 321 | 18th Street Station

Summary: *18th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 5'-0"" (see figure 1).*

Description

18th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 11'-6".

Platform width at the southern end of the southbound platform is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant code condition*
18th Street Station

1.30 – MR 322 | 14th Street Station

Summary: *14th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-0"" (see figure 1).*

Description

14th Street Station is a below-grade station with two straight center/ island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 19'-4".

Platform width at the southern end of both platforms is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant code condition*
14th Street Station

Table of Contents

1.31 – MR 323 | Christopher Street Station

Summary: *Christopher Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Christopher Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns on each platform.

Due to the extremely limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar.

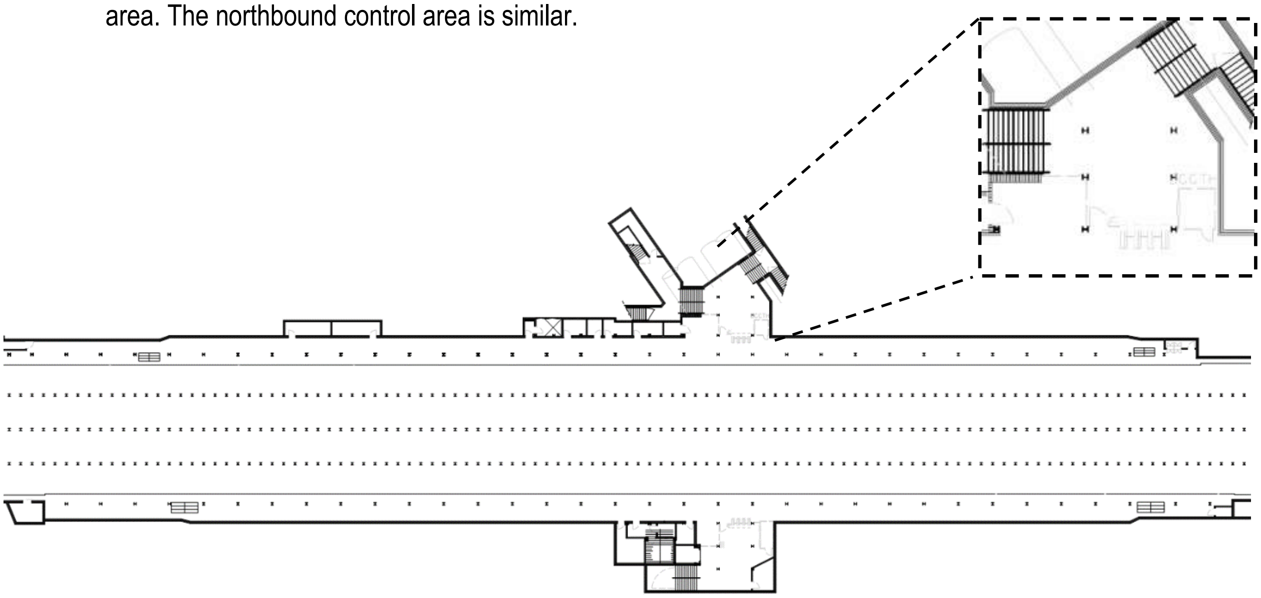

Figure 1 *– Congested/Narrow Station Plan*
Christopher Street Station

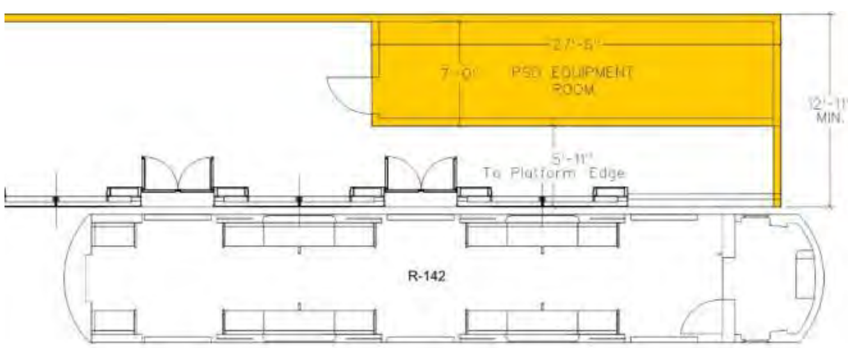

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.32 – MR 324 | Houston Street Station

Summary: *Houston Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Houston Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 12-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

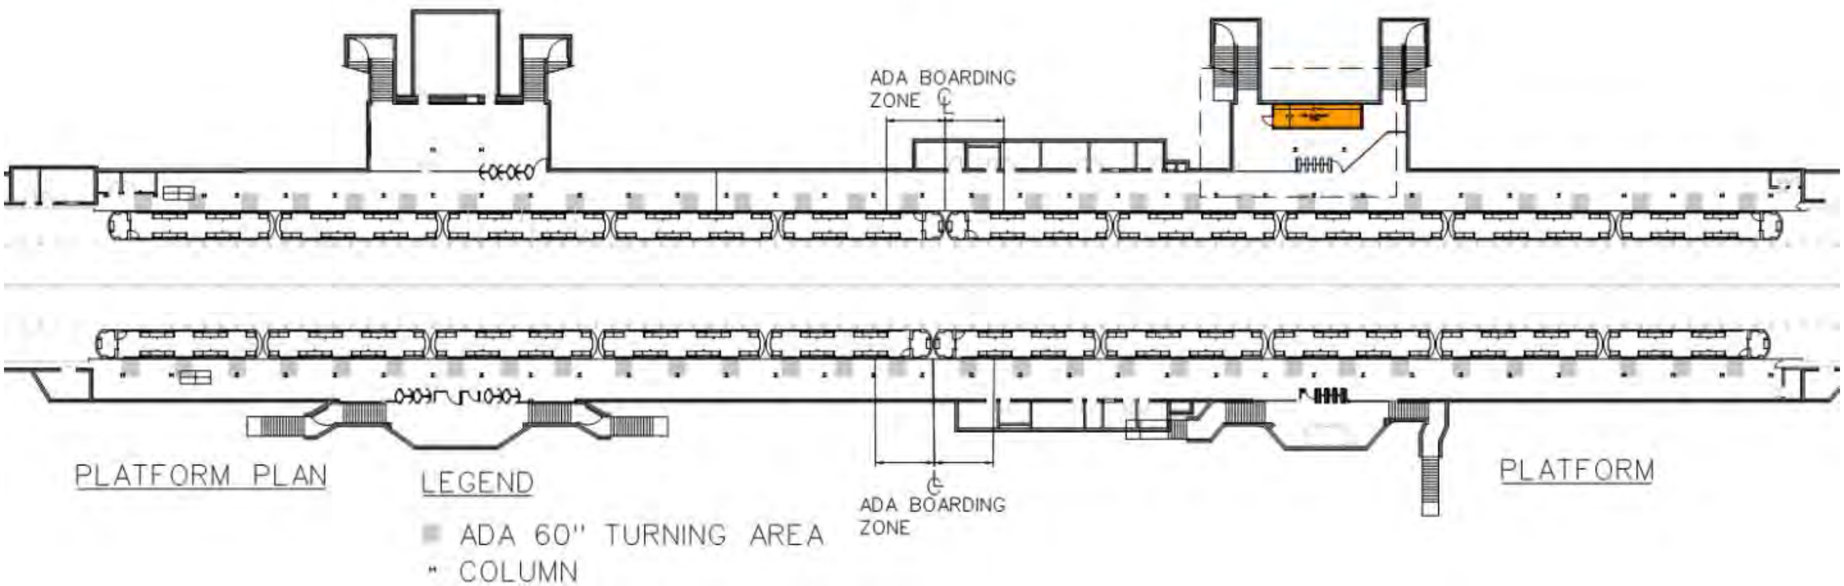

Figure 1 *– Overall Station Plan*
Houston Street Station

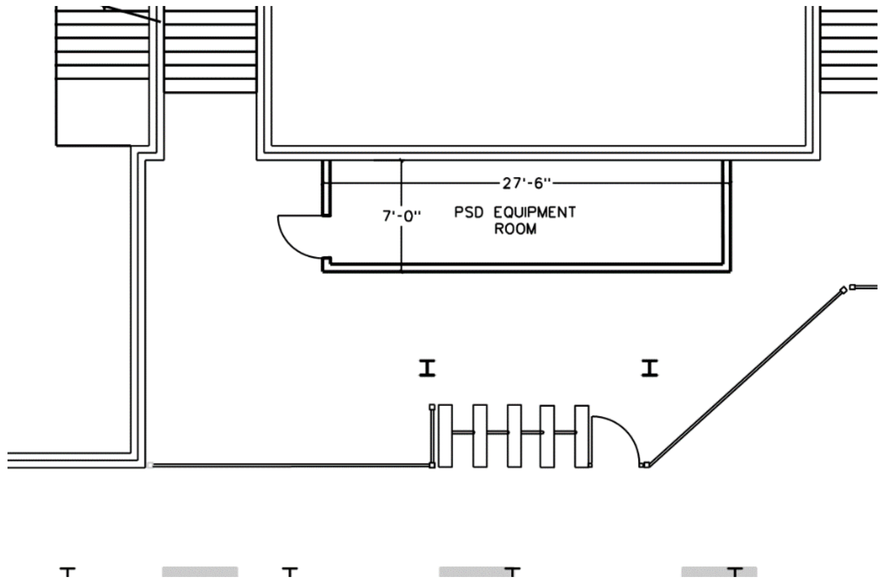

Figure 2 *– PSD Equipment Room 1 Detail*
Houston Street Station

Figure 3 *– Typical platform view*
Houston Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Houston Street Varick St.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	40.8
Apparent Power (kVA)	51.0
Station Peak Demand Load, Max Current, (A)	141.7
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	299
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	341 (=800*0.8 - 299)
Is Electrical Service Adequate?	**Yes**
Notes	Info based on "Electrical Distribution Room Wiring diagram" and photos.

Notes	Info based on "Electrical Distribution Room Wiring diagram" and photos.

Table 2. Reserve Service Power Capacity Analysis

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.2M to install APGs and $34.2M to install PSDs (See Appendix E)

1.33 – MR 325 | Canal Street Station

Summary: *Canal Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Canal Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 12-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the abandoned passageway at the south end of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey information was not ascertainable at the time of drafting this report, where on a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair. Any platform edge with a rating above 2.5 requires platform rehabilitation regardless of if an APG or PSD system is utilized.

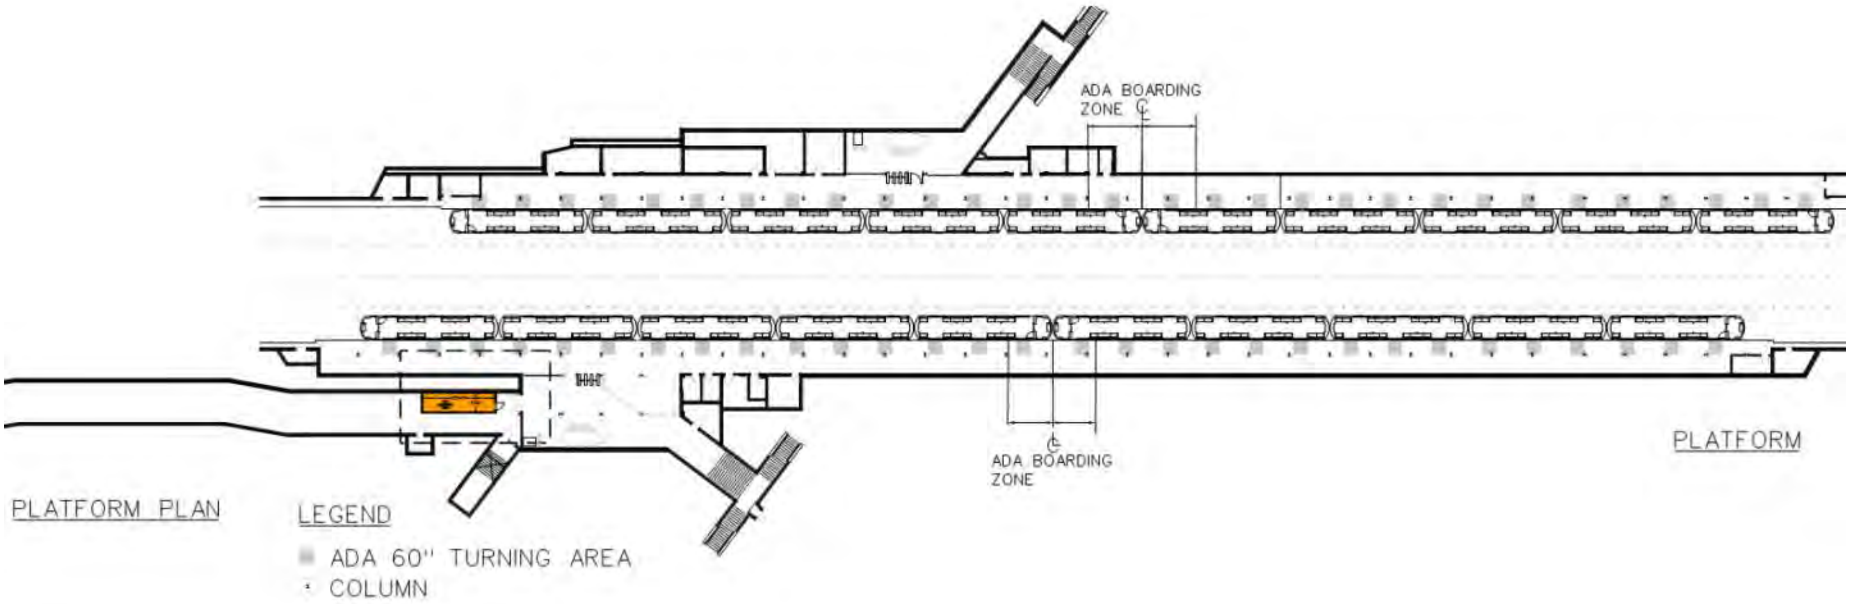

***Figure 1** – Overall Station Plan*
Canal Street Station

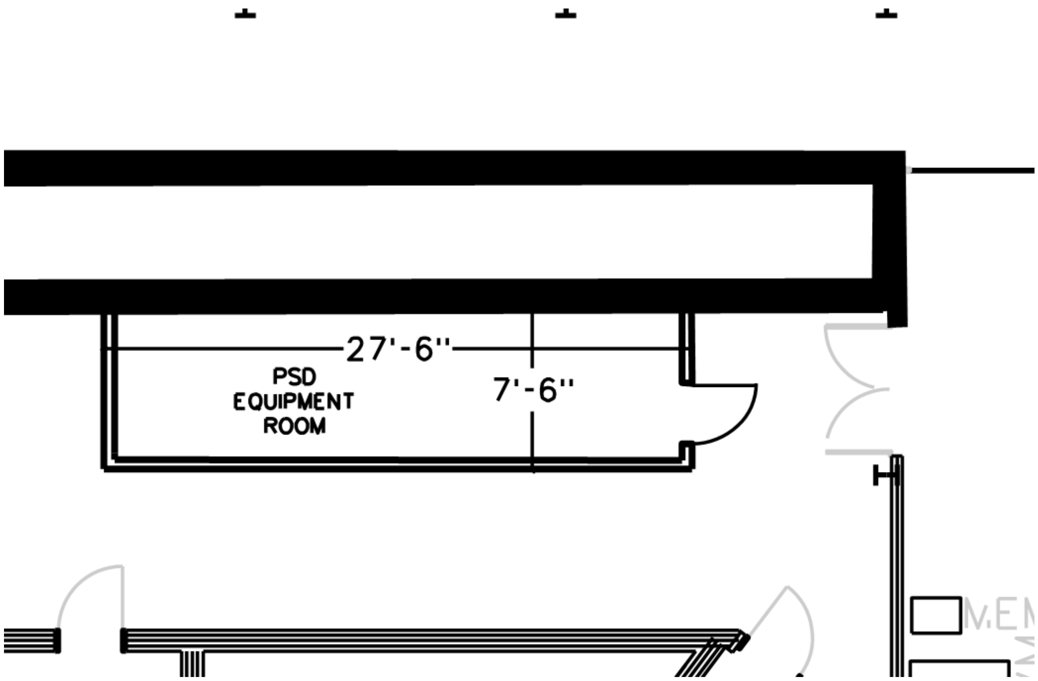

Figure 2 – PSD Equipment Room 1 Detail
Canal Street Station

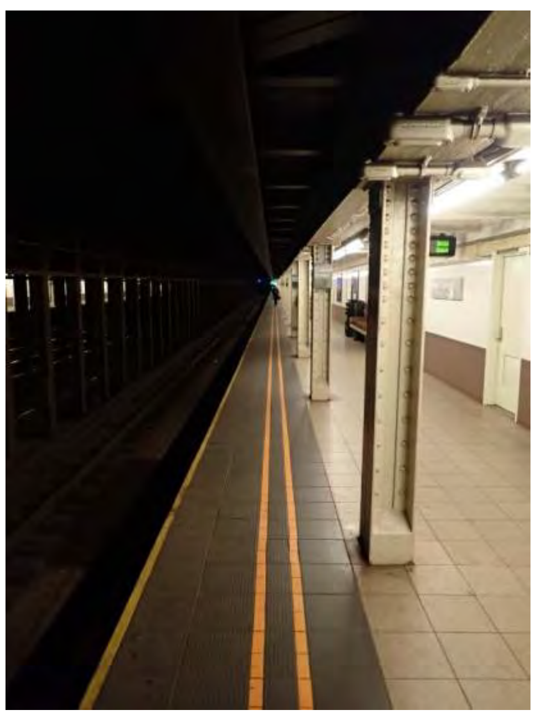

Figure 3 – Typical platform view
Canal Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge on the inside face of the columns. No lighting re-configuration will be required as a result of a PSD installation.

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Canal Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	0.0
Apparent Power (kVA)	0.0
Station Peak Demand Load, Max Current, (A)	0.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	158
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	482 (= 800*0.8 - 158)
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on photos. Only partial one line diagram (for tunnel lighting) is available. Also the above capacity is based on zero KW demand for Normal power submitted by Con Ed.

***Table 1**. Normal Service Power Capacity Analysis*

Station
Power Capacity Analysis (reserve service)

Station Name	Canal Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	37.2
Apparent Power (kVA)	46.5
Station Peak Demand Load, Max Current, (A)	130.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	288
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	352 (= 800*0.8 - 288)
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on photos. Only partial one line diagram (for tunnel lighting) is available. Also the above capacity is based on demand KW for Reserve power. Normal demand report shows all zeros, suggesting all power has been supplied by Reserve service.

***Table 2**. Reserve Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $35.3M to install PSDs (See Appendix E)

1.34 – MR 326 | Franklin Street Station

Summary: *Franklin Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Franklin Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 11-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey information was not ascertainable at the time of drafting this report, where on a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair. Any platform edge with a rating above 2.5 requires platform rehabilitation regardless of if an APG or PSD system is utilized.

Is Electrical Service Adequate?	**Yes**
Notes	Normal demand information available. No reserve service.

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.1M to install APGs and $33.7M to install PSDs (See Appendix E)

1.35 – MR 327 | Chambers Street Station

Summary: *Chambers Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 15" (see figure 1).*

Description

The Chambers Street Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 17'-2". The corridor width at the southern end of the southbound platform is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
Chambers Street Station

1.36 – MR 328 | Cortlandt Street / WTC Station

Summary: *Cortlandt Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Power adequacy could not be ascertained for this station as a history of meter readings was not available for analysis due to the seventeen-year closure of the station. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Cortlandt Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 3'-2" from the platform edge. The platform widths approximately range from 10-4" to 22'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are nearly tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past five years as part of the station reconstruction project. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system.

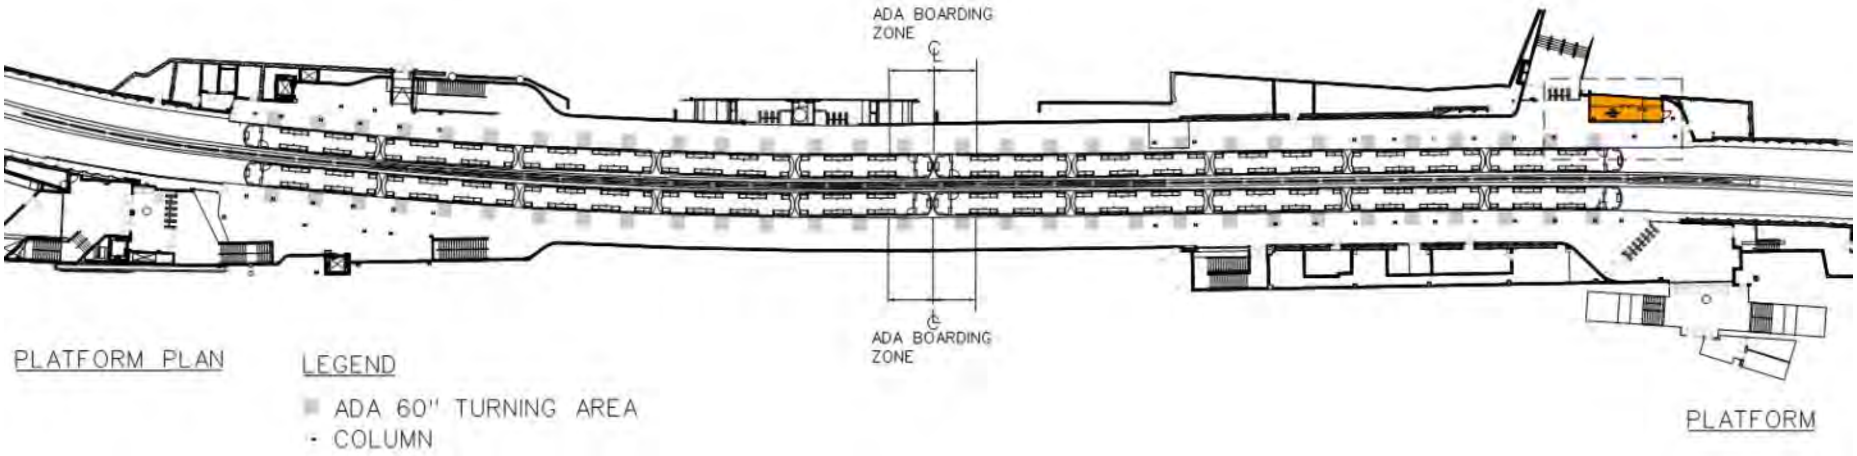

Figure 1 *– Overall Station Plan*

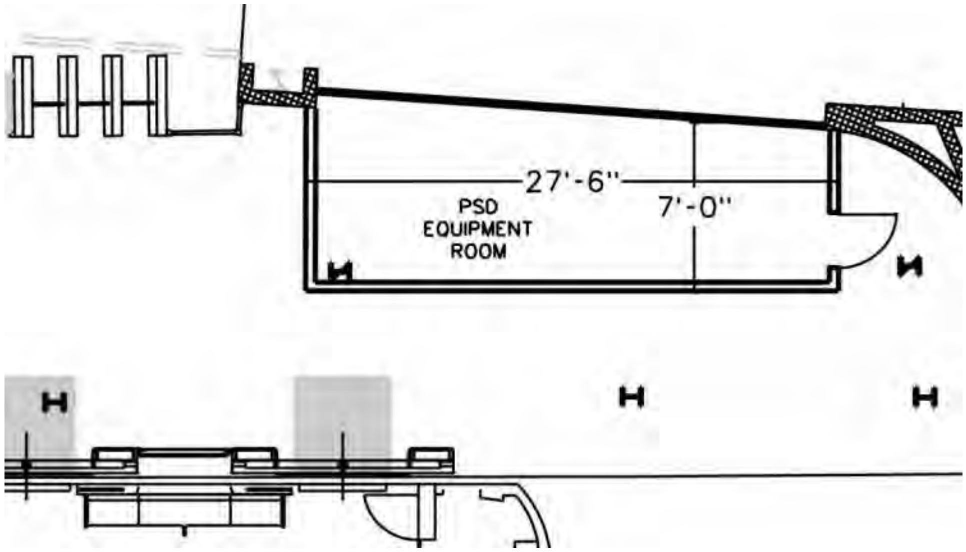

Figure 2 *– PSD Equipment Room 1 Detail*
Cortlandt Street Station

Figure 3 *– Typical platform view*
Cortlandt Street Station

Platform obstructions within 5' of edge:

- Columns at north and south ends of both platforms

These obstructions do not present an impediment to the installation of PSDs.

Lighting:
Existing lighting: Throughout both platforms, linear LED lighting perpendicular to the platform edge. Installation of APG/PSD will not affect the existing lighting configuration.

Power:
A history of meter readings were not available for analysis due to the seventeen-year closure of the station. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $34.8M to install PSDs (See Appendix E)

1.37 – MR 329 | Rector Street Station

***Summary:** Rector Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room, and due to non-compliant ADA dimensions at the northbound platform.*

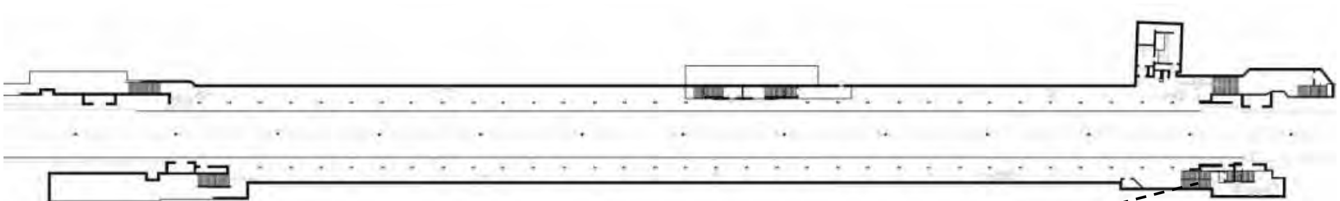
Description

Rector Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns on each platform.

Due to the extremely limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room. The width of the existing platform is only 11'-8". Figure 1, below, demonstrates the lack of available space within the northbound control area. The other control areas / exits are similar.

In addition to the above limitation, the installation of PSDs will create constrained dimensions. The width at the northern end of the northbound platform is 38". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 3 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.



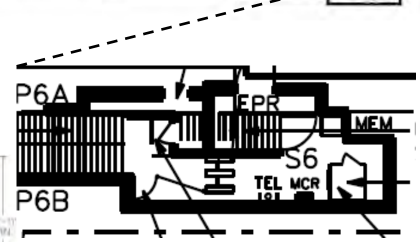


***Figure 1** – Congested/Narrow Station Plan*
Rector Street Station

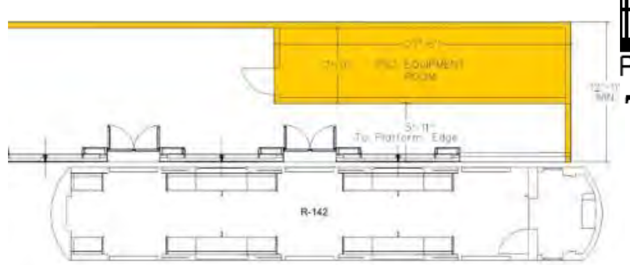

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

Figure 3– *Non-compliant ADA zone at north end of northbound platform*

1.38 – MR 330 | South Ferry Station

Summary: *South Ferry Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the various areas along each platform as the existing width is 4'-8" (see figure 1).*

Description

South Ferry Station is a below-grade station with one center/island platform. The platform structures are cast-in-place concrete. There is a single row of columns at the center of the platform.

Platform width adjacent to various facility rooms on the platform is 4'-8". With the installation of PSDs, this dimension will be reduced to 41" or less*. Our station egress analysis (See Appendix C) finds that 5'-11" is a minimum platform width which will not impede egress via emergency exit doors with an installed PSD system. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for <u>Tier 2 Stations'</u> screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for <u>Tier 3 Stations</u> will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	Comments
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

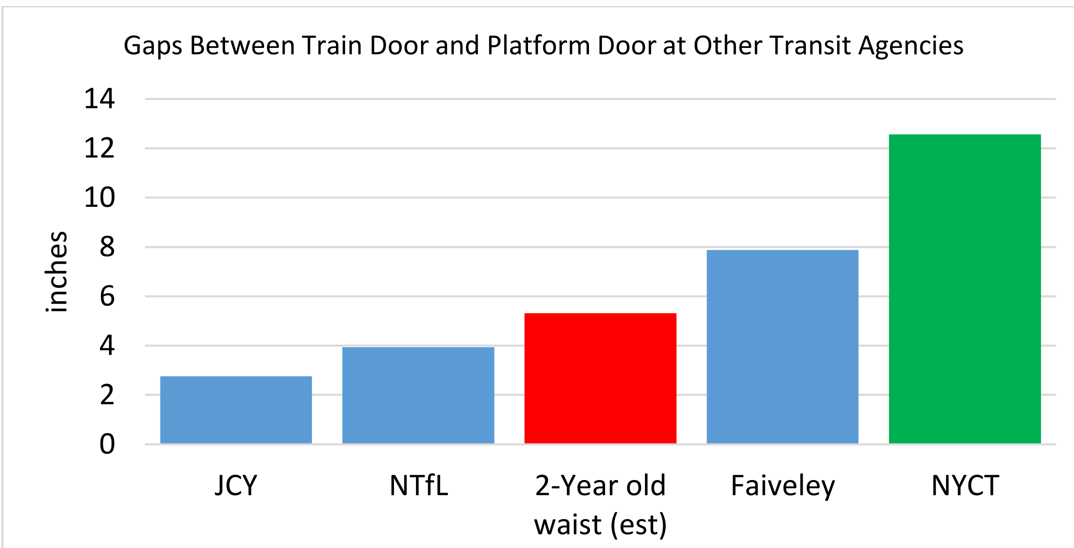

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

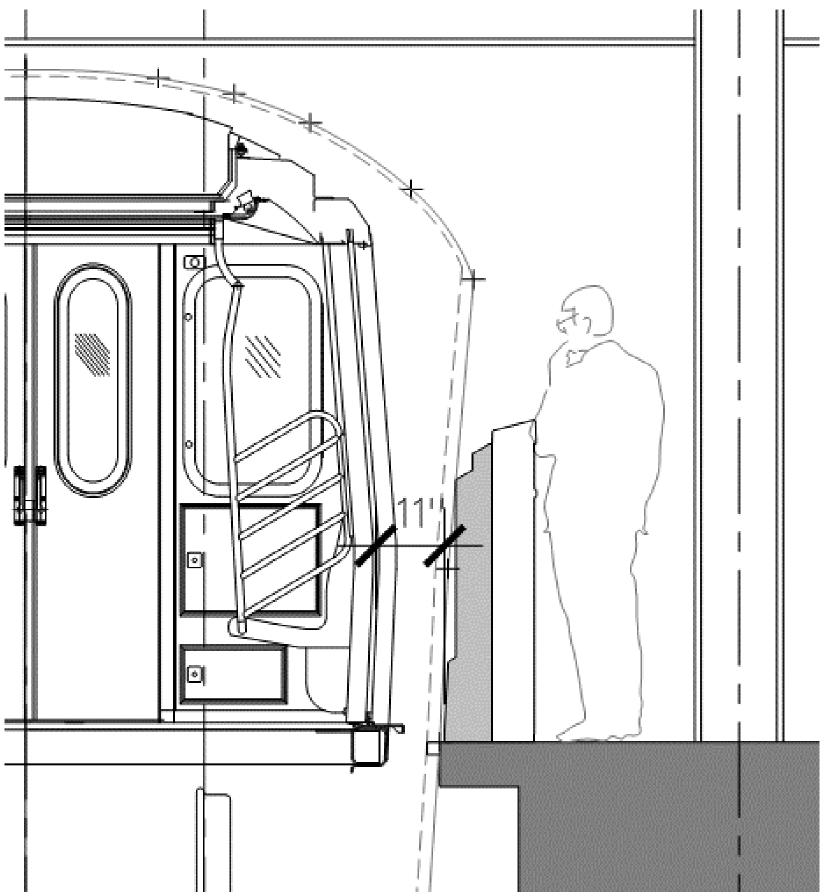

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

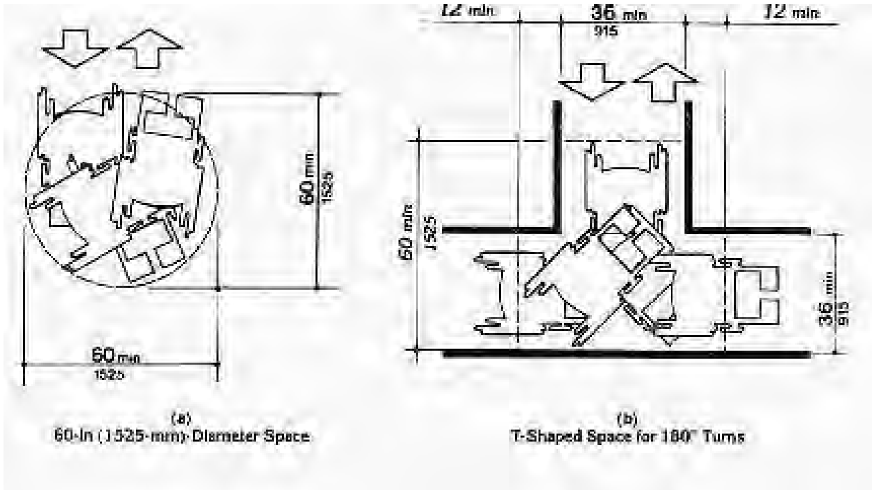
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

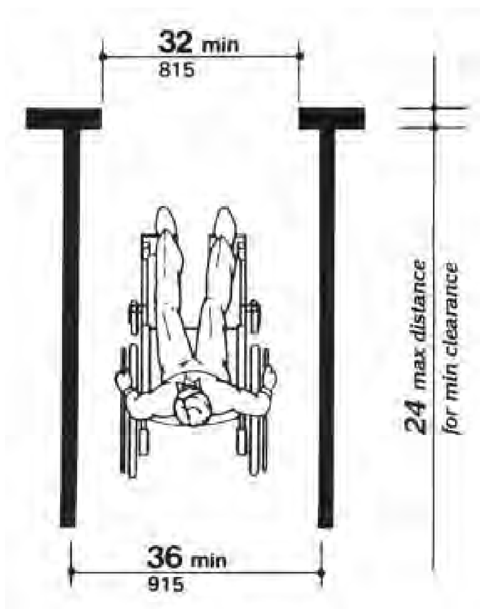


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as “existing”; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60” turning radius in which to make this turn. (the “T” shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an “alteration to the path of travel”, requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32” point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

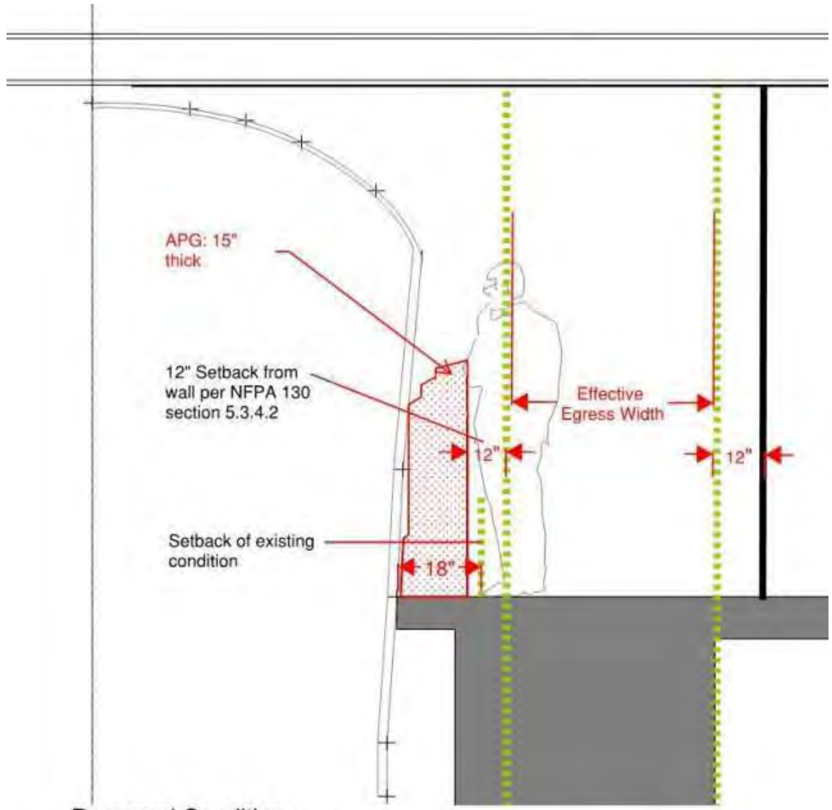
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

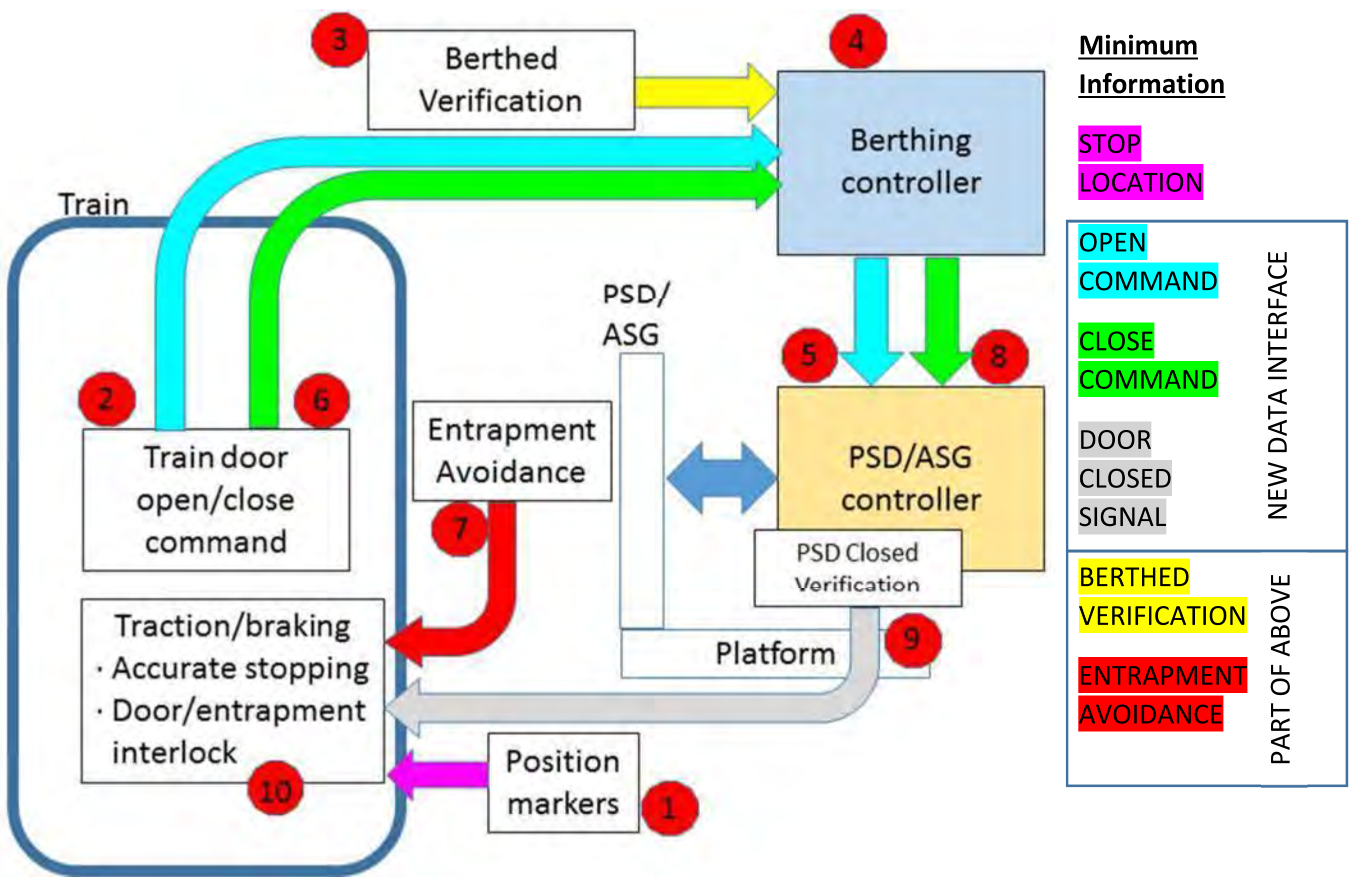
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

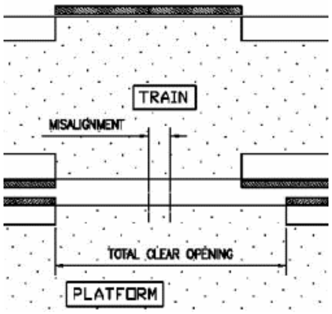
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

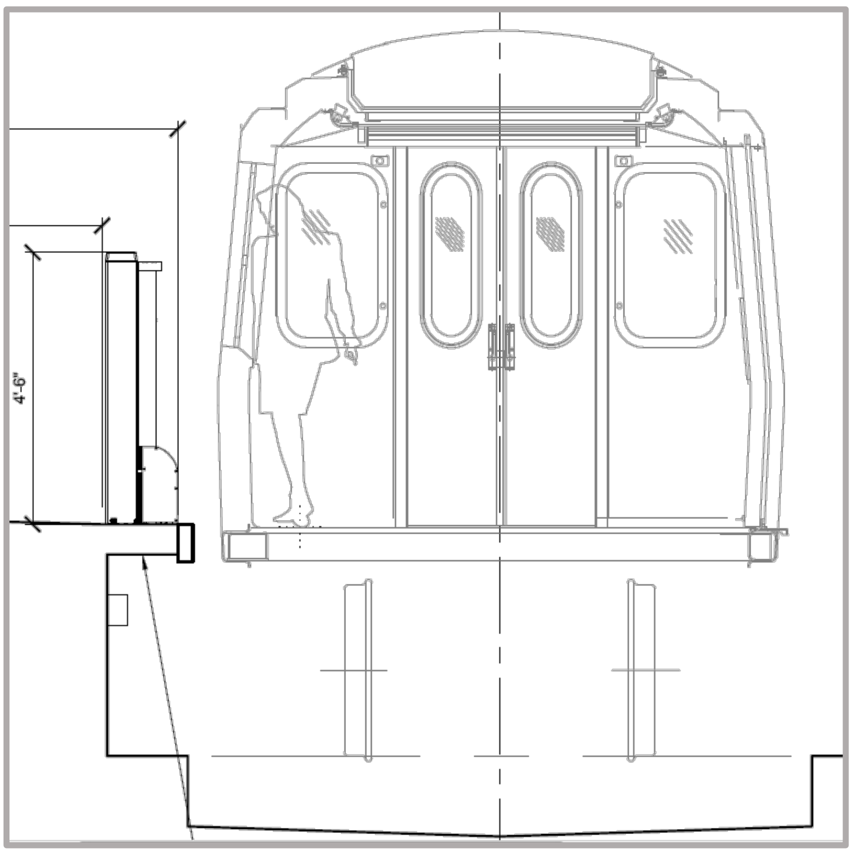


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

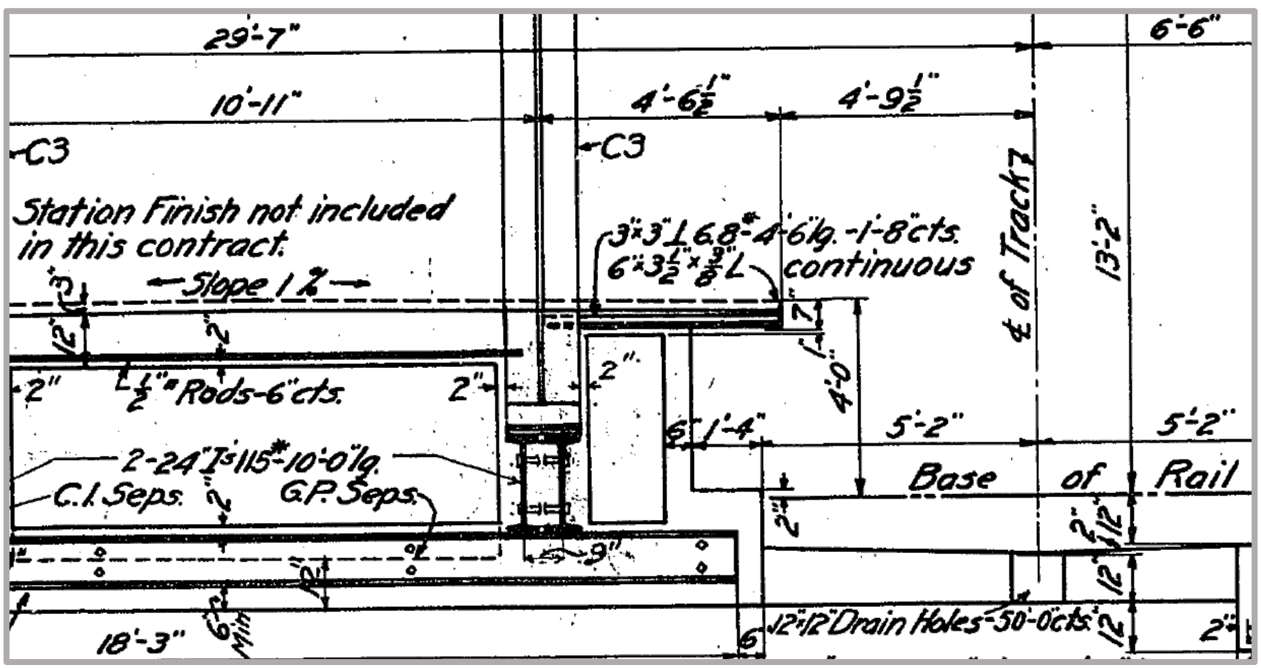

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

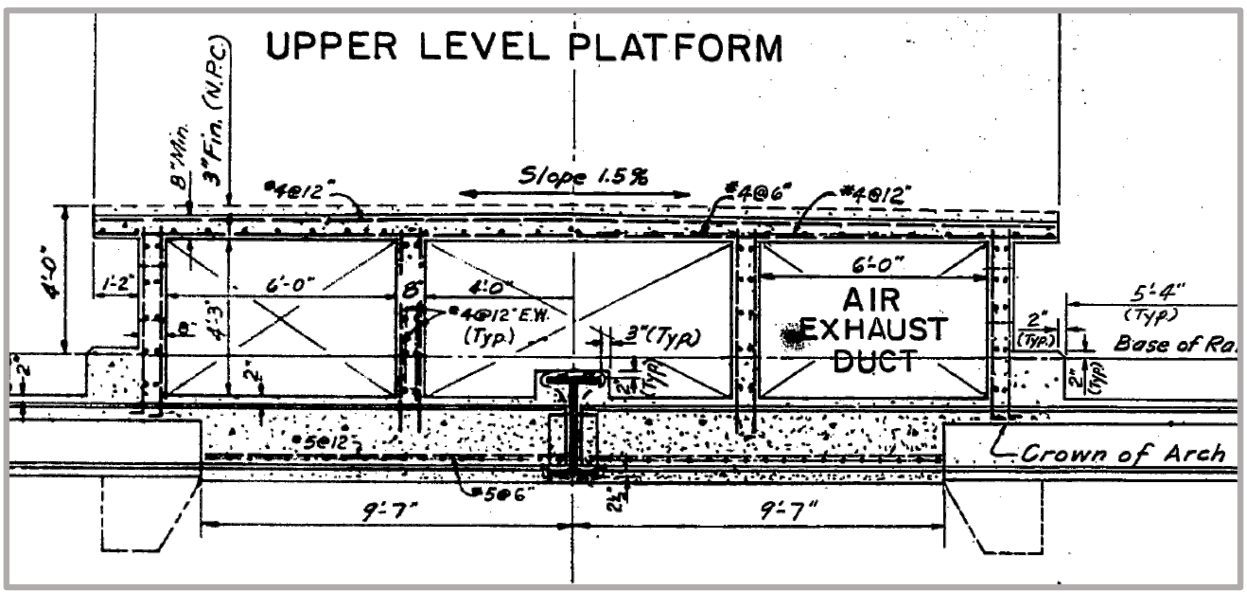

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

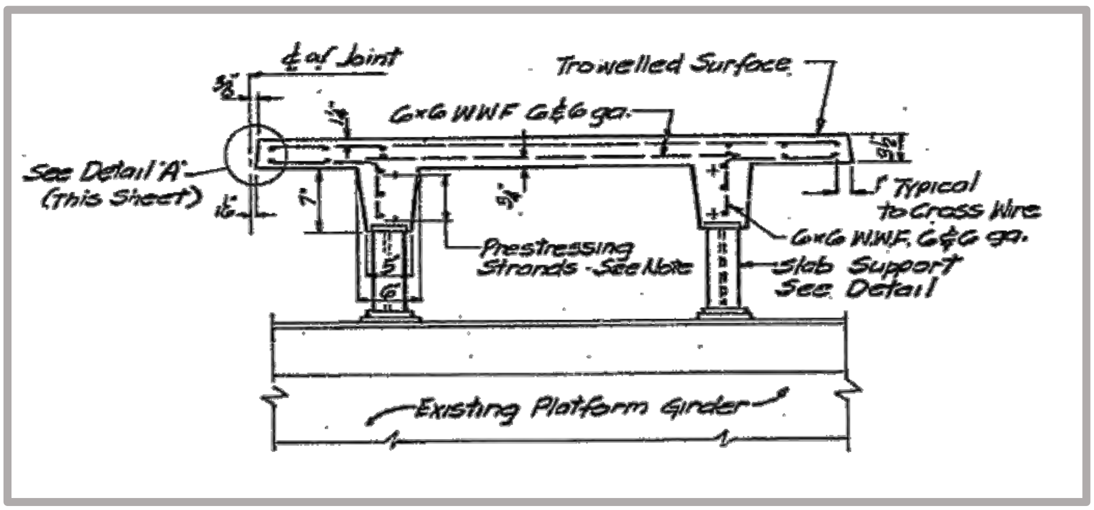

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

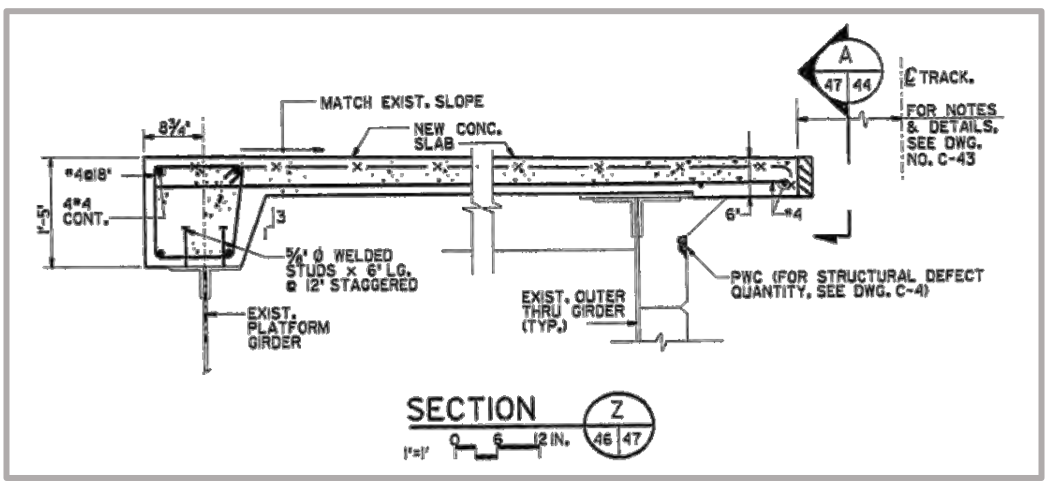

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

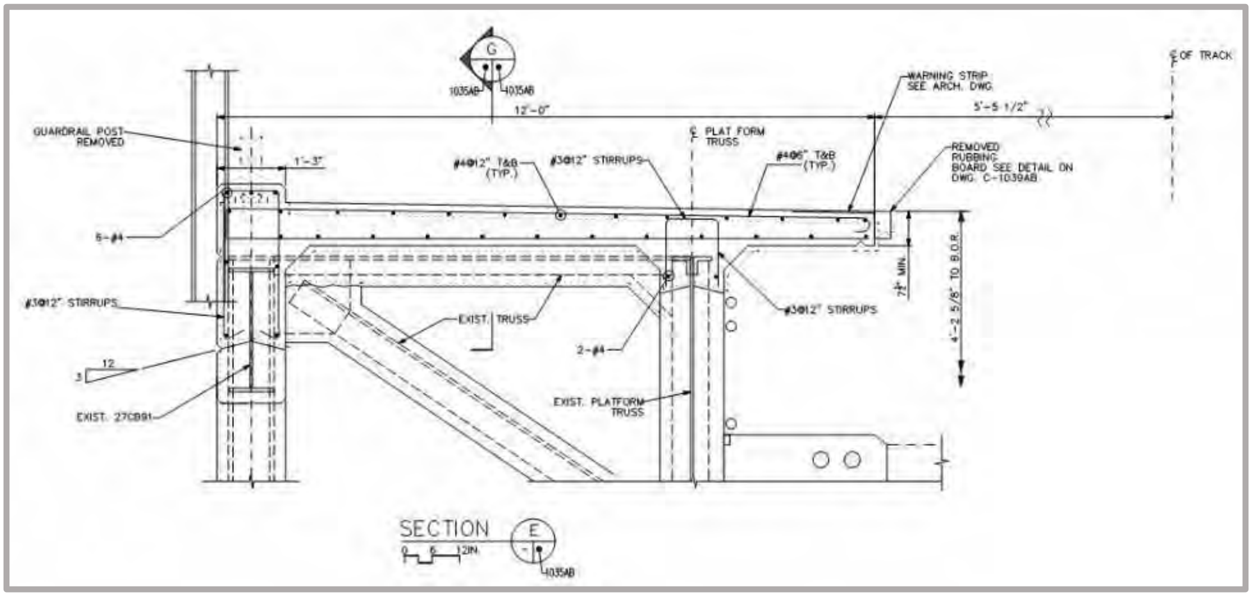

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

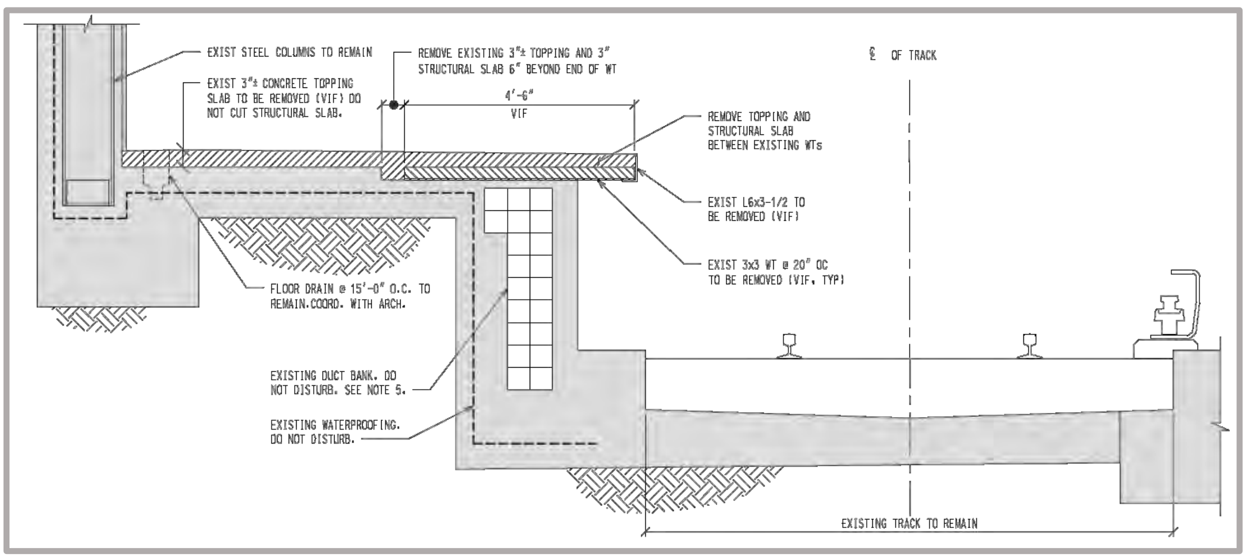

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

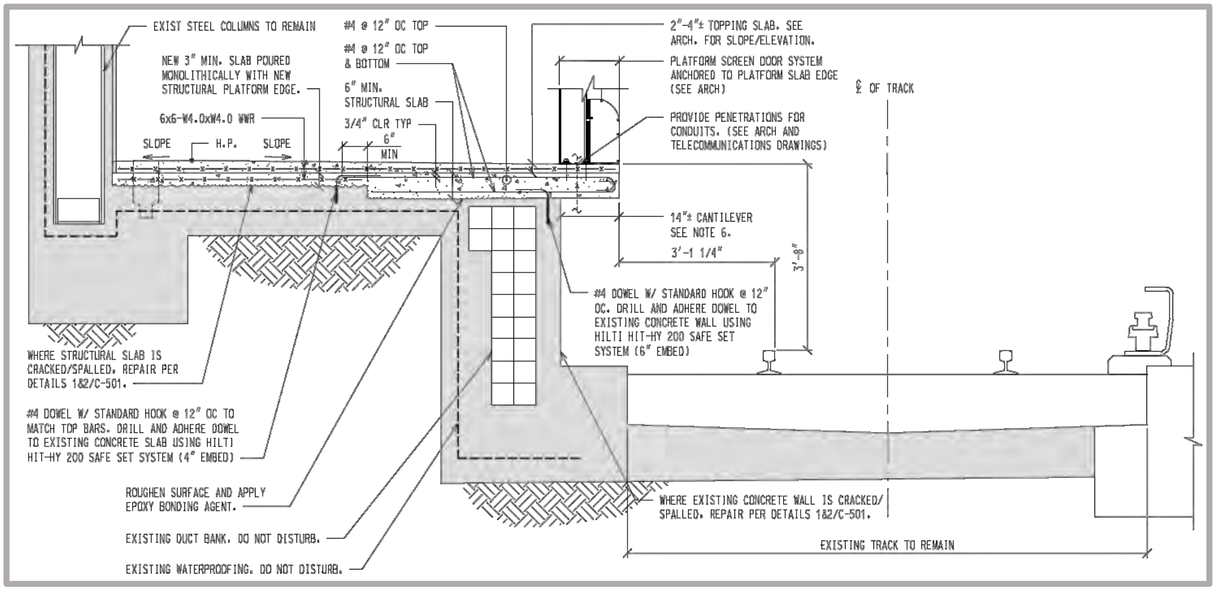

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

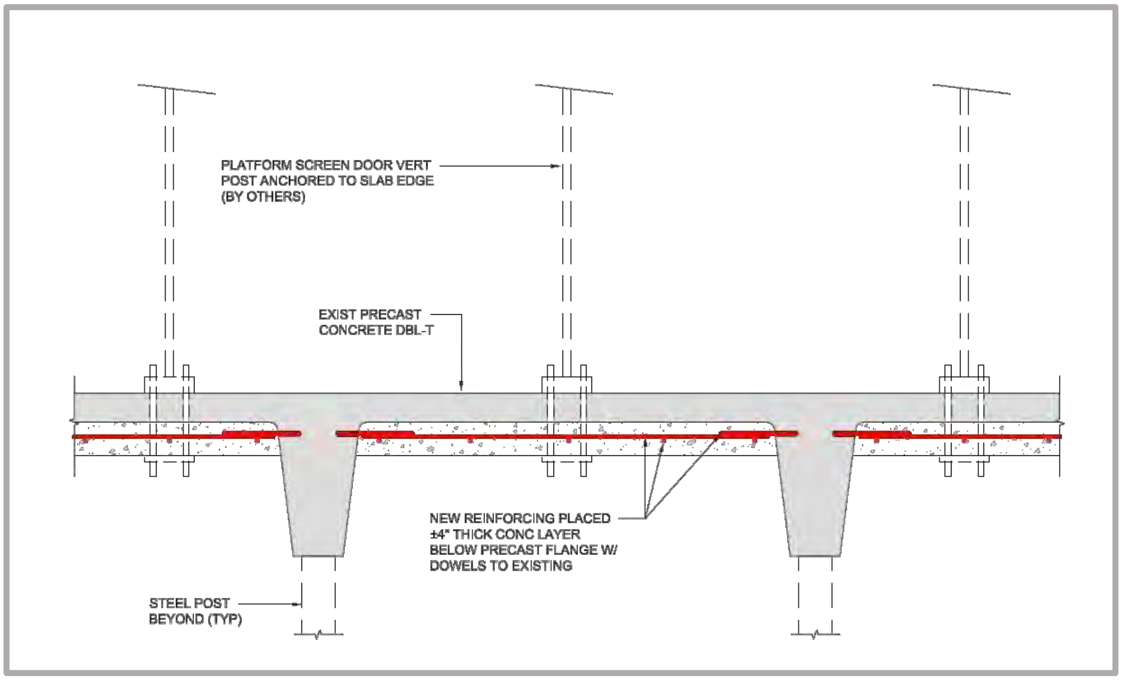

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5’ – 11” of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

MTA/NYCT

January 23, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

3.0 ***Exclusions - Costs not included in the estimate:***

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

MTA/NYCT

January 23, 2019

BASIS OF ESTIMATE

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : DYCKMAN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	550	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	522	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,072**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,072	LF	7	7,504
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,360	SF	12	64,320
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	108	CY	2,500	270,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,074	EA	25	26,850
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,074	EA	25	26,850
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,072	LF	95	101,840
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,072	LF	15	16,080
26	Remove existing platform tiles	1,072	LF	12	12,864
27	Sawcut existing topping concrete at perimeter of removal area	1,072	LF	5	5,360
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,432	SF	8	51,456
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 11'-6" wide strip	656	SF	8	5,248
30	New Work				
31	New concrete topping to match existing	1,072	SF	15	16,080

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : DYCKMAN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	656	SF	15	9,840
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	360	LF	110	39,600
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 3 Doors = 30 No. per platform)	60	EA	15,000	900,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #29 per Platform	58	EA	10,500	609,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,349	SF	750	1,761,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	201,765	201,765
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	60	EA	2,500	150,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : DYCKMAN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,072	LF	60	64,320
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	250	LF	60	15,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	300	LF	60	18,000
76	No allowance for new lighting as if APG's are used, it is not expected to be an issue.		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	180	EA	4,629	833,263
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	180	EA	5,566	1,001,802
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : HOUSTON STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	526	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	526	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,052**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,052	LF	7	7,364
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,260	SF	12	63,120
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	106	CY	2,500	265,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,054	EA	25	26,350
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,054	EA	25	26,350
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,052	LF	95	99,940
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,052	LF	15	15,780
26	Remove existing platform tiles	1,052	LF	12	12,624
27	Sawcut existing topping concrete at perimeter of removal area	1,052	LF	5	5,260
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,312	SF	8	50,496
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,052	SF	15	15,780

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : CANAL STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,101	LF	60	66,060
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Rooms from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	180	EA	4,629	833,263
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	180	EA	5,566	1,001,802
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-1 Line Stations

23-Jan-19

STATION : FRANKLIN STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	525	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	525	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,050**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,050	LF	7	7,350
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,250	SF	12	63,000
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	106	CY	2,500	265,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,052	EA	25	26,300
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,052	EA	25	26,300
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,050	LF	95	99,750
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,050	LF	15	15,750
26	Remove existing platform tiles	1,050	LF	12	12,600
27	Sawcut existing topping concrete at perimeter of removal area	1,050	LF	5	5,250
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,300	SF	8	50,400
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,050	SF	15	15,750

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘2’ SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: March 11, 2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 61 newly evaluated stations, 56 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
    - Limit the ability of a wheelchair to turn within a 5'-0" circle
    - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
    - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the 2-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 8% of the '2' Line stations. Total implementation cost would be \$135.6M for APGs and \$169.9M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of \$931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be \$4.6M.

Summary Table

(8% Feasible 5/ 61)

1.0 Station Assessments

1.01 – MR 310 | 96th Street Station

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 96th Street Station is a below-grade station with two straight center/ island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 13'-6' to 17'-8". The corridor width at this station's elevators is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
96th Street Station

1.02 – MR 311 | 86th Street Station

Summary: *86th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

86th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
86th Street Station

Table of Contents

1.03 – MR 312 | 79th Street Station

Summary: *79th Street Station is not feasible for both APGs and PSDs as the columns which are located 15" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

79th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 15" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1 –** Column 15" from the edge*
79th Street Station

1.04 – MR 313 | 72nd Street Station

Summary: *72nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at five platform stairs as the remaining width would be 15" (see figure 1).*

Description

The 72nd Street Station is a below-grade station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 15'-6". The corridor width at this platform stairs is 30". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
72nd Street Station

1.05 – MR 314 | 66th Street / Lincoln Center Station

Summary: *66th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

66th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
66th Street Station

1.06 – MR 315 | 59th Street / Columbus Circle Station

Summary: *59th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

59th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

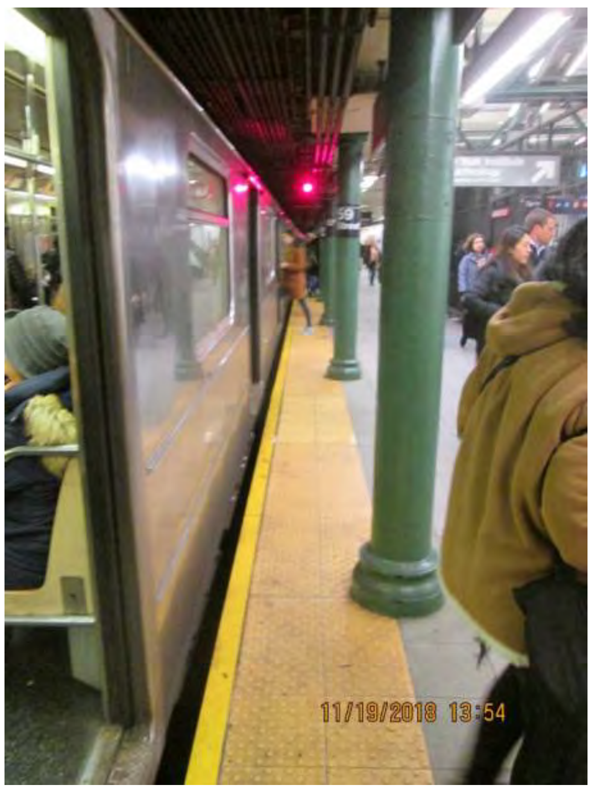

***Figure 1 –** Column 18" from the edge*
59th Street Station

1.07 – MR 316 | 50th Street Station

Summary: *50th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

50th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
50th Street Station

1.08 – MR 317 | 42nd Street / Times Square Station

Summary: *42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the south end of the platform as the remaining width would be 27" (see figure 1).*

Description

The 42nd Street Station is a below-grade station consisting two center / island platforms. The platforms are approximately 21'-2" wide throughout. At the southern end of the northbound platform there are 42" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
42nd Street Station

1.09 – MR 318 | 34th Street Penn Station

Summary: *34th Street Penn Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 5'-0" (see figure 1).*

Description

34th Street Station is a below-grade station consisting of both side and center / island platform. The express 2 and 3 trains utilize the center / island platform. The platform is approximately 24'-8"' wide throughout, narrowing to 5'-0" at the south end of the southbound platform and 5'-3" at the northbound platform. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress via emergency exit doors with an installed PSD system. See figure 1 for reference.

Figure 1 *– Non-Compliant egress condition*
34th Street Station

1.10 – MR 319 | 28th Street Station

Summary: *28th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at south end of the southbound platform as the remaining width would be 33" (see figure 1).*

Description

The 28th Street Station is a below-grade station with two platforms. The platform structures are cast-in-place concrete. The width of the platforms are approximately 11'-10". The implementation of a platform edge barrier would reduce this width at the south end of the southbound platform below the required minimum of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

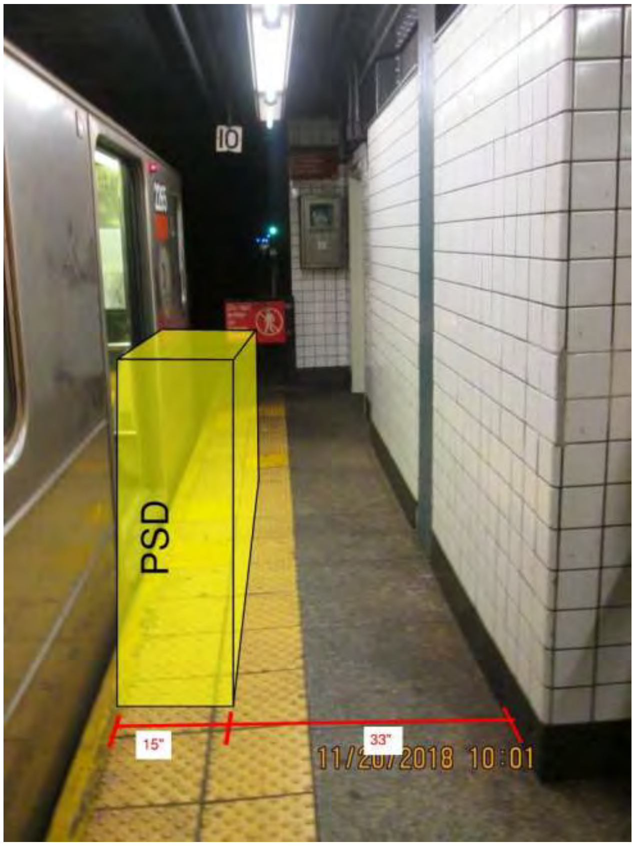

Figure 1 *– Non-Compliant ADA condition*
28th Street Station

1.11 – MR 320 | 23rd Street Station

Summary: *23rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-10" (see figure 1).*

Description

23rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-10' to 11'-10".

Platform width at the ends of the northbound & southbound platform are 5'-10" or 70". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

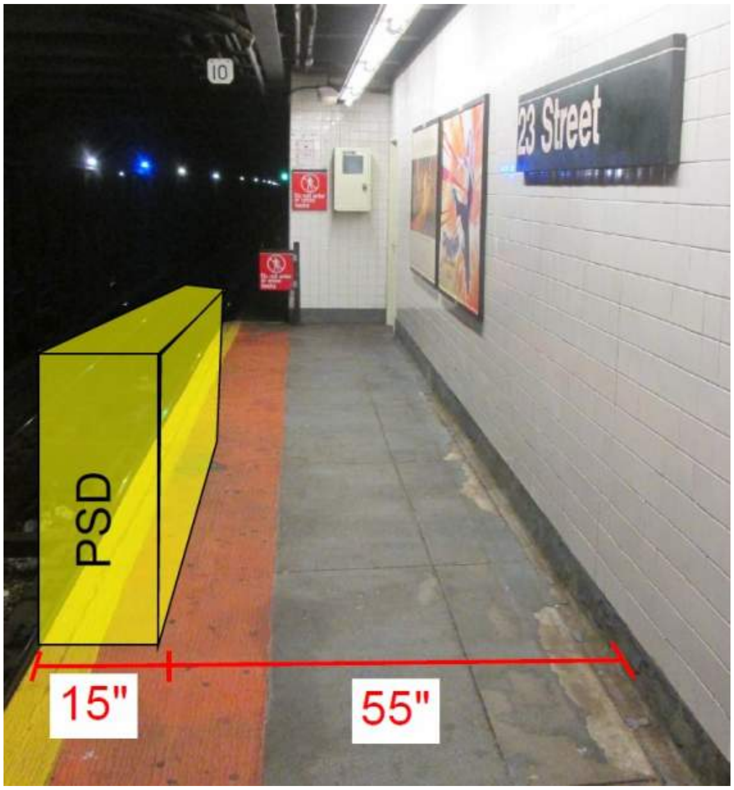

***Figure 1** – Non-Compliant egress condition*
23rd Street Station

1.12 – MR 321 | 18th Street Station

Summary: *18th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 5'-0"" (see figure 1).*

Description

18th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 11'-6".

Platform width at the southern end of the southbound platform is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
18th Street Station

1.13 – MR 322 | 14th Street Station

Summary: *14th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-0"" (see figure 1).*

Description

14th Street Station is a below-grade station with two straight center/ island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 19'-4".

Platform width at the southern end of both platforms is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
14th Street Station

1.14 – MR 323 | Christopher Street Station

Summary: *Christopher Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Christopher Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 10'-4" to 11'-8". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar.

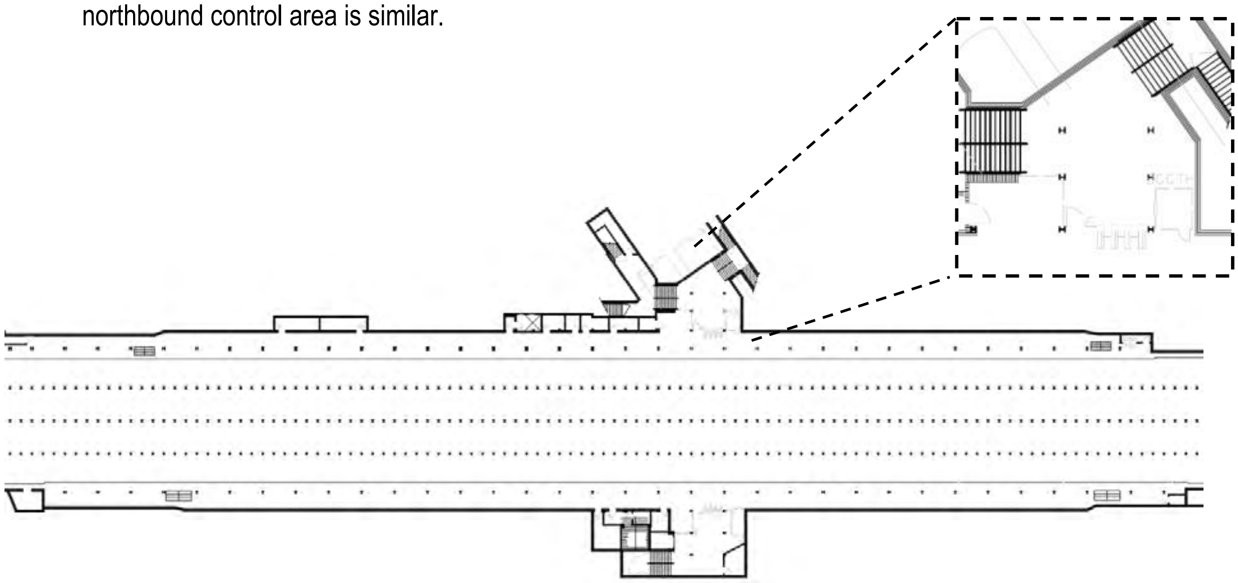

Figure 1 *– Congested/Narrow Station Plan*
Christopher Street Station

(A Division train shown; B Division requires same dimension

1.15 – MR 324 | Houston Street Station

Summary: *Houston Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Houston Street Station is a below ground station with two side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 12-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area of the station (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for '2' Line Stations
(Houston Street Station)

Houston Street Station

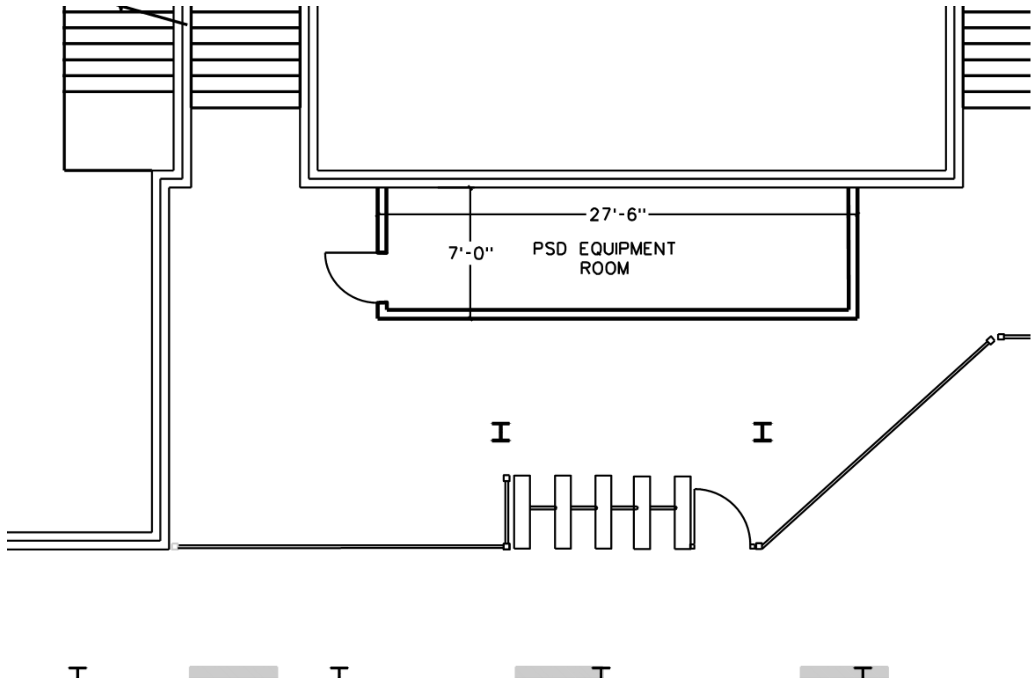

Figure 2 *– PSD Equipment Room 1 Detail*
Houston Street Station

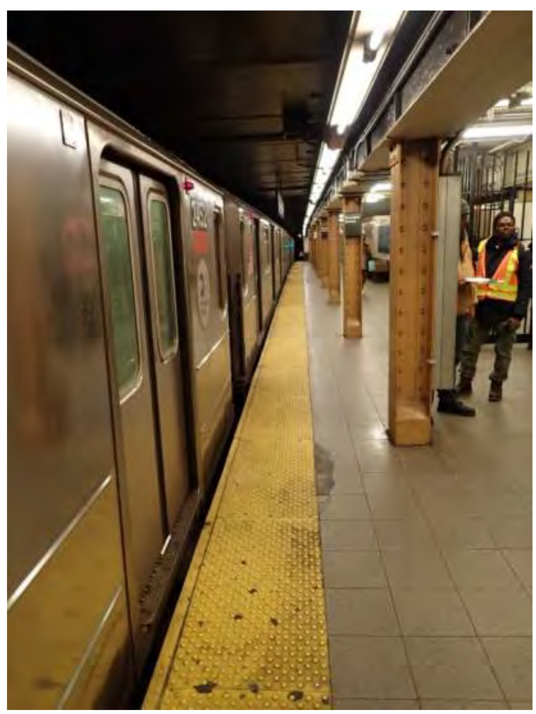

Figure 3 *– Typical platform view*
Houston Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Houston Street Varick St.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	40.8
Apparent Power (kVA)	51.0
Station Peak Demand Load, Max Current, (A)	141.7
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	299
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	501
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on observations of breaker schedule. Only partial one line diagram (for tunnel lighting) is available.

Table 1. Normal Service Power Capacity Analysis

Station
Power Capacity Analysis (reserve service)

Station Name	Houston Street Varick St.
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	10.4
Apparent Power (kVA)	13.0
Station Peak Demand Load, Max Current, (A)	36.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	194
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	606
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on observations of breaker schedule. Only partial one line diagram (for tunnel lighting) is available.

***Table 2**. Reserve Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be \$27.2M to install APGs and \$34.2M to install PSDs (See Appendix E)

1.16 – MR 325 | Canal Street Station

Summary: *Canal Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Canal Street Station is a below ground station with two side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 12-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the abandoned passageway at the south end of the station (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system.

Canal Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge on the inside face of the columns. No lighting re-configuration will be required as a result of a PSD installation.

Power:

The Normal EDR was not accessible at the time of survey. However, the electrical reserve service has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (reserve service)

Station Name	Canal Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	37.2
Apparent Power (kVA)	46.5
Station Peak Demand Load, Max Current, (A)	130.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	288
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	312
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on observations of breaker schedule. Only partial one line diagram (for tunnel lighting) is available. Also the above capacity is based on demand KW for Reserve power.

***Table 1**. Reserve Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $35.3M to install PSDs (See Appendix E)

1.17 – MR 326 | Franklin Street Station

Summary: *Franklin Street is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Franklin Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. Column faces measure approximately 4'-0" from the platform edge. The platform widths are approximately 11-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the early 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.1M to install APGs and $33.7M to install PSDs (See Appendix E)

Table of Contents

1.18 – MR 327 | Chambers Street Station

Summary: *Chambers Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Chambers Street Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 17'-2". The corridor width at the southern end of the southbound platform is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Chambers Street Station

1.19 – MR 331 | Park Place Station

Summary: *Park Place Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the escalator as the remaining width would be 23" (see figure 1).*

Description

The Park Place Station is a below-grade station with one straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 17'-10". At the columns on either side of the escalator, there is 38" clearance. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Park Place Station

1.20 – MR 332 | Fulton St. Station

Summary: *Fulton St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Fulton Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 13'-6" throughout. At the south end of the southbound platform, the existing clearance is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
Fulton Street Station

1.21 – MR 333 | Wall Street Station

Summary: *Wall Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 17" (see figure 1).*

Description

The Wall Street Station is a below-grade station with one center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 14'-0", narrowing to 6'-6" at the end. At several of the stairs, the existing clearance is 32". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 17" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

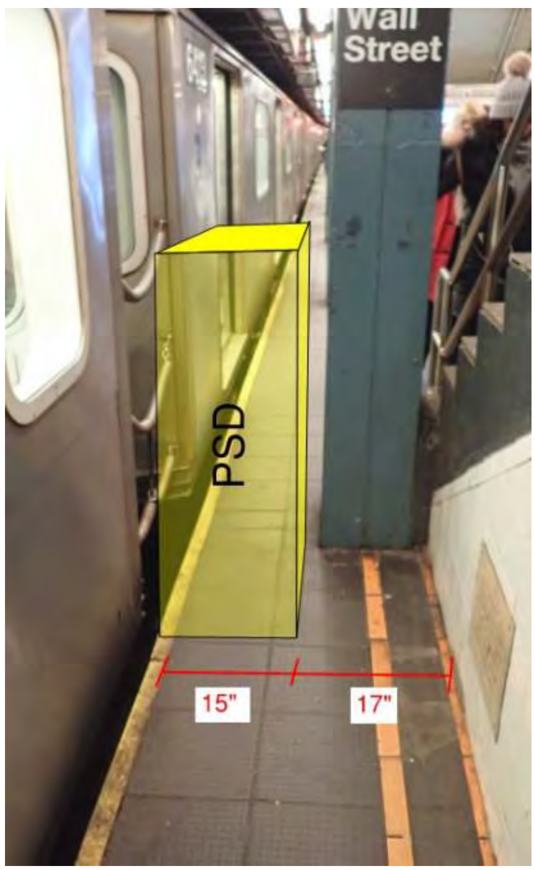

Figure 1 *– Non-compliant ADA condition*
Wall Street Station

1.22 – MR 334 | Clark Street Station

Summary: *Clark Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 9" (see figure 1)..*

Description

Clark Street Station is a below-grade station with one center / Island platform. The platform structure is cast in place concrete. The width of the platform is approximately 15'-6. At the two stairs, columns flanking the stairs leave 24" of clearance. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 9" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Clark Street Station

1.23 – MR 335 | Borough Hall Station

Summary: *Borough Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

Borough Hall Station is a below-grade station with two straight side platforms. The platform structures are cast in place concrete. The width of the platforms varies from 3'-2" to 11'- 8". At the south end of the southbound platform the corridor width to the platform wall is only 3'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

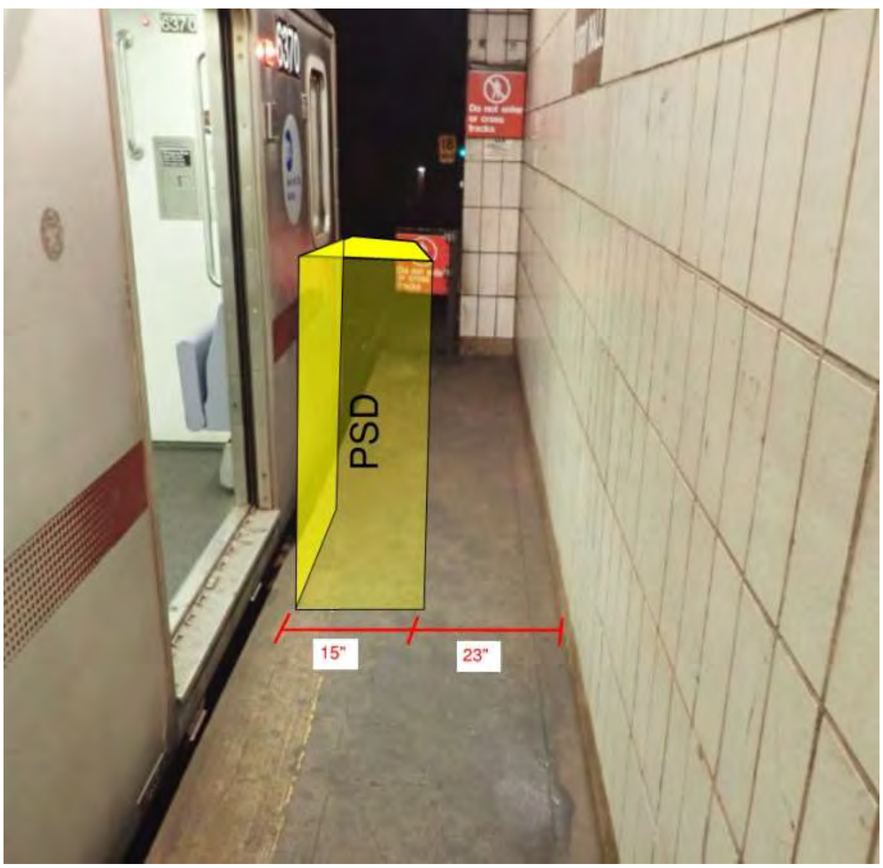

***Figure 1** – Non-compliant ADA condition*
Borough Hall Station

1.24 – MR 336 | Hoyt Street Station

Summary: *Hoyt Street Station is not feasible for both APGs and PSDs. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the north end of the northbound as the remaining width would be 19" (see figure 1).*

Description

Hoyt Street Station is a below-grade station with two straight side platforms. The platform structures are cast in place concrete. The width of the platforms varies from 11'-0" to 13'- 0, and narrowing at the ends. At the north end of the northbound platform, the existing clearance at the columns is 34". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 19" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

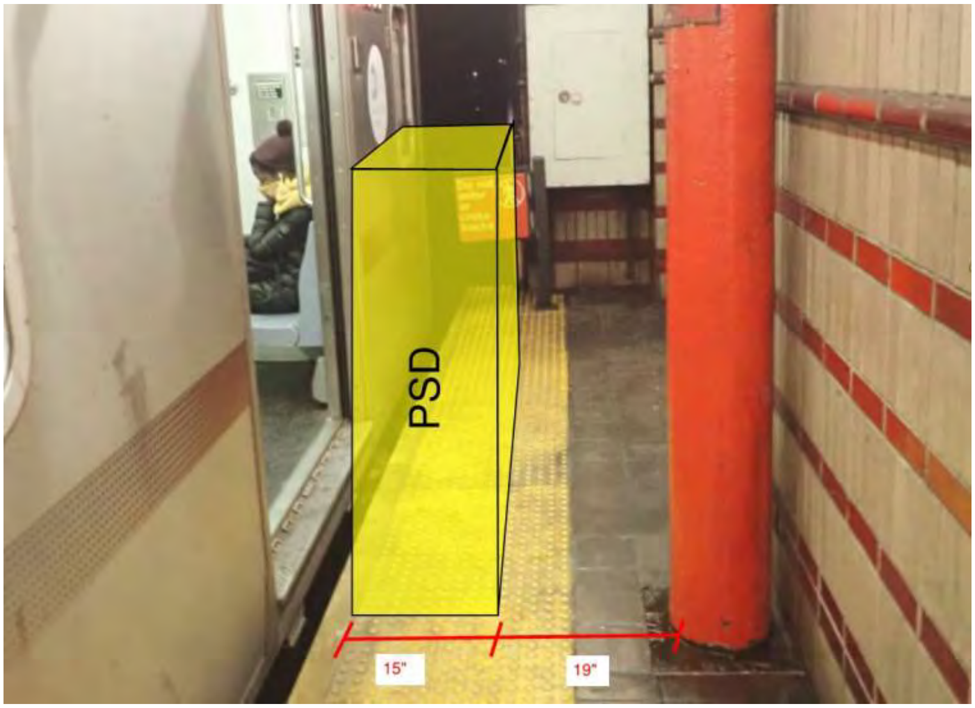

Figure 1 *– Non-compliant ADA condition*
Hoyt Street Station

1.25 – MR 337 | Nevins Street Station

Summary: *Nevins Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description

Nevins Street Station is a below-grade station with two center / island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios

Figure 1 *– Non-compliant ADA condition*
Nevins Street Station

.

1.26 – MR 338 | Atlantic Avenue Barclay Ctr Station

Summary: *Atlantic Avenue Barclay Ctr. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

The Atlantic Avenue Barclay Ctr. Station is a below-grade station with two straight side platforms and a center / island platform. The 2 trains stop at the side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 6'-8' to 18'-0". The corridor width at the staircase at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The non-compliant condition noted above could be remedied by moving the stopping location of the train. The proposal to move the stopping position of trains in specific stations would need to be studied by NYCT Signals Engineering to determine the impact to signals and signals equipment between that station and a series of adjacent stations all the way to the nearest interlocking. In many cases signals equipment at several locations would need to be relocated and rewired. The only way to fully determine this is to make an analysis of the existing signals system in that area.

Since that type of task is outside the scope of the PSD Feasibility Study, it is concluded that the current train stopping position is fixed. Given this condition, the ADA and/or Code analysis is being used for the feasibility analysis.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Atlantic Ave Station

1.27 – MR 339 | Bergen Street Station

Summary: *Bergen Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bergen Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located only at the center of the platforms along the platform edge. Column faces measure approximately 3'-8" from the platform edge. The platform widths are approximately 7-10" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

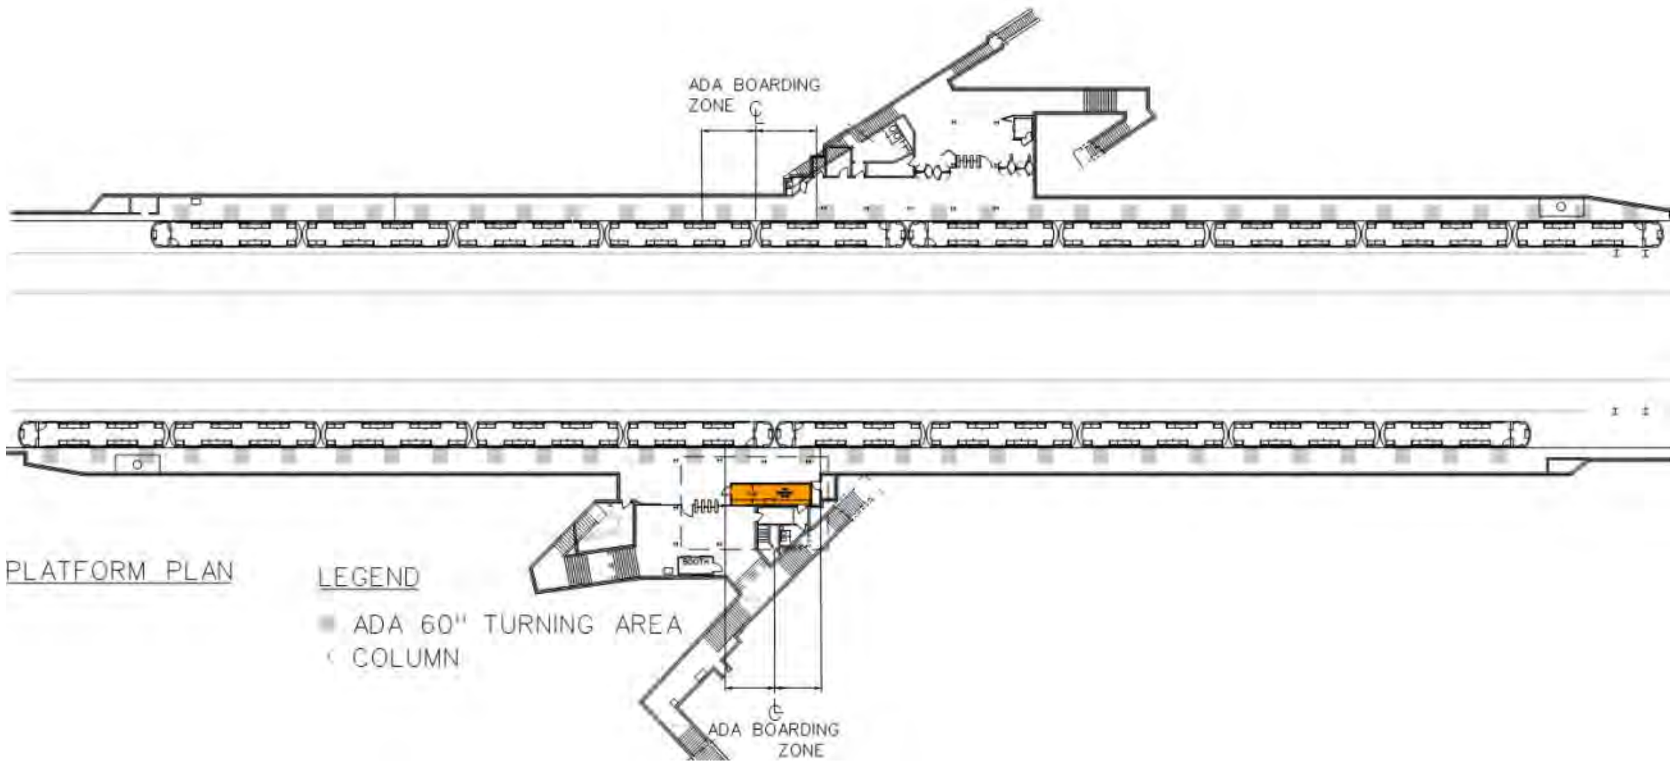

Figure 1 – *Overall Station Plan*
Bergen Street Station

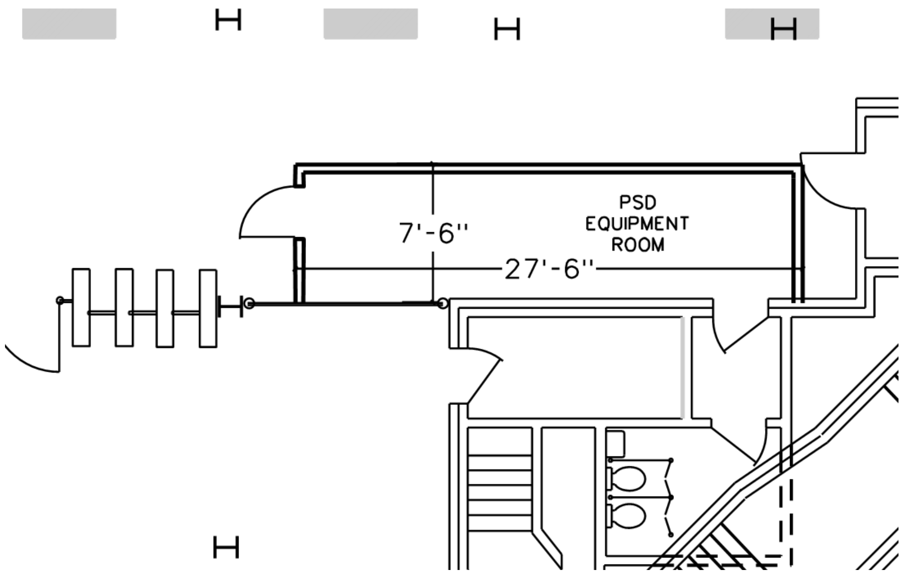

Figure 2 *– PSD Equipment Room 1 Detail*
Bergen Street Station

Figure 3 *– Typical platform view*
Bergen Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

The Reserve EDR was not accessible at the time of survey. However, the Normal electrical service has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Bergen Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	40.8
Apparent Power (kVA)	51.0
Station Peak Demand Load, Max Current, (A)	141.7
Maximum Amount of Doors	40.0
PSD Total Load Including All Miscellaneous Loads, (A)	121.6
Total Load (Station Peak + PSD), (A)	263
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	537
Is Electrical Service Adequate?	**Yes**
Notes	Service capacity data is based on observations of breaker schedule.

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $28.9M to install APGs and $33.3M to install PSDs (See Appendix E)

Table of Contents

1.28 – MR 340 | Grand Army Street Station

Summary: *Grand Army Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Grand Army Street Station is a below-grade station with one straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 32'-4" throughout. The corridor width at this station's western end is 44". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Grand Army Plaza Station

1.29 – MR 341 | Eastern Parkway Brooklyn Street Station

Summary: *Eastern Parkway Brooklyn Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-6" (see figure 1).*

Description

Eastern Parkway Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-6' to 11'-10".

Platform width at the ends of the platforms is 5'-6" or 66". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

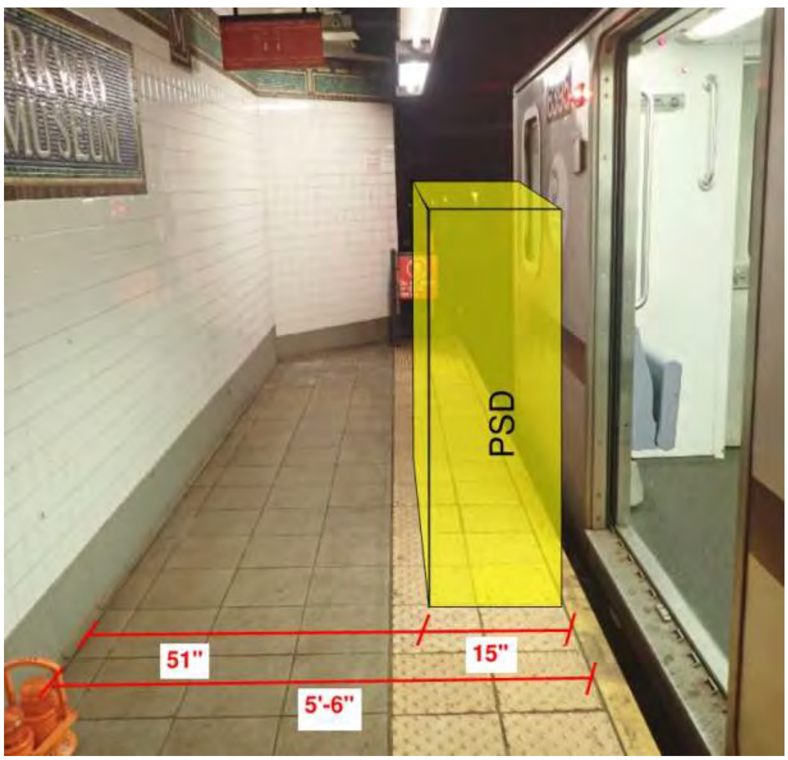

***Figure 1** – Non-Compliant egress condition*
Eastern Parkway Station

1.30 – MR 342 | Franklin Avenue Botanic Garden Station

Summary: *Franklin Avenue Botanic Garden Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Franklin Avenue Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Franklin Avenue Station

1.31 – MR 353 | President Street Station

Summary: *President Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at five platform stairs as the remaining width would be 27" (see figure 1).*

Description

President Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 20'-0" throughout. The corridor width at southern end of this platform is 42". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 27" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
President Street Station

1.32 – MR 354 | Sterling Street Station

Summary: *Sterling Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Sterling Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. The platform widths are approximately 11-10” throughout. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27’-6” x 7’-0”.

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would be required for the installation of both an APG and PSD system.

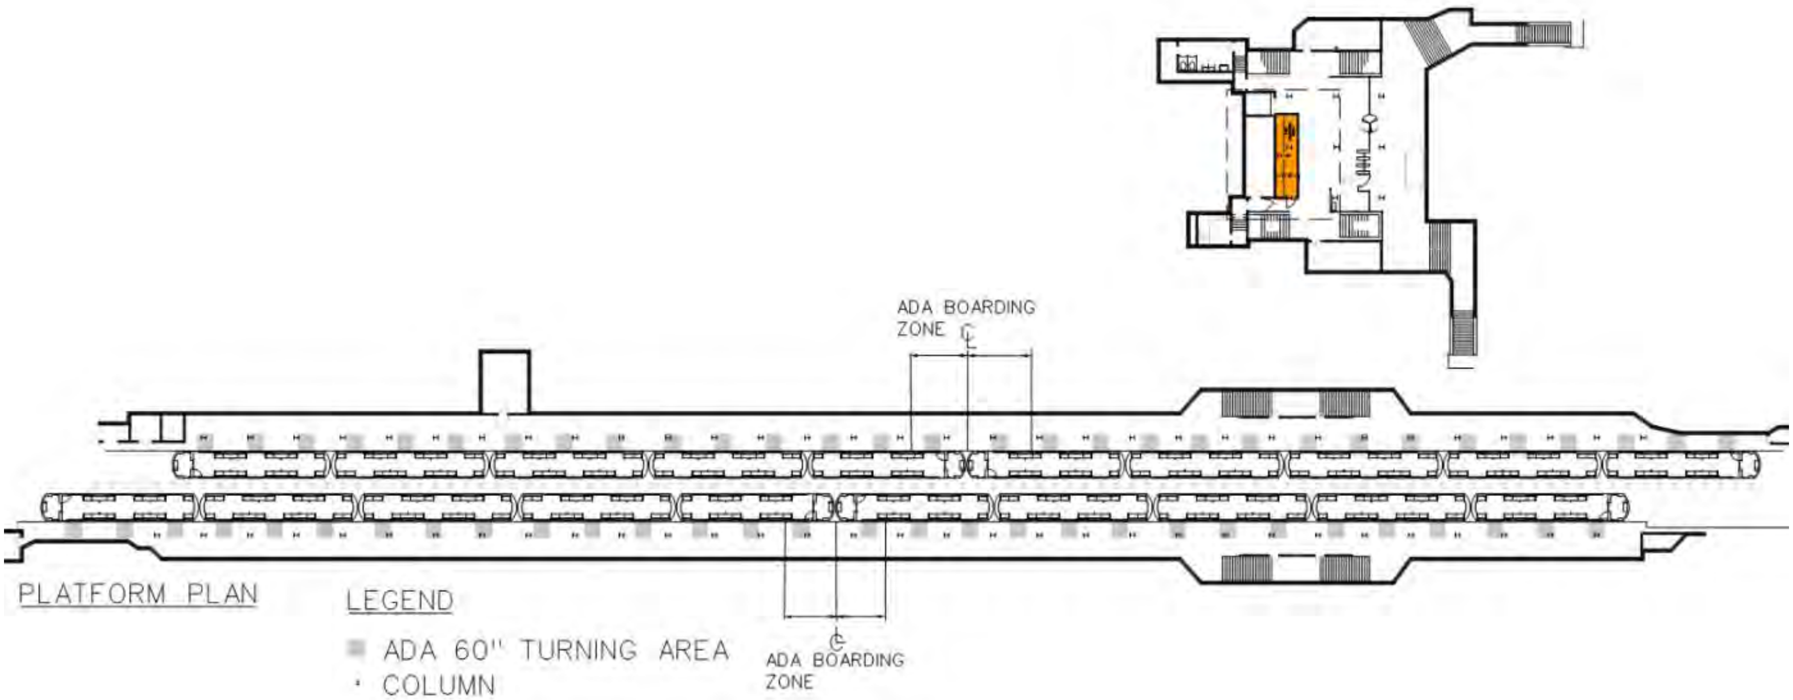

Figure 1 – Overall Station Plan
Sterling Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $26.7M to install APGs and $33.4M to install PSDs (See Appendix E)

1.33 – MR 355 | Winthrop Street Station

Summary: *Winthrop Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Winthrop Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-8' to 11'-10". The corridor width at the southbound end of the platforms is 3'-8". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

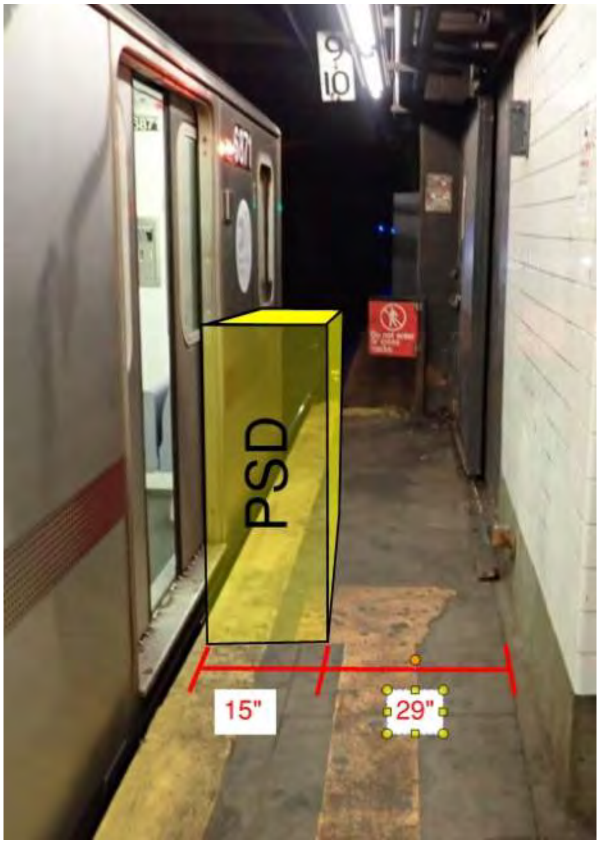

Figure 1 *– Non-compliant ADA condition*
Winthrop Street Station

1.34 – MR 356 | Church Avenue Station

Summary: *Church Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Church Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns along each platform edge. The platform width varies from 7'-10" to 11'-10" throughout. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2 below shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar.

.

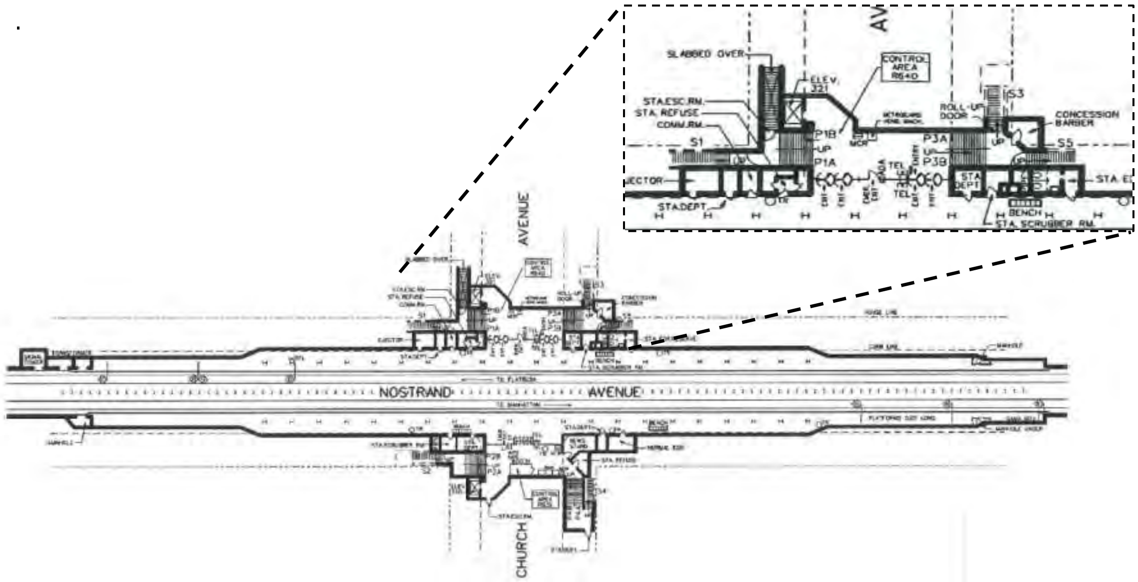

Figure 1 – Congested / Narrow Station Plan
Church Avenue Station

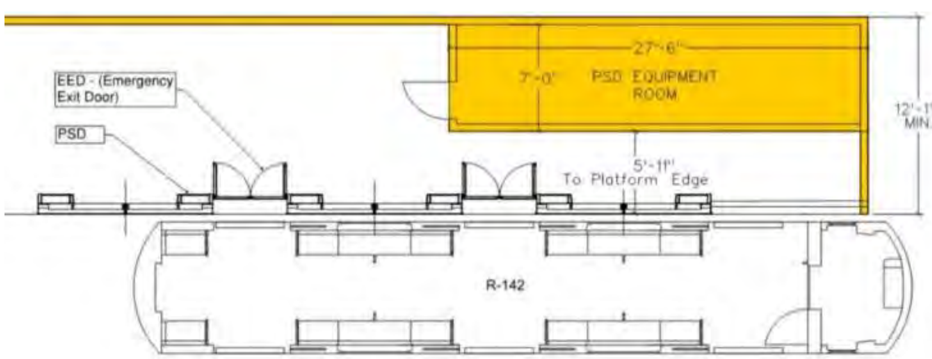

Figure 2 – Diagram demonstrating minimum platform width dimensions
Church Avenue Station

1.35 – MR 357 | Beverly Road Station

Summary: *Beverly Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the northbound platform as the existing width is 5'-9" (see figure 1).*

Description

Beverly Road Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-9' to 11'-10".

Platform width at the north end of the northbound platform is 5'-9" or 69". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

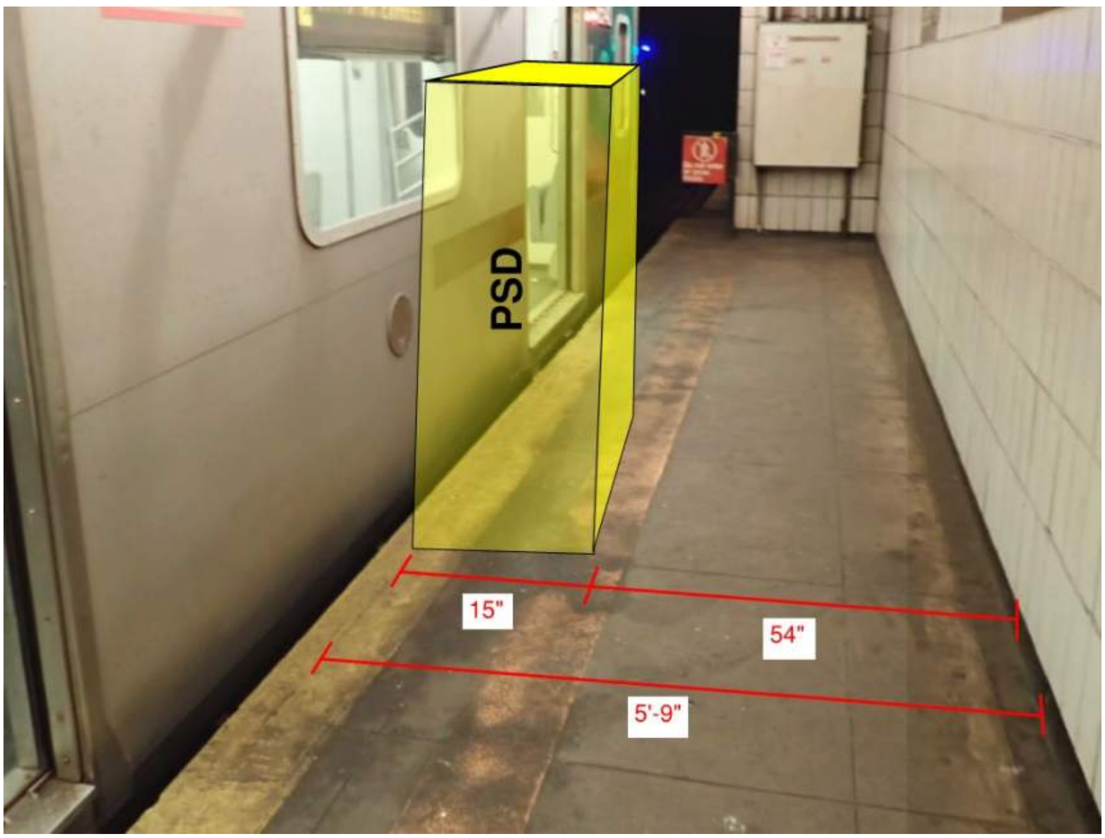

***Figure 1** – Non-Compliant egress condition*
Beverly Road Station

1.36 – MR 358 | Newkirk Avenue Station

Summary: *Newkirk Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the both platforms as the existing width is 5'-9" (see figure 1).*

Description

Newkirk Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-9' to 11'-10".

Platform width at the ends of the northbound & southbound platform are 5'-9" or 69". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

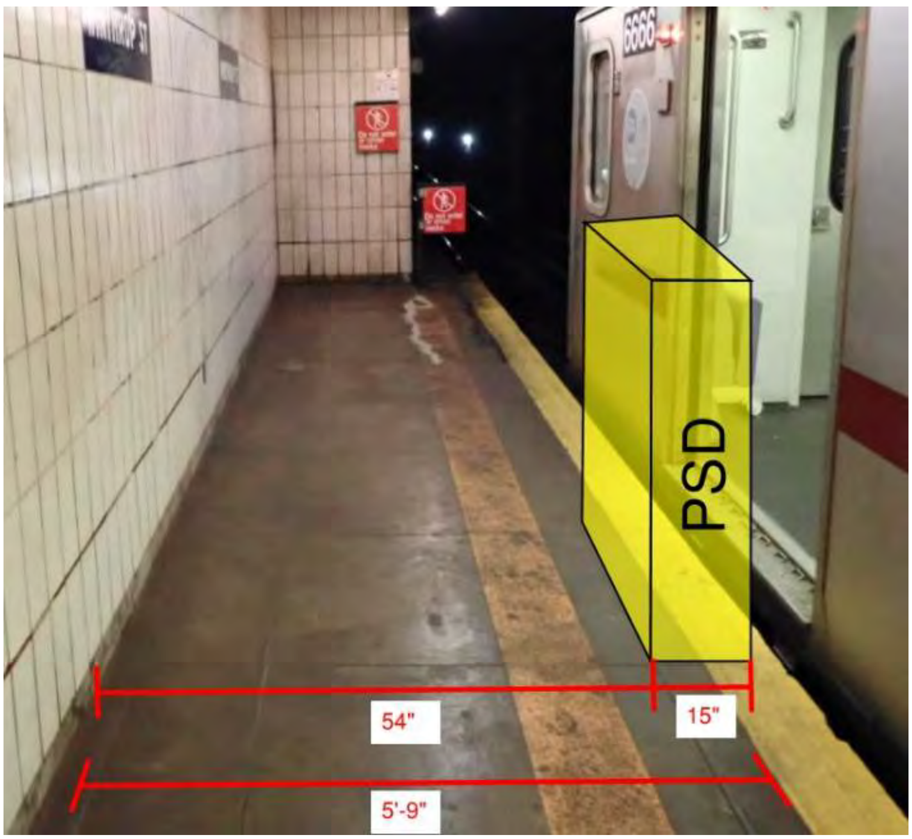

Figure 1 *– Non-Compliant egress condition*
Newkirk Avenue Station

Table of Contents

1.37 – MR 359 | Flatbush Avenue Brooklyn College Station

Summary: *Flatbush Avenue Brooklyn College Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

The Flatbush Avenue Brooklyn College Station is a below-grade terminus station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the northern end of the northbound platform is 2'-4". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 13" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Flatbush Avenue Brooklyn College Station

1.38 – MR 416 | 241st Street Wakefield Station

Summary: *241st Street Wakefield is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The 241st Street Station is an elevated terminus station with two closed side platforms and one open center/island platform. The platform structures are precast concrete. The width of the center platform is approximately 15'-0" throughout. The platform is straight with one row of columns supporting its respective station canopies. This station is also infeasible due to non-compliant ADA dimensions at south end of the platforms, where the existing 30" of width will be reduced to 15" with the installation of PSDs. See figure 1 & 2 for reference.

West Farms Square Station

1.50 – MR 428| 174th Street Station

Summary: *174th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The 174th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 7'-8" to 12'-4". The platforms are mildly curved with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*

174th Street Station

1.51 – MR 429 | Freeman Street Station

Summary: *Freeman Street is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Freeman Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 7'-0" to 13'-8". The platforms are mildly curved with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Freeman Street Station

1.52 – MR 430 | Simpson Street Station

Summary: *Simpson Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Simpson Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 6'-0" to 13'-10". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

1.53 – MR 431 | Intervale Avenue Station

Summary: *Intervale Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Intervale Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 6'-0" to 13'-10". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

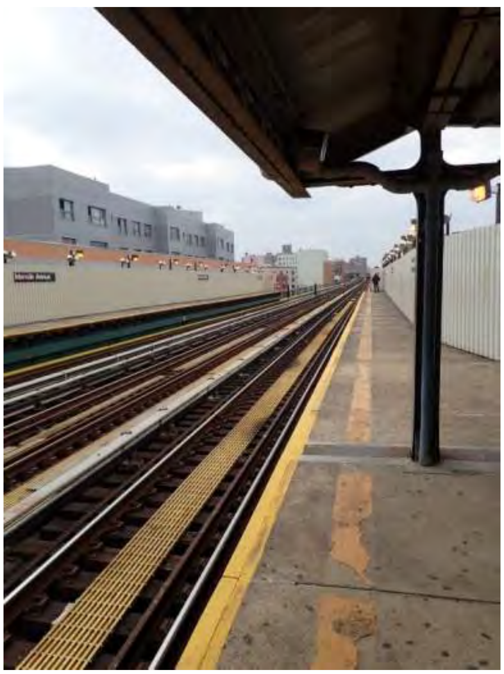

Figure 1 *– General Station Condition*
Intervale Avenue Station

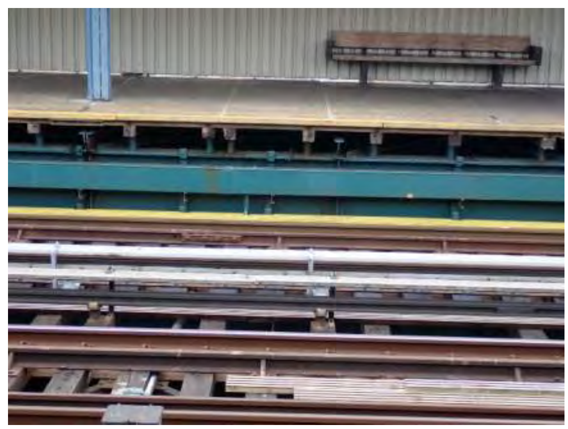

Figure 2 *– Precast Slab*
Intervale Avenue Station

1.54 – MR 432 | Prospect Avenue Station

Summary: *Prospect Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Prospect Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 7'-4" to 14'-4". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Prospect Avenue Station

Figure 2 *– Precast Slab*
Prospect Avenue Station

1.55 – MR 433 | Jackson Avenue Station

Summary: *Jackson Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Jackson Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 6'-6" to 14'-0". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Jackson Avenue Station

Figure 2 *– Precast Slab*
Jackson Avenue Station

1.56 – MR 434 | 3rd Avenue 149th Street Station

Summary: *3rd Avenue 149th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

3rd Avenue 149th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
3rd Avenue 149th Street Station

1.57 – MR 435 | 149th Street Grand Concourse Station

Summary: *149th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 35" (see figure 1).*

Description

The 149th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the western ends of the platforms is 4'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 35" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
149th Street Station

1.58 – MR 438 | 135th Street Station

Summary: *135th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

135th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

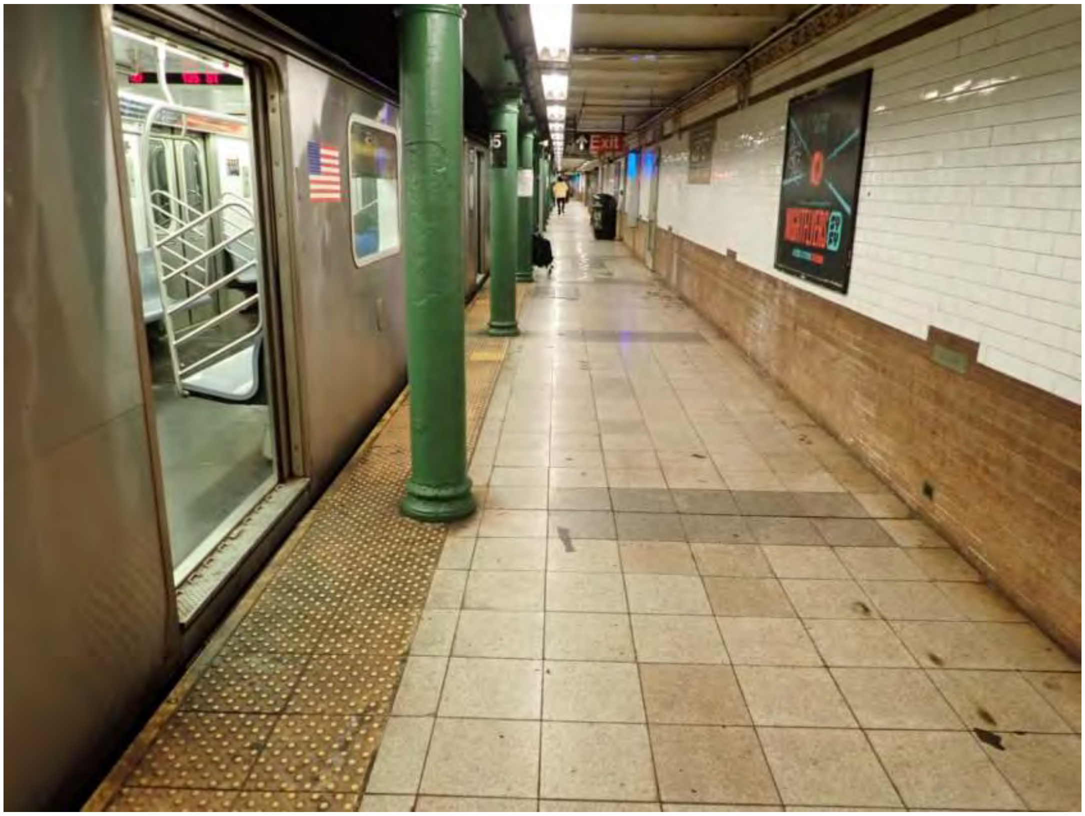

Figure 1 – *Column 16" from the edge*
135th Street Station

1.59 – MR 439 | 125th Street Station

Summary: *125th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

125th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
125th Street Station

1.60 – MR 440 | 116th Street Station

Summary: *116th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

116th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
116th Street Station

1.61 – MR 441 | 110th Street Central Park North Station

Summary: *110th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-0" (see figure 1).*

Description

110th Street Station is a below-grade station with one center/island platform. The platform structure is cast-in-place concrete. The width of the corridors at this station ranges from 5'-0' to 21'-6".

The corridor width at the center of this platform adjacent to the control area is constrained to o 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

Appendices: Table of Contents

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for <u>Tier 2 Stations'</u> screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for <u>Tier 3 Stations</u> will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

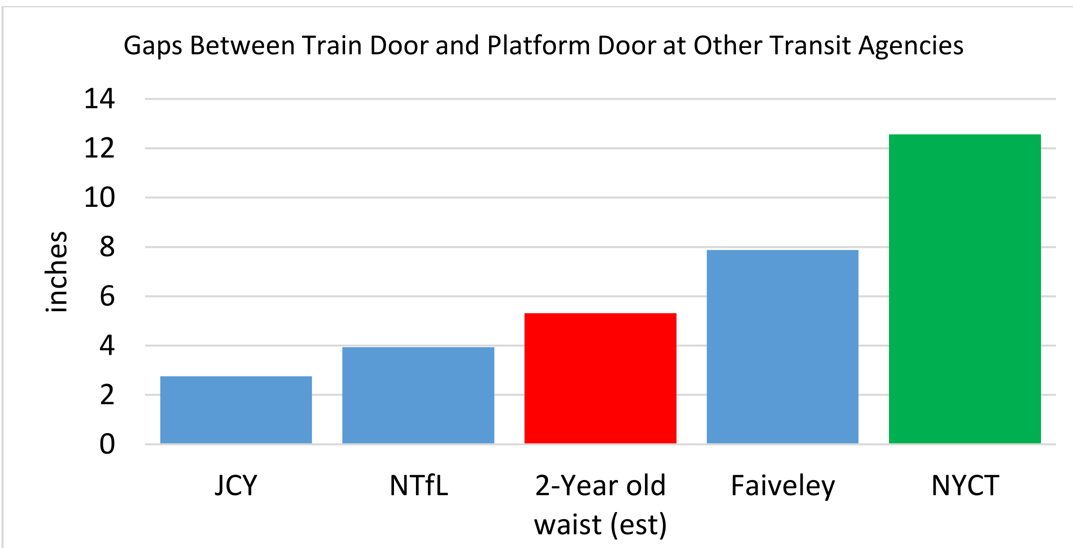

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

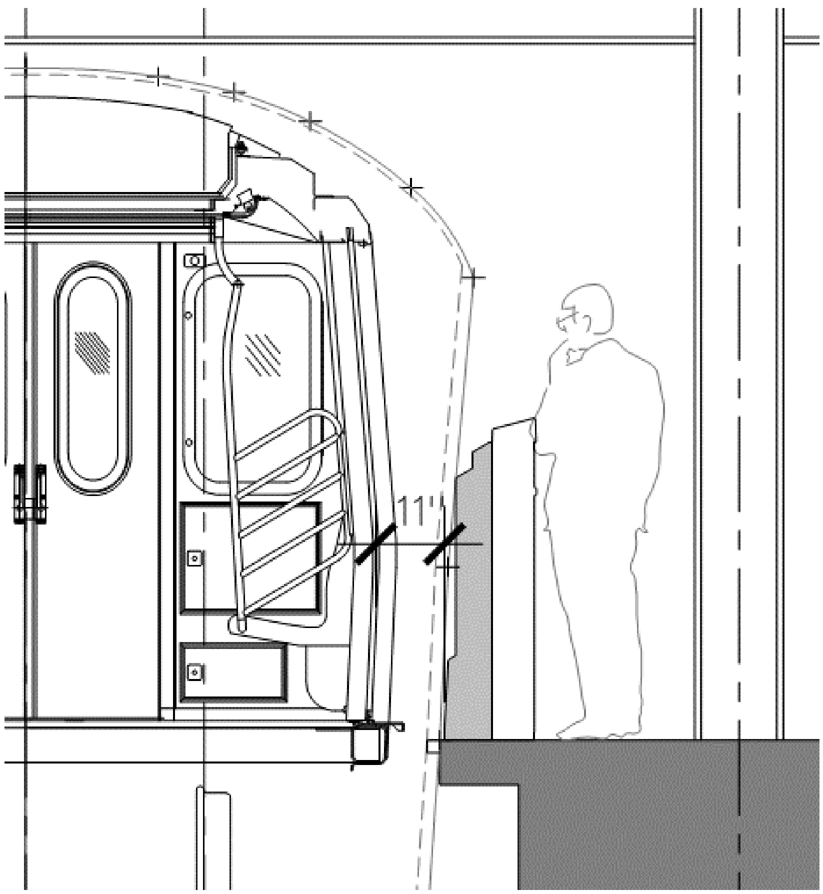

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

304 Turning Space

304.1 General. Turning space shall comply with 304.

304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.

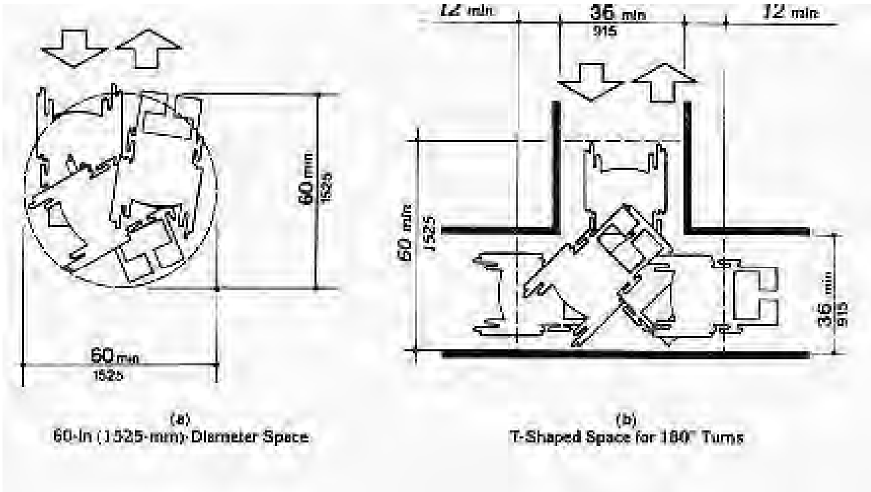
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

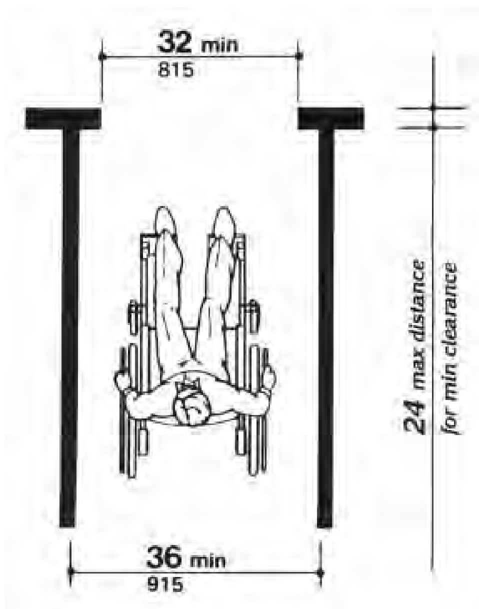


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

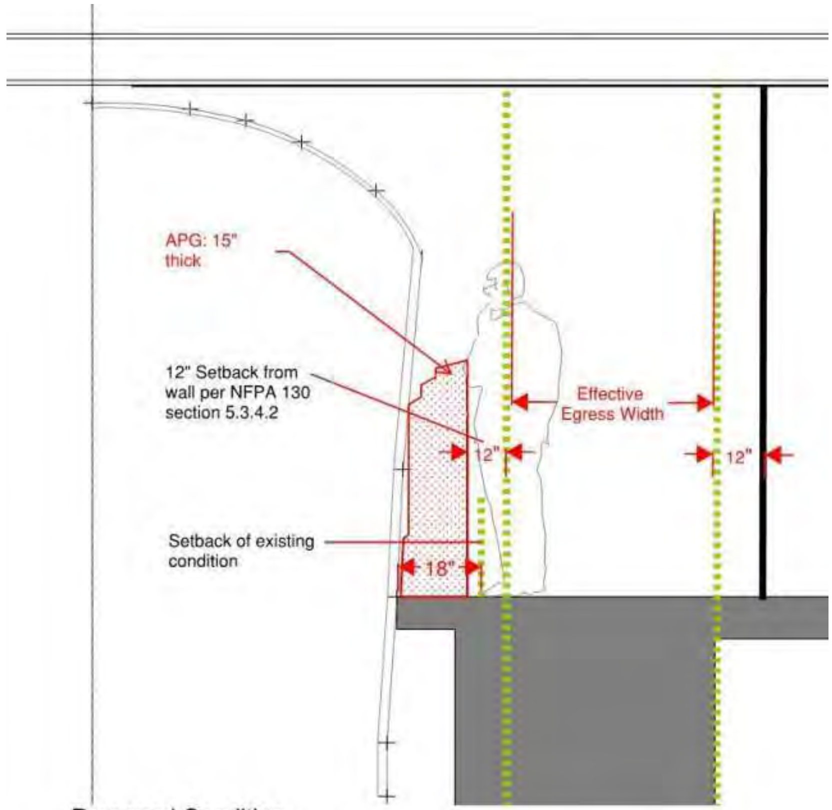
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Table of Contents | Appendix Table of Contents

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	**CBTC**		**Dedicated loop**		**Wayside only**	
		Qty.	**subtotal**	**Qty.**	**subtotal**	**Qty.**	**subtotal**
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

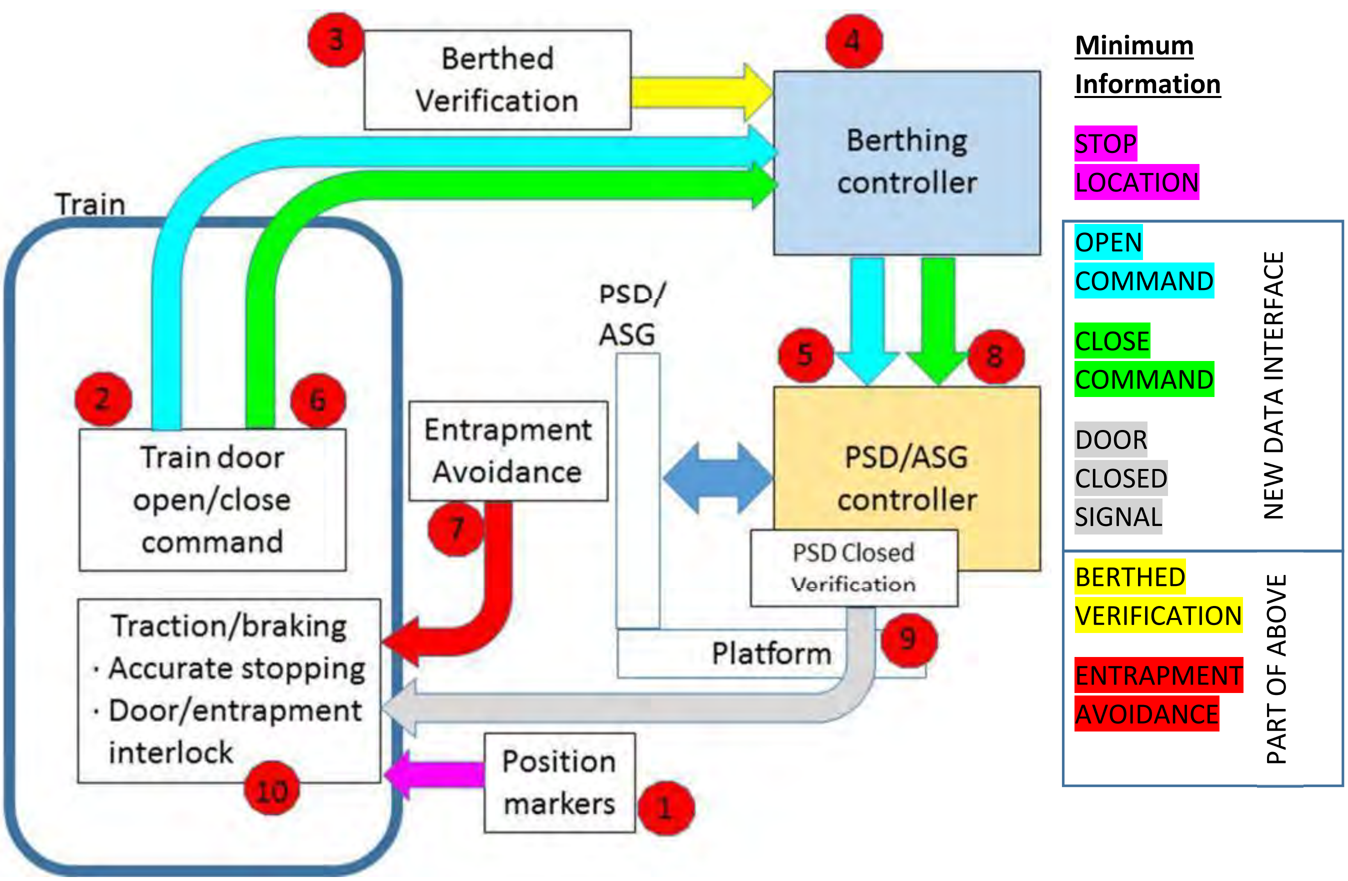
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

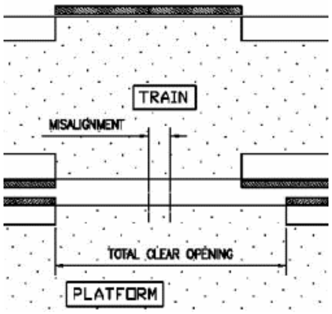
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

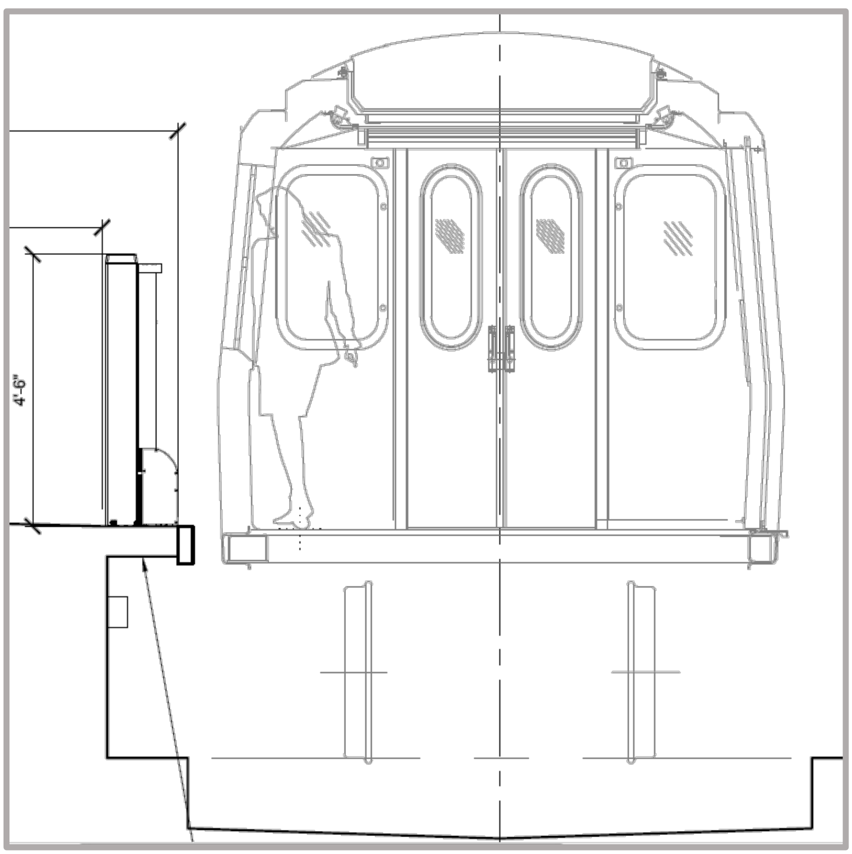


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1’-2” over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

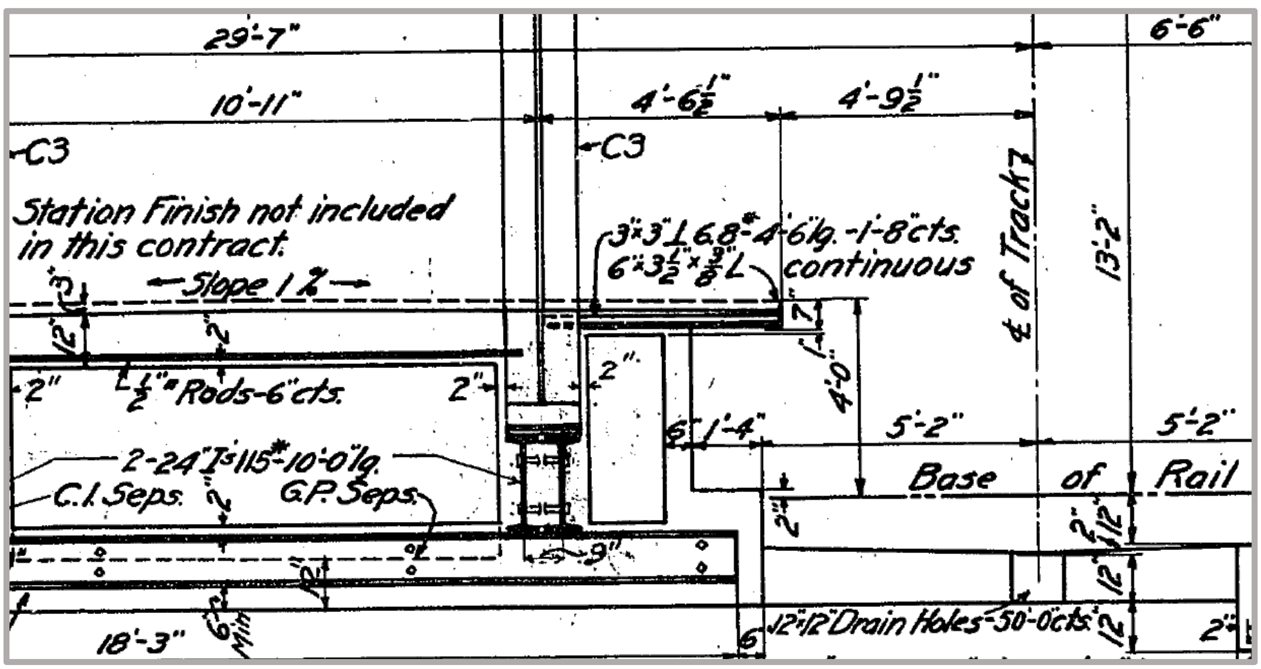

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; “2” & “5” Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6” thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1’-2” long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

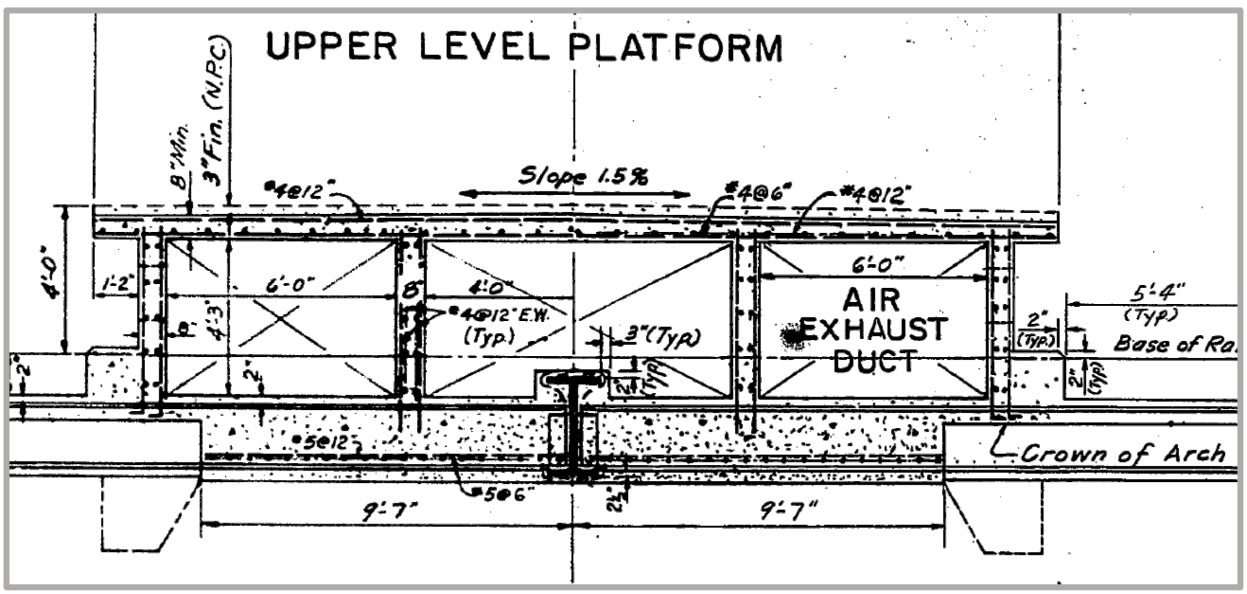

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; “E”, “J”, and “Z” trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

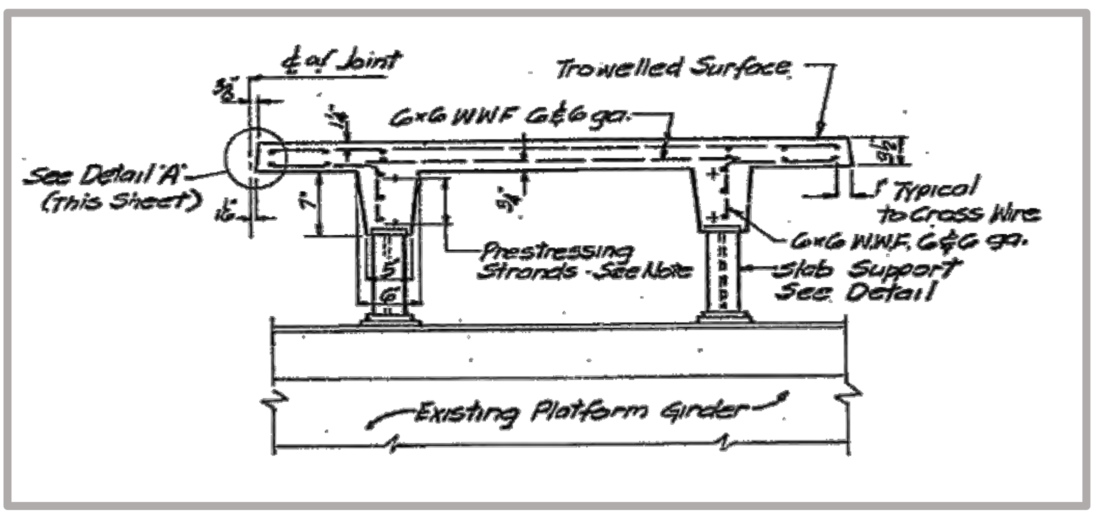

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

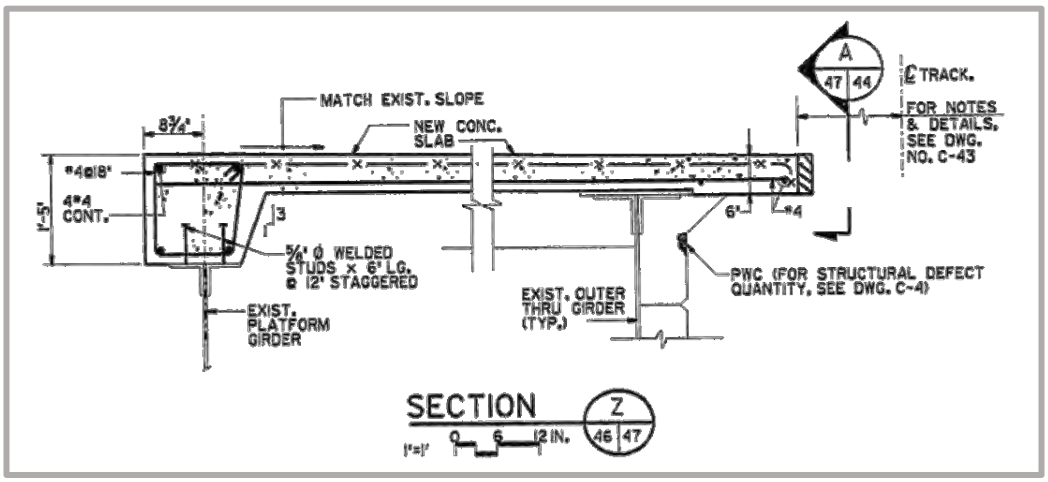

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

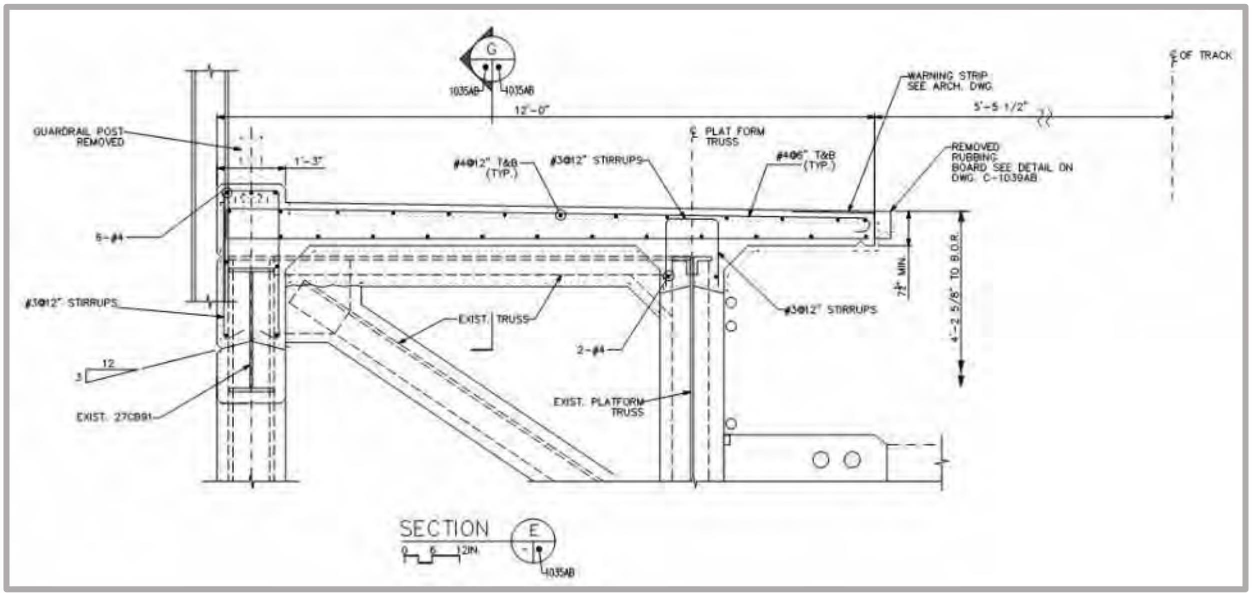

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

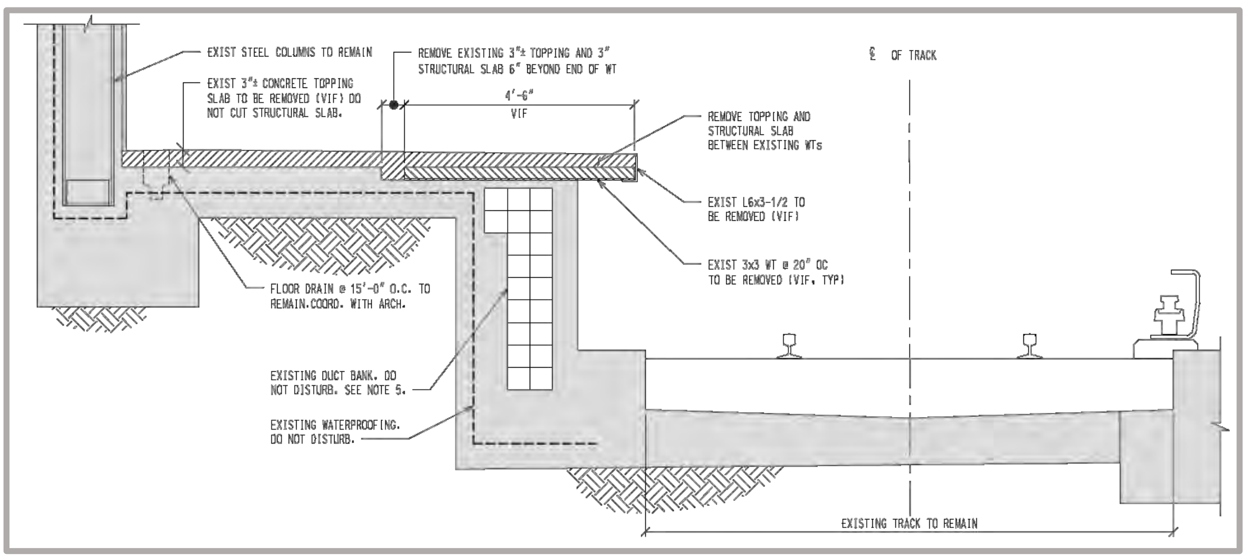

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

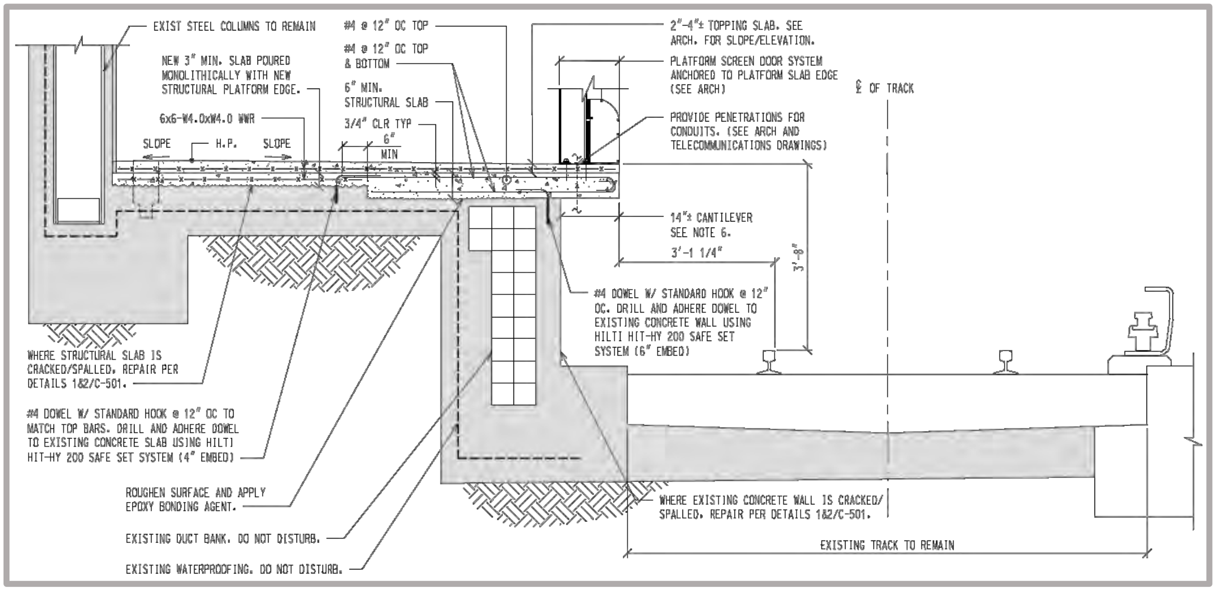

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

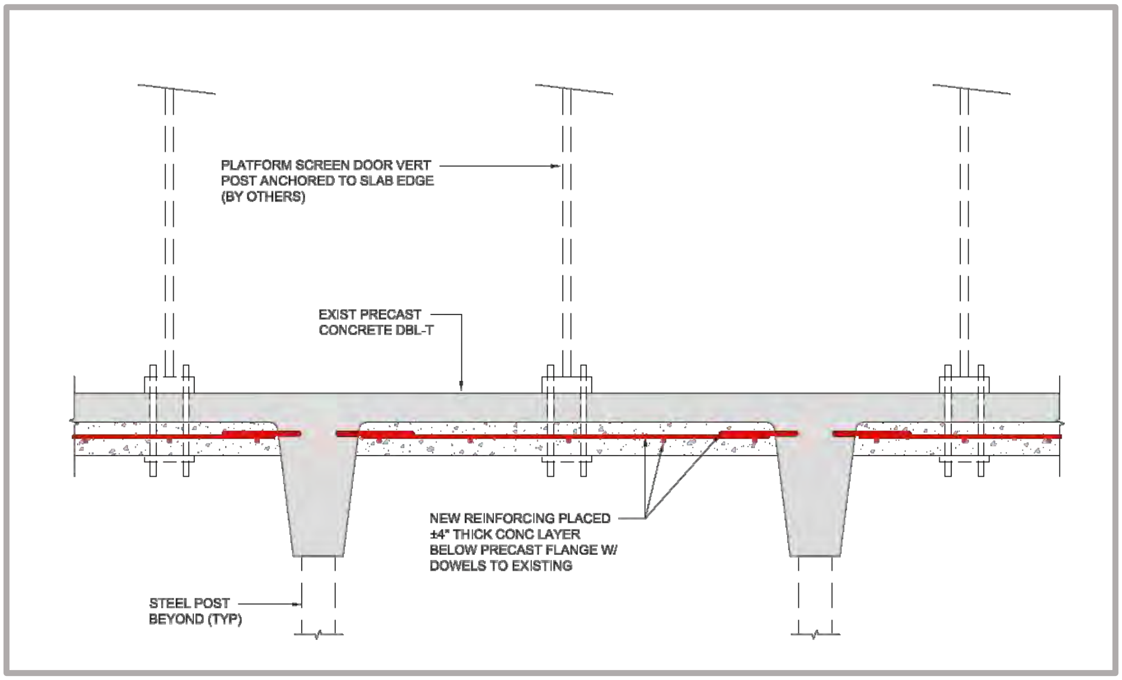

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5’ – 11” of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-2 Line Stations

MTA/NYCT

February 20, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-2 Line Stations

MTA/NYCT

February 20, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or “soft” costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-2 Line Stations

20-Feb-19

STATION : CANAL STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	546	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	555	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,101**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,101	LF	7	7,707
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,505	SF	12	66,060
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	111	CY	2,500	277,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,103	EA	25	27,575
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,103	EA	25	27,575
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,101	LF	95	104,595
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	Platform edge finishes				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,101	LF	15	16,515
26	Remove existing platform tiles	1,101	LF	12	13,212
27	Sawcut existing topping concrete at perimeter of removal area	1,101	LF	5	5,505
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,606	SF	8	52,848
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	506	SF	8	4,051
30	New Work				
31	New concrete topping to match existing	1,101	SF	15	16,515

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-2 Line Stations

20-Feb-19

STATION : BERGEN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	512	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	512	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,024**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,024	LF	7	7,168
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,120	SF	12	61,440
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	103	CY	2,500	257,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,026	EA	25	25,650
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,026	EA	25	25,650
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,024	LF	95	97,280
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,024	LF	15	15,360
26	Remove existing platform tiles	1,024	LF	12	12,288
27	Sawcut existing topping concrete at perimeter of removal area	1,024	LF	5	5,120
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,144	SF	8	49,152
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,024	SF	15	15,360

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-2 Line Stations

20-Feb-19

STATION : STERLING STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	507	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	507	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,014**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,014	LF	7	7,098
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,070	SF	12	60,840
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	102	CY	2,500	255,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,016	EA	25	25,400
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,016	EA	25	25,400
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,014	LF	95	96,330
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,014	LF	15	15,210
26	Remove existing platform tiles	1,014	LF	12	12,168
27	Sawcut existing topping concrete at perimeter of removal area	1,014	LF	5	5,070
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,084	SF	8	48,672
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,014	SF	15	15,210

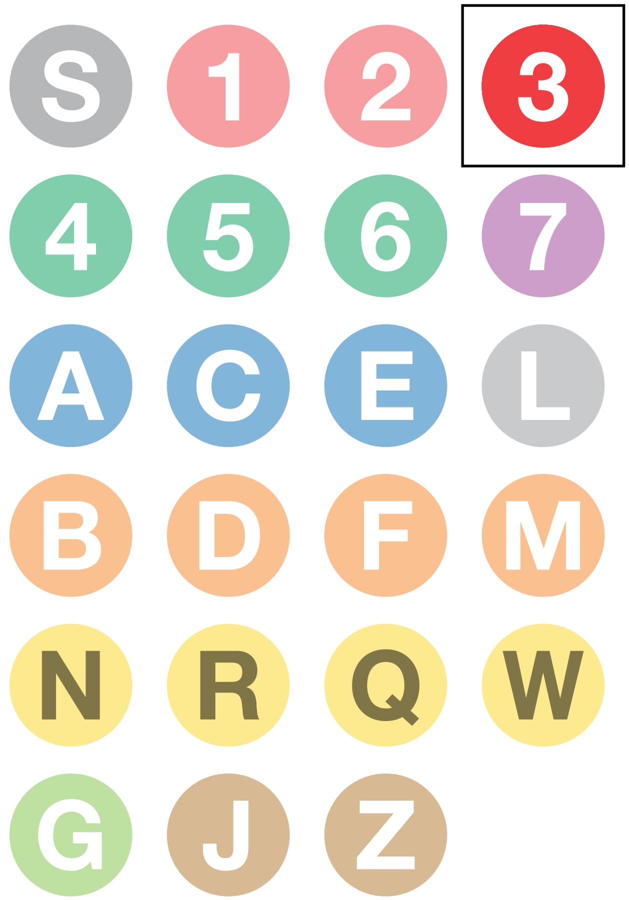
MTA New York City Transit



REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR '3' SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: April 3, 2019

STV 100 Years

Table of Contents

<u>Appendices</u>
Appendix A- Tier 2-3 Technology Assessment
Appendix B- Structural Feasibility
Appendix C- Emergency Egress Width Analysis
Appendix D- Maintenance Cost Estimates
Appendix E- ROM Cost Estimates

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 34 newly evaluated stations, 33 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at twenty-seven of the 3-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 3% of the '3' Line stations. Total implementation cost would be $26.9M for APGs and $33.2M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 1 feasible station, the aggregate annual maintenance cost would be $931,000.

Summary Table

(3% Feasible 1/34)

1.0 Station Assessments

1.01 – MR 310 | 96th Street Station

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 96th Street Station is a below-grade station with two straight center/ island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 13'-6' to 17'-8". The corridor width at this station's elevators is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
96th Street Station

1.02 – MR 313 | 72nd Street Station

Summary: *72nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met at five platform stairs as the remaining width would be 15" (see figure 1).*

Description

The 72nd Street Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 15'-6". The corridor width at the platform stairs is 30". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

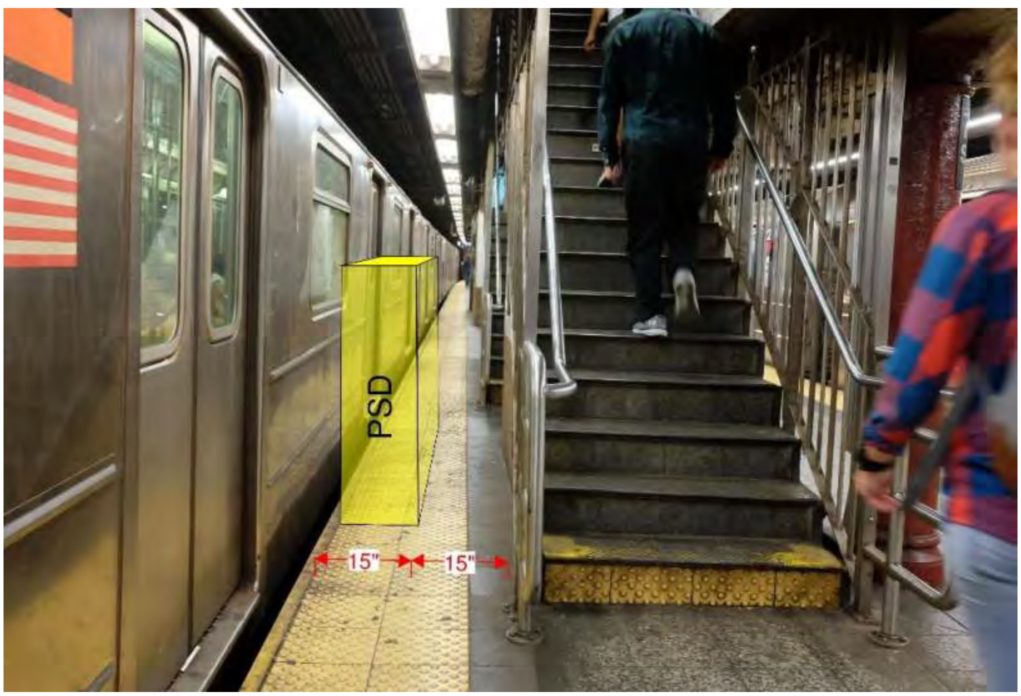

***Figure 1** – Non-compliant ADA condition*
72nd Street Station

1.03 – MR 317 | 42nd Street / Times Square Station

Summary: *42nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the south end of the platform as the remaining width would be 27" (see figure 1).*

Description

The 42nd Street Station is a below-grade station consisting two center / island platforms. The platforms are approximately 21'-2" wide throughout. At the southern end of the northbound platform there are 42" between the column and the platform edge. The implementation of a platform edge barrier would reduce this width to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
42nd Street Station

1.04 – MR 318 | 34th Street Penn Station

Summary: *34th Street Penn Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 5'-0" (see figure 1).*

Description

34th Street Station is a below-grade station consisting of both side and center / island platform. The express 2 and 3 trains utilize the center / island platform. The platform is approximately 24'-8"' wide throughout, narrowing to 5'-0" at the south end of the southbound platform and 5'-3" at the northbound platform. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress via emergency exit doors with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
34th Street Station

1.05 – MR 322 | 14th Street Station

Summary: *14th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-0"" (see figure 1).*

Description

14th Street Station is a below-grade station with two straight center/ island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 19'-4".

Platform width at the southern end of both platforms is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
14th Street Station

1.06 – MR 327 | Chambers Street Station

Summary: *Chambers Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Chambers Street Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 17'-2". The corridor width at the southern end of the southbound platform is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Chambers Street Station

1.07 – MR 331 | Park Place Station

Summary: *Park Place Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the escalator as the remaining width would be 23" (see figure 1).*

Description

The Park Place Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 17'-10". At the columns on either side of the escalator, there is 38" clearance. The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Park Place Station

1.08 – MR 332 | Fulton St. Station

Summary: *Fulton St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Fulton Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 13'-6" throughout. At the south end of the southbound platform, the existing clearance is 46". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Fulton Street Station

1.09 – MR 333 | Wall Street Station

Summary: *Wall Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 17" (see figure 1).*

Description

The Wall Street Station is a below-grade station with one center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 14'-0", narrowing to 6'-6" at the end. At several of the stairs, the existing clearance is 32". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 17" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

It is also not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
Wall Street Station

1.10 – MR 334 | Clark Street Station

Summary: *Clark Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at all stairs as the remaining width would be 9" (see figure 1)..*

Description

Clark Street Station is a below-grade station with one center / Island platform. The platform structure is cast in place concrete. The width of the platform is approximately 15'-6. At the two stairs, columns flanking the stairs leave 24" of clearance. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 9" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Clark Street Station

1.11 – MR 335 | Borough Hall Station

Summary: *Borough Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 23" (see figure 1).*

Description

Borough Hall Station is a below-grade station with two straight side platforms. The platform structures are cast in place concrete. The width of the platforms varies from 3'-2" to 11'- 8". At the south end of the southbound platform the corridor width to the platform wall is only 3'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

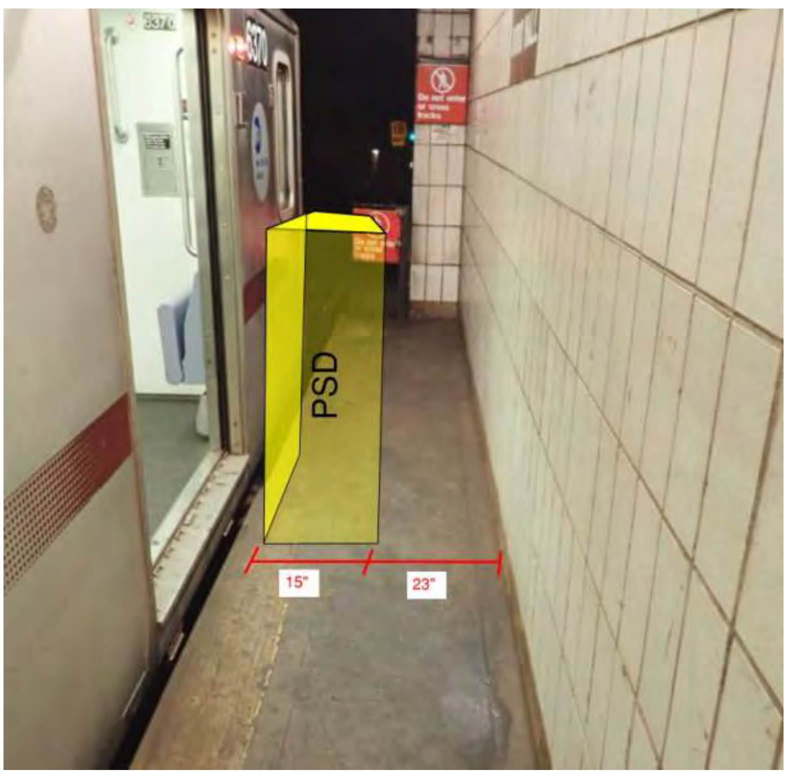

Figure 1 *– Non-compliant ADA condition*
Borough Hall Station

1.12 – MR 336 | Hoyt Street Station

Summary: *Hoyt Street Station is not feasible for both APGs and PSDs. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the north end of the northbound as the remaining width would be 19" (see figure 1)..*

Description

Hoyt Street Station is a below-grade station with two straight side platforms. The platform structures are cast in place concrete. The width of the platforms varies from 11'-0" to 13'- 0, and narrows at the ends. At the north end of the northbound platform, the existing clearance at the columns is 34". The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 19" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

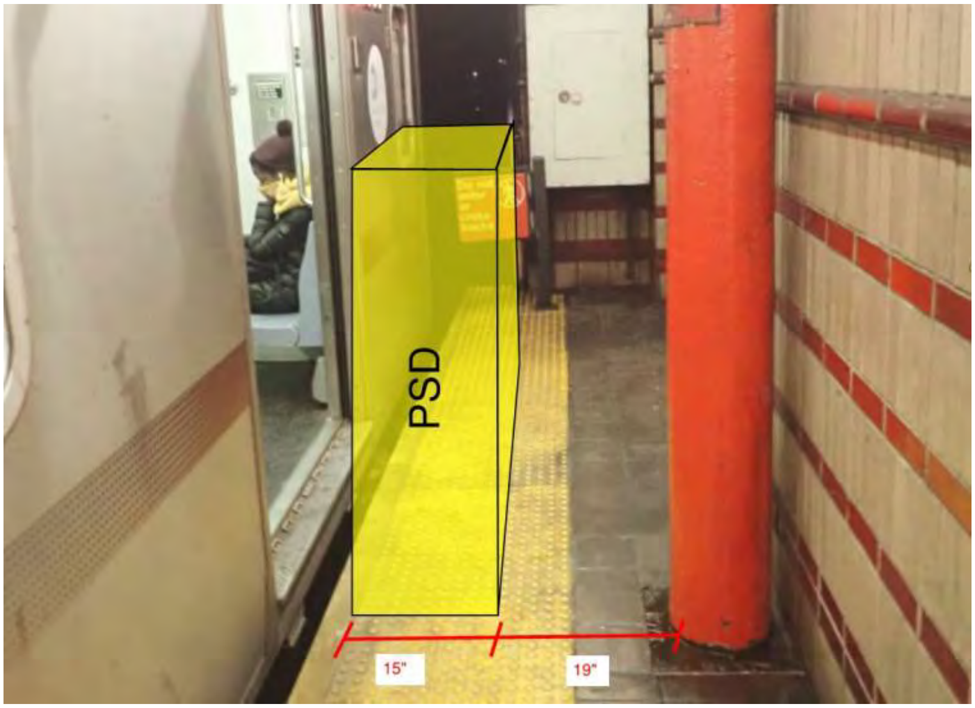

Figure 1 *– Non-compliant ADA condition*
Hoyt Street Station

1.13 – MR 337 | Nevins Street Station

Summary: *Nevins Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description

Nevins Street Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios

Figure 1 *– Columns at 20" from platform edge*
Nevins Street Station

.

1.14 – MR 338 | Atlantic Avenue Barclay Ctr Station

Summary: *Atlantic Avenue Barclay Ctr. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

The Atlantic Avenue Barclay Ctr. Station is a below-grade station with two straight side platforms and a center / island platform. The 3 trains stop at the side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 6'-8' to 18'-0". The corridor width at the staircase at the south end of the southbound platform is 36". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The non-compliant condition noted above could be remedied by moving the stopping location of the train. The proposal to move the stopping position of trains in specific stations would need to be studied by NYCT Signals Engineering to determine the impact to signals and signals equipment between that station and a series of adjacent stations all the way to the nearest interlocking. In many cases signals equipment at several locations would need to be relocated and rewired. The only way to fully determine this is to make an analysis of the existing signals system in that area.

Since that type of task is outside the scope of the PSD Feasibility Study, it is concluded that the current train stopping position is fixed. Given this condition, the ADA and/or Code analysis is being used for the feasibility analysis.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Atlantic Ave Station

1.15 – MR 339 | Bergen Street Station

Summary: *Bergen Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bergen Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located only at the center of the platforms along the platform edge. Column faces measure approximately 3'-8" from the platform edge. The platform widths are approximately 7-10" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

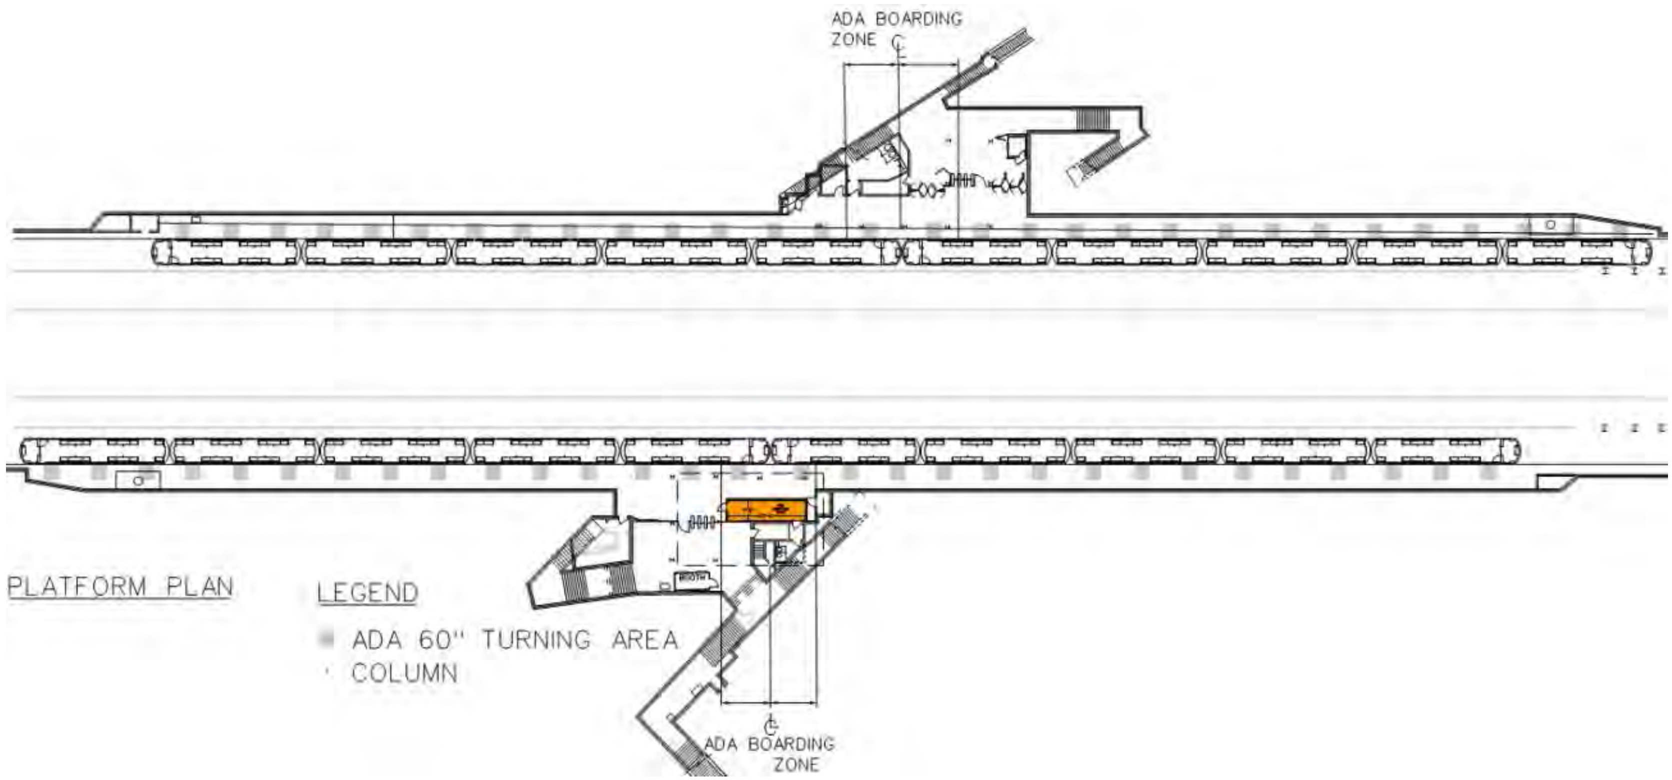

***Figure 1** – Overall Station Plan*
Bergen Street Station

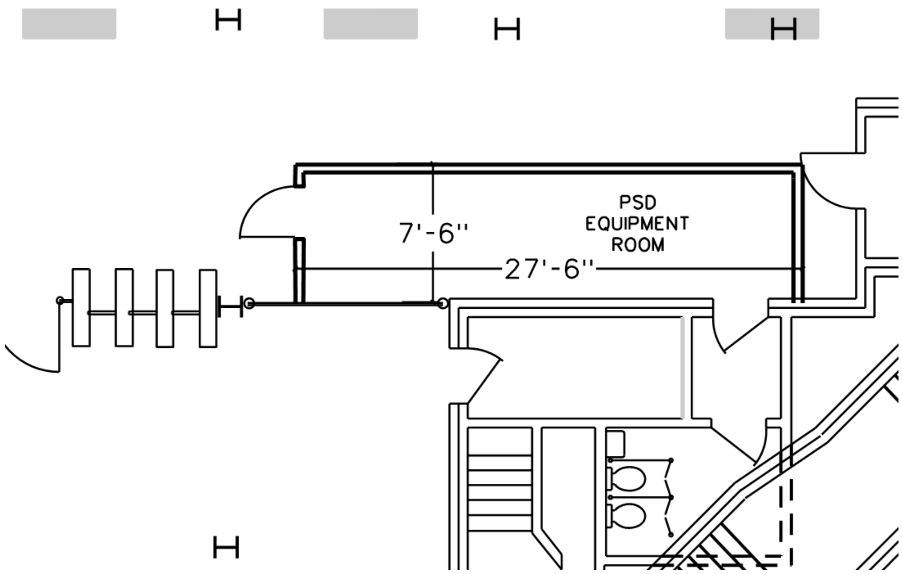

Figure 2 *– PSD Equipment Room 1 Detail*
Bergen Street Station

Figure 3 *– Typical platform view*
Bergen Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1, please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (normal service)

Station Name	Bergen Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	40.8
Apparent Power (kVA)	51.0
Station Peak Demand Load, Max Current, (A)	141.7
Maximum Amount of Doors	40.0
PSD Total Load Including All Miscellaneous Loads, (A)	121.6
Total Load (Station Peak + PSD), (A)	263
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	537
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram and observations of breaker schedule, showing 800A fuses at Service switch. The analysis is based on available Normal meter reading

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $26.9M to install APGs and $33.2M to install PSDs (See Appendix E)

1.16 – MR 340 | Grand Army Street Station

Summary: *Grand Army Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Grand Army Street Station is a below-grade station with one straight center/island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 32'-4" throughout. The corridor width at this station's western end is 44". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Grand Army Plaza Station

1.17 – MR 341 | Eastern Parkway Brooklyn Street Station

Summary: *Eastern Parkway Brooklyn Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-6" (see figure 1).*

Description

Eastern Parkway Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-6' to 11'-10".

Platform width at the ends of the platforms is 5'-6" or 66". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

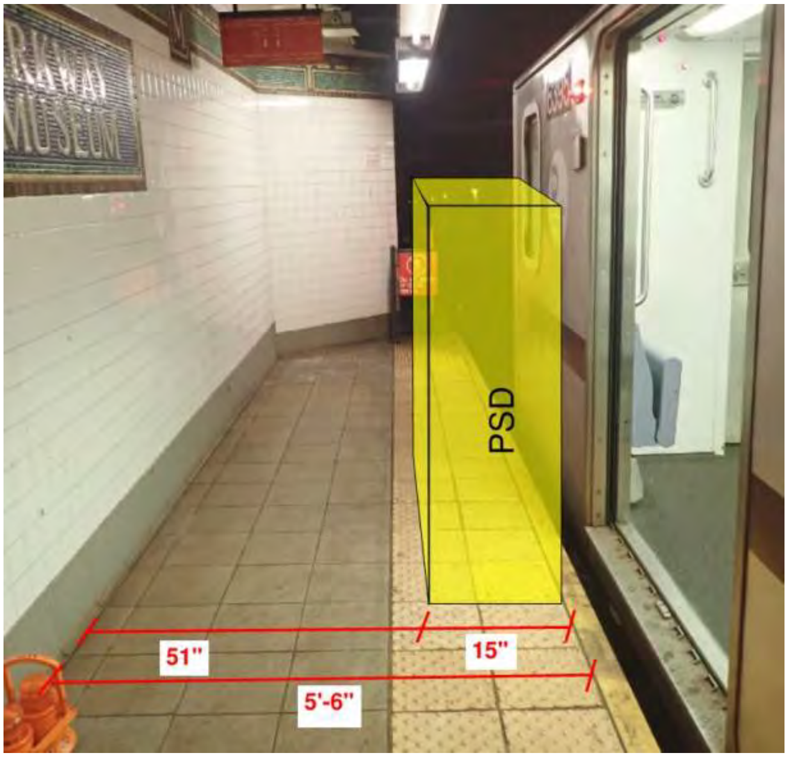

***Figure 1** – Non-Compliant egress condition*
Eastern Parkway Station

1.18 – MR 342 | Franklin Avenue Station

***Summary:** Franklin Avenue Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Franklin Avenue Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1 –** Column 16" from the edge*
Franklin Avenue Station

1.19 – MR 343 | Nostrand Avenue / Eastern Pkwy

Summary: *Nostrand Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Nostrand Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

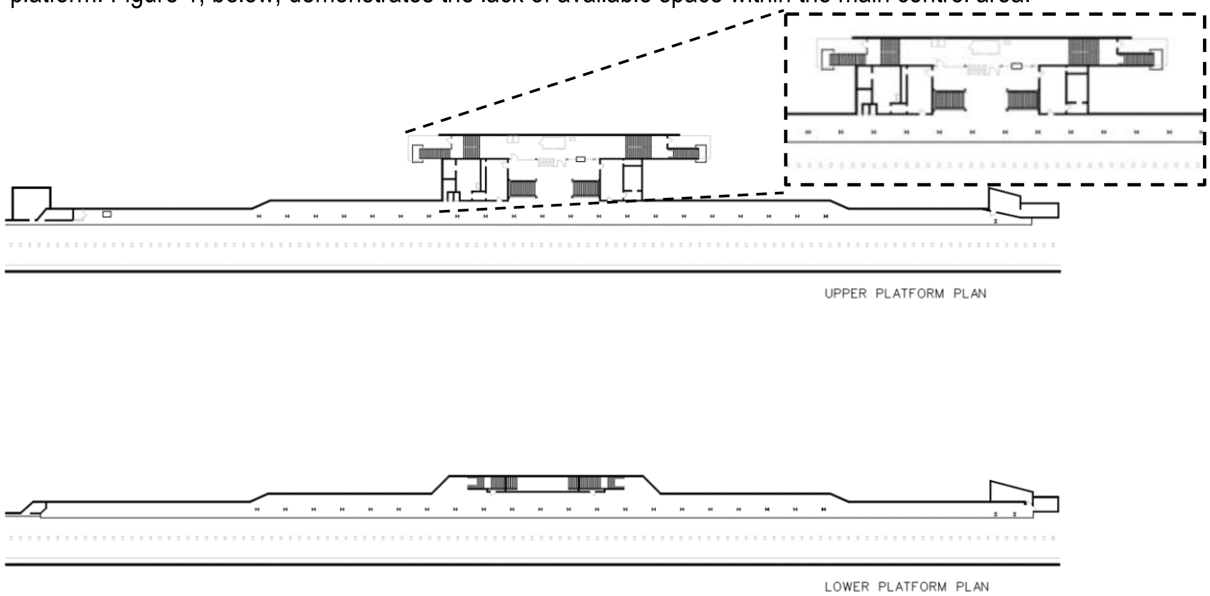

***Figure 1** – Congested/Narrow Station Plan*
Nostrand Avenue Eastern Pkwy

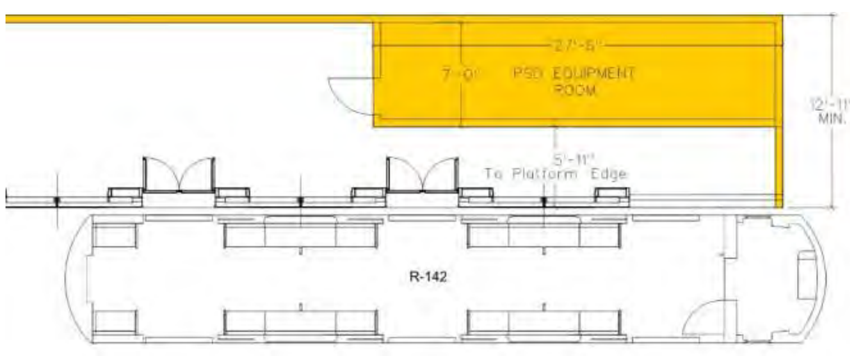

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.20 – MR 344 | Kingston Avenue

Summary: *Kingston Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Kingston Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

Kingston Avenue

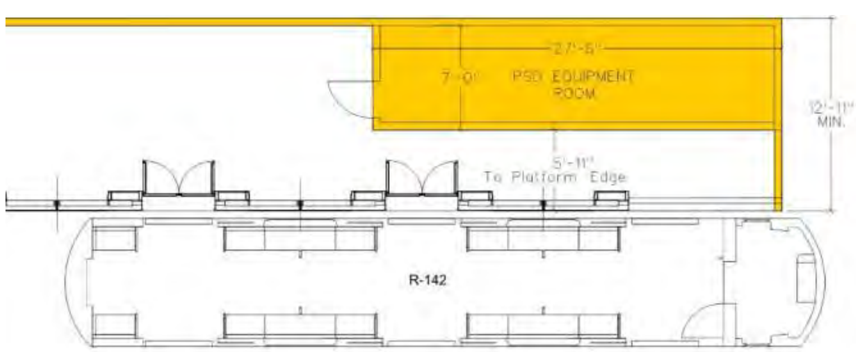

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.21 – MR 345 | Crown Heights / Utica Avenue

Summary: *Crown Heights Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede installation, access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Crown Heights Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge. This dimension does not allow for installation and maintenance of the 15"-wide APG/PSD system. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
Crown Heights Utica Avenue

1.22 – MR 346 | Sutter Avenue

Summary: *Sutter Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Sutter Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 8'-10" to 9'-10". The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Sutter Avenue Station

Rockaway Avenue Station

1.25 – MR 349 | Junius Street

Summary: *Junius Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Junius Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 9'-10" throughout. The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
Junius Street Station

***Figure 2** – Precast Slab*
Junius Street Station

1.26 – MR 350 | Pennsylvania Avenue

Summary: *Pennsylvania Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Pennsylvania Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 9'-10" throughout. The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Pennsylvania Avenue Station

Figure 2 *– Precast Slab*
Pennsylvania Avenue Station

1.27 – MR 351 | Van Siclen Avenue Station

Summary: *Van Siclen Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Van Siclen Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 9'-10" throughout. The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference..

Figure 1 *– General Station Condition*
Van Siclen Avenue Station

Figure 2 *– Precast Slab*
Van Siclen Avenue Station

1.28 – MR 352 | New Lots Avenue Station

Summary: *New Lots Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The New Lots Avenue Station is an elevated station with one center / island platform. The platform structure is precast concrete. The width of the platforms is approximately 15'-0" throughout. The platform is straight with one row of columns supporting the station canopy. See figure 1 for reference.

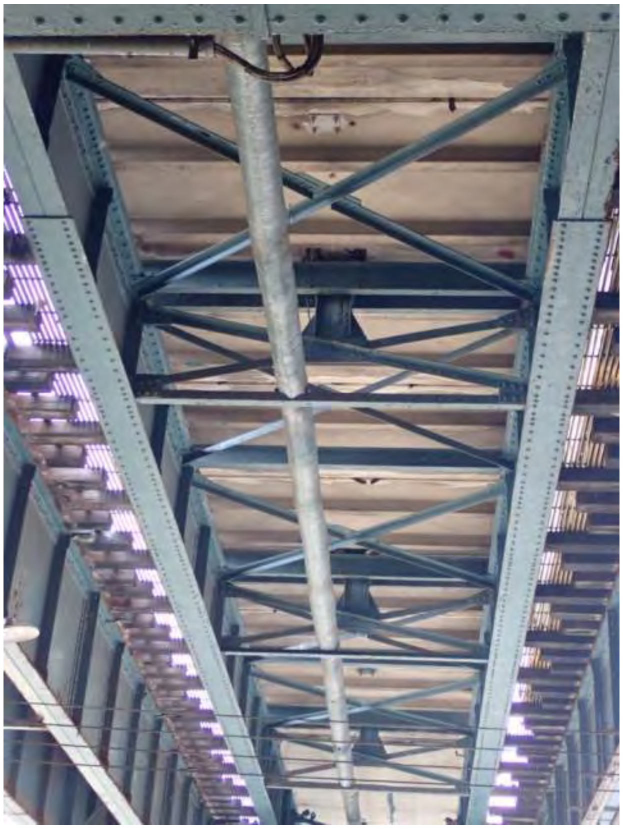

***Figure 1** – Precast Slab*
New Lots Avenue Station

1.29 – MR 436 | 148th Street Station

Summary: *148th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met at the south end of the platform as the remaining width would be 23" (see figure 1).*

Description

The 148th Street Station is an at-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 19'-4". The corridor width at the dispatcher's office is 38". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 23" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
148th Street Station

1.30 – MR 437 | 145th Street Station

Summary: *145th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 4'-0"" (see figure 1).*

Description

145th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-0' to 12'-10".

Platform width at the southern end of both platforms is 4'-0" or 48". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

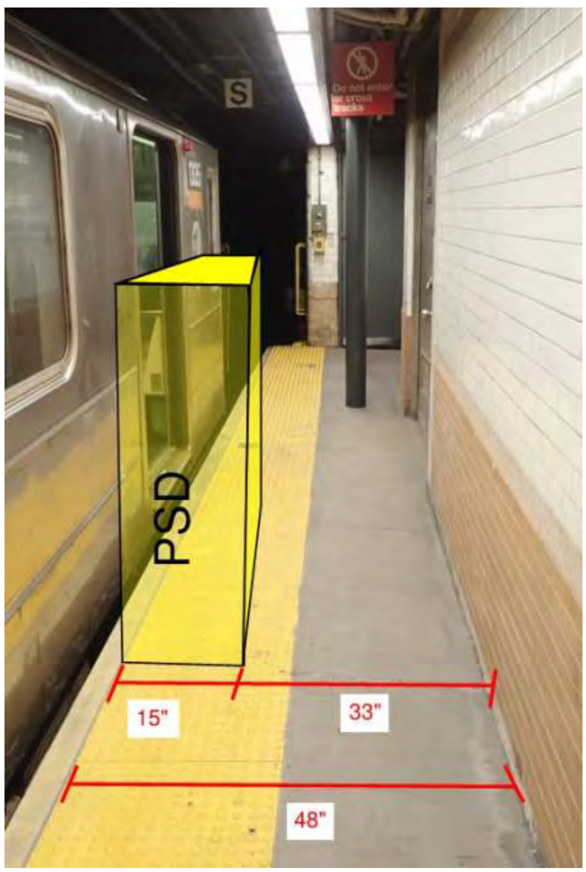

***Figure 1** – Non-compliant ADA condition*
145th Street Station

1.31 – MR 438 | 135th Street

Summary: *135th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

135th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

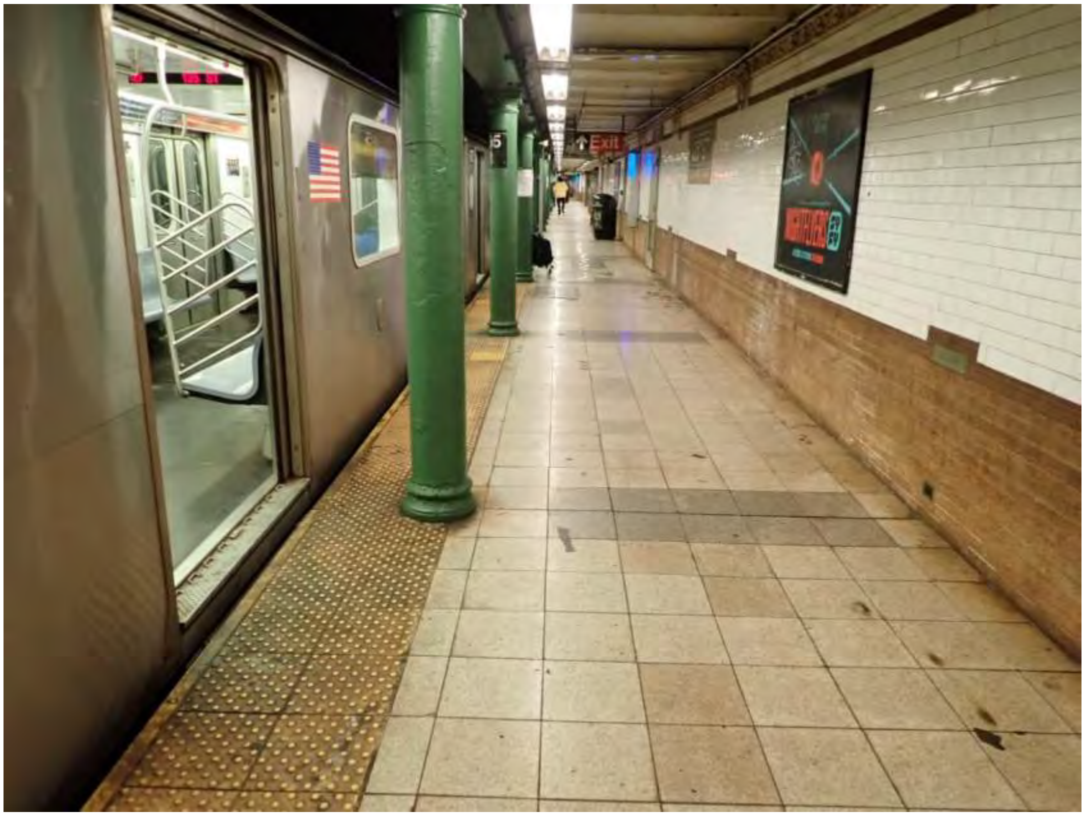

Figure 1 – *Column 16" from the edge*
135th Street Station

1.32 – MR 439 | 125th Street

Summary: *125th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede installation, access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

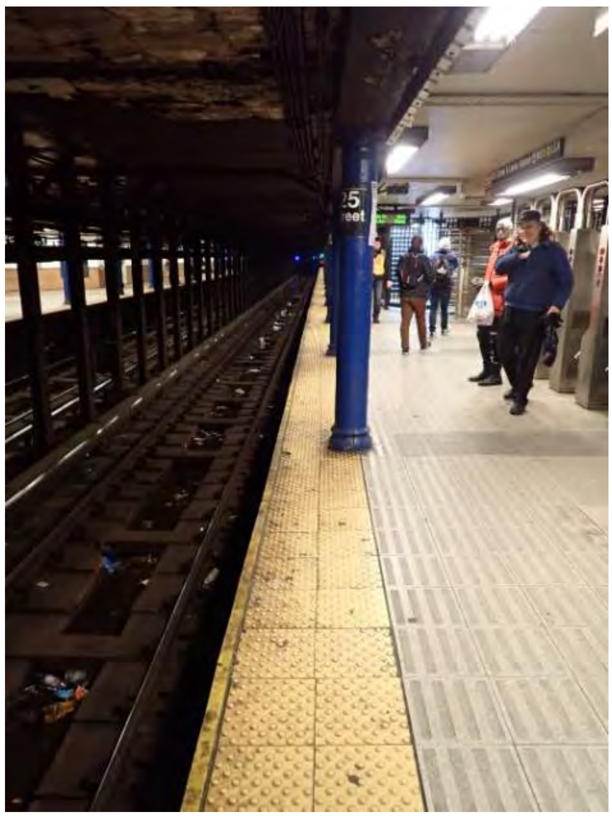

***Figure 1 –** Column 16" from the edge*
125th Street Station

1.33 – MR 440 | 116th Street Station

Summary: *116th Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede installation, access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

116th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
116th Street Station

1.34 – MR 441 | 110th Street Station

Summary: *110th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-0" (see figure 1).*

Description

110th Street Station is a below-grade station with one center / island platform. The platform structure is cast-in-place concrete. The width of the platform varies from 5'-0'" to 20'-0".

The corridor width at the center of this platform adjacent to the control area is constrained to o 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
   - Double the amount of motors as PSDs (each motor operating a single leaf).
   - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
   - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
   - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

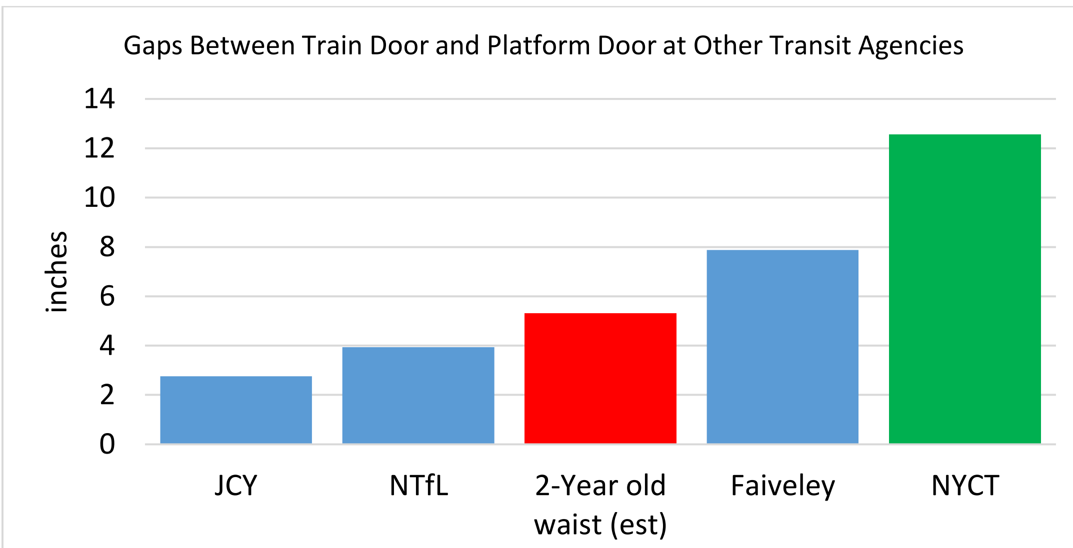

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

 *Figure 3 - Paris: no entrapment detection*	 *Figure 4 - Paris: no entrapment detection*	 *Figure 5 - France ATO: no entrapment detection*
 *Figure 6 - Paris, on curve: used 3 2D scanning lasers per door*	 *Figure 7 - Shanghai: End of platform light detection*	 *Figure 8 - Seoul: Platform observers*

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

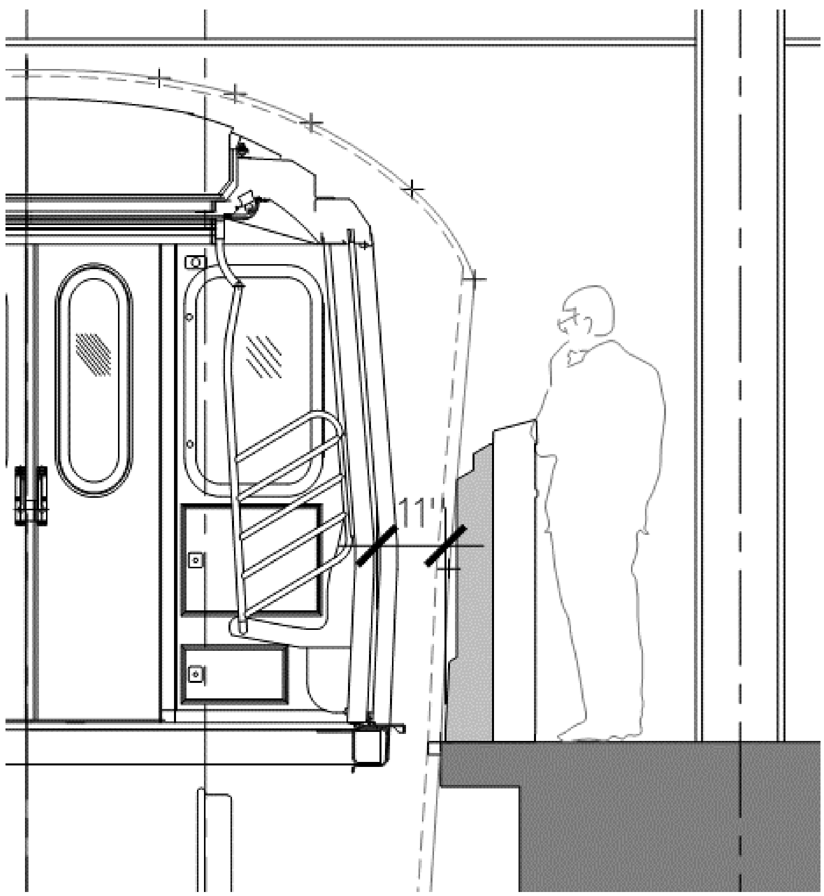

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

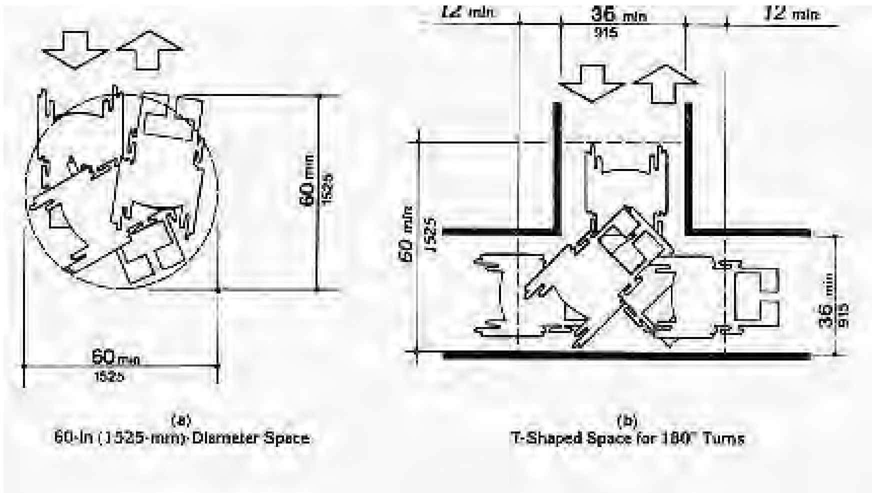
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

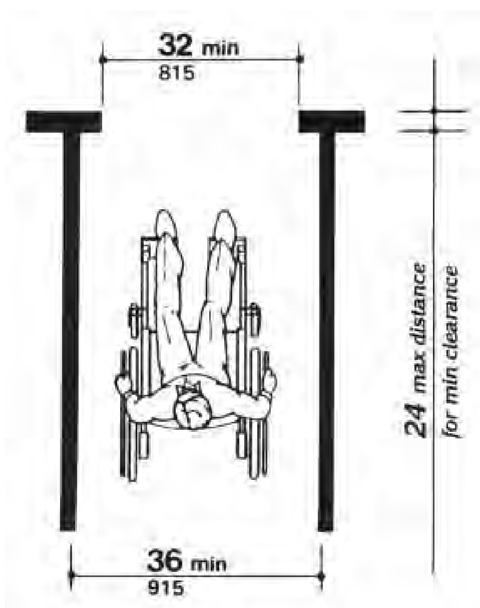


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

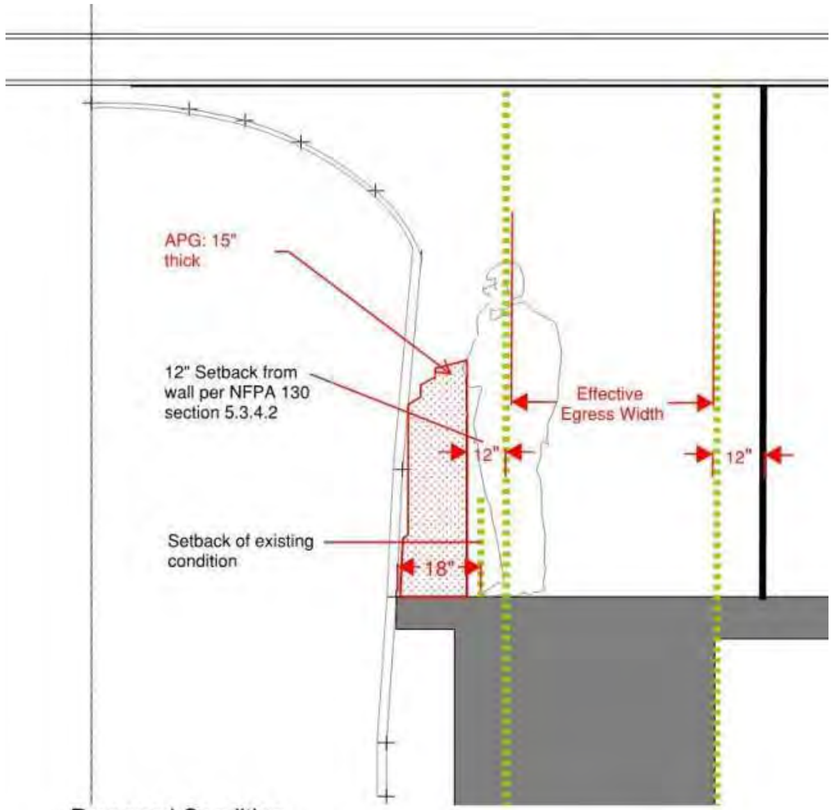
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

End of Appendix

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

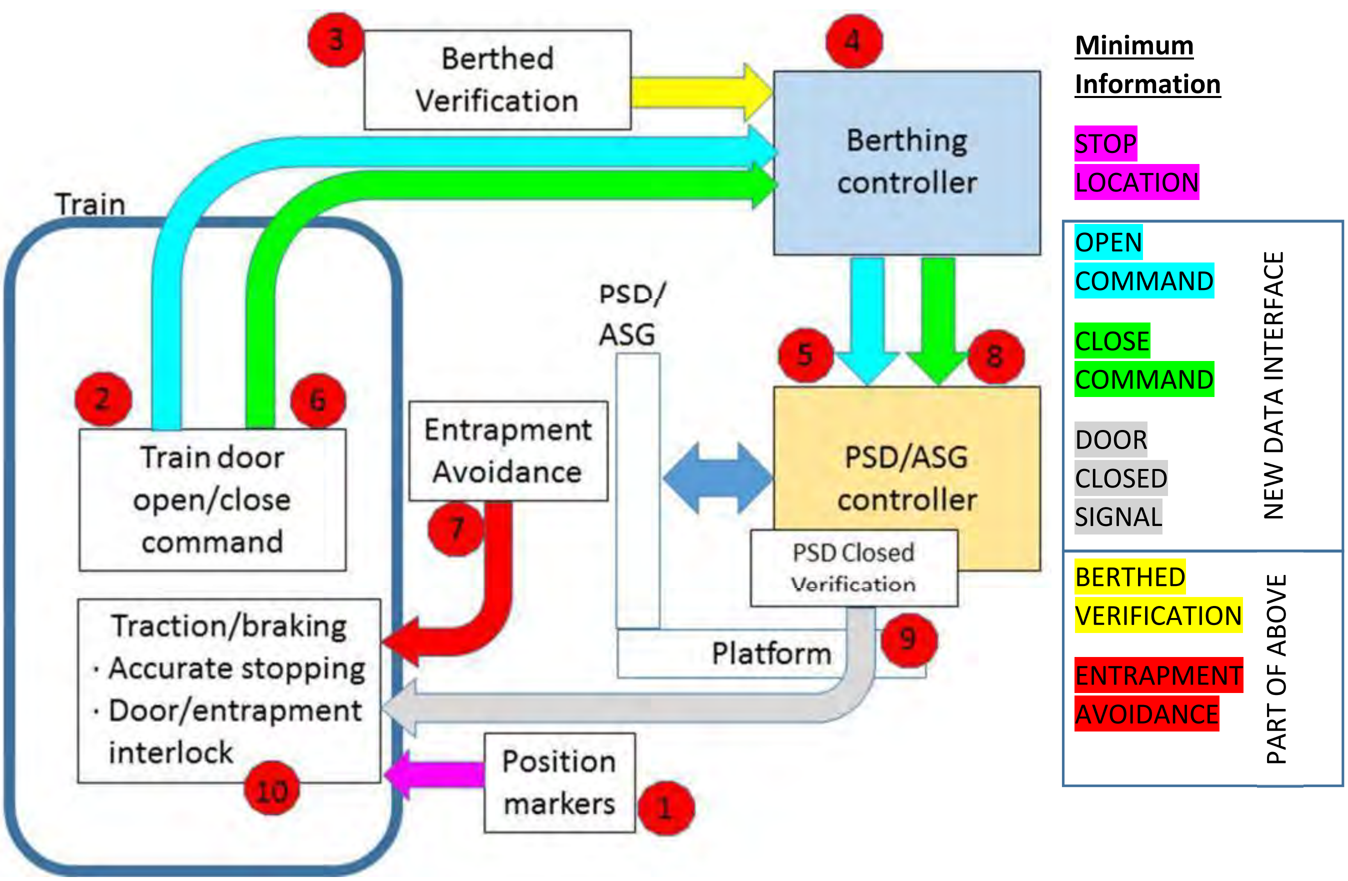
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

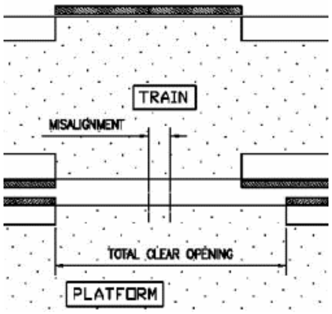
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command, Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

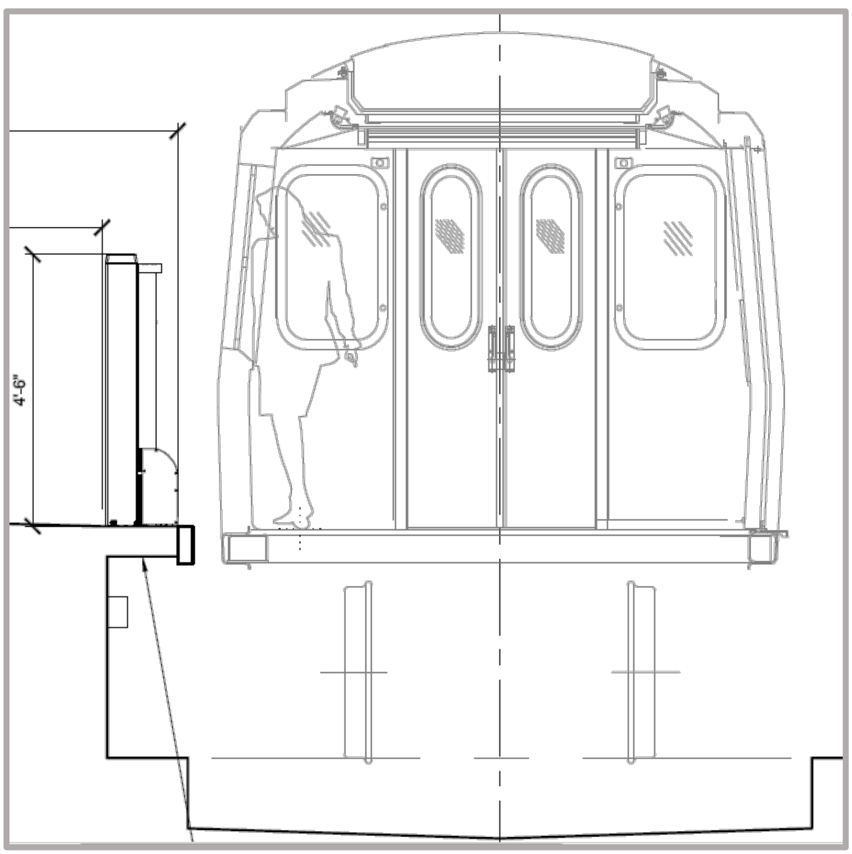


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

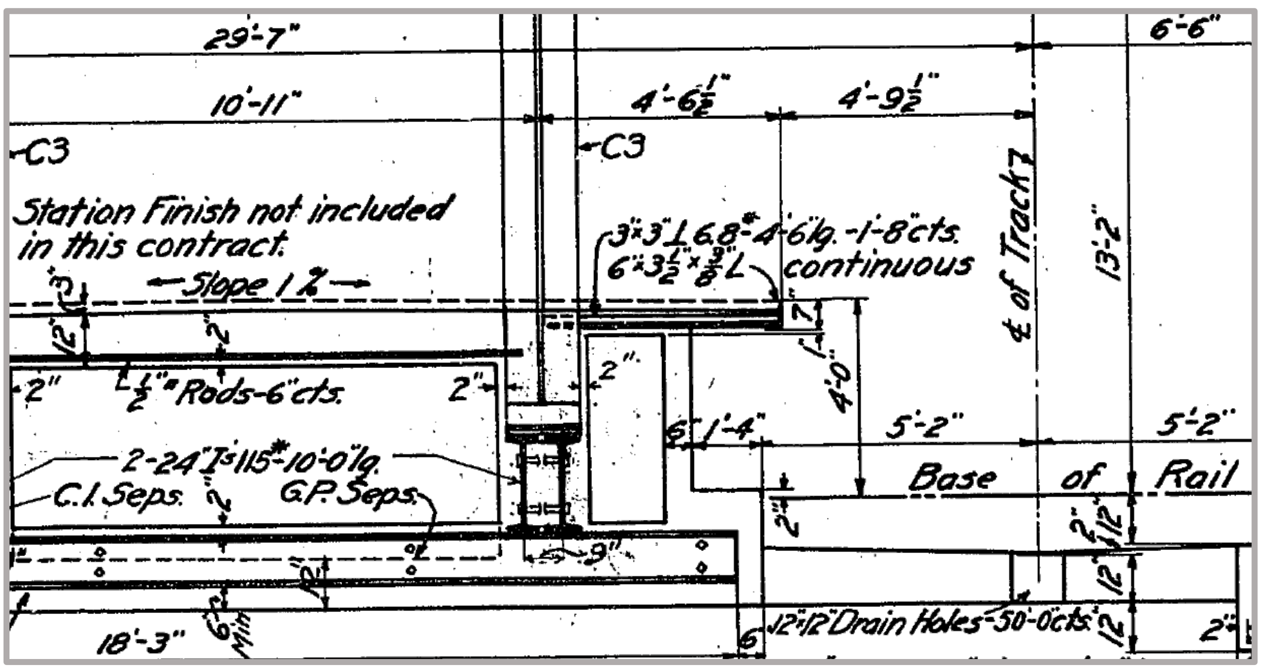

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

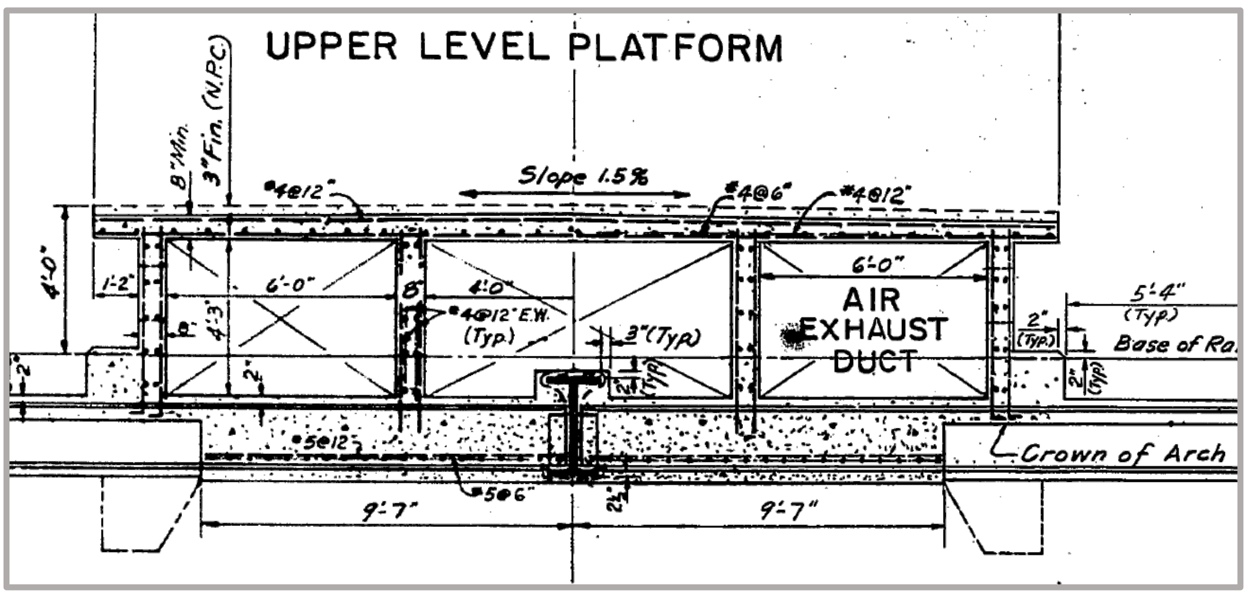

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

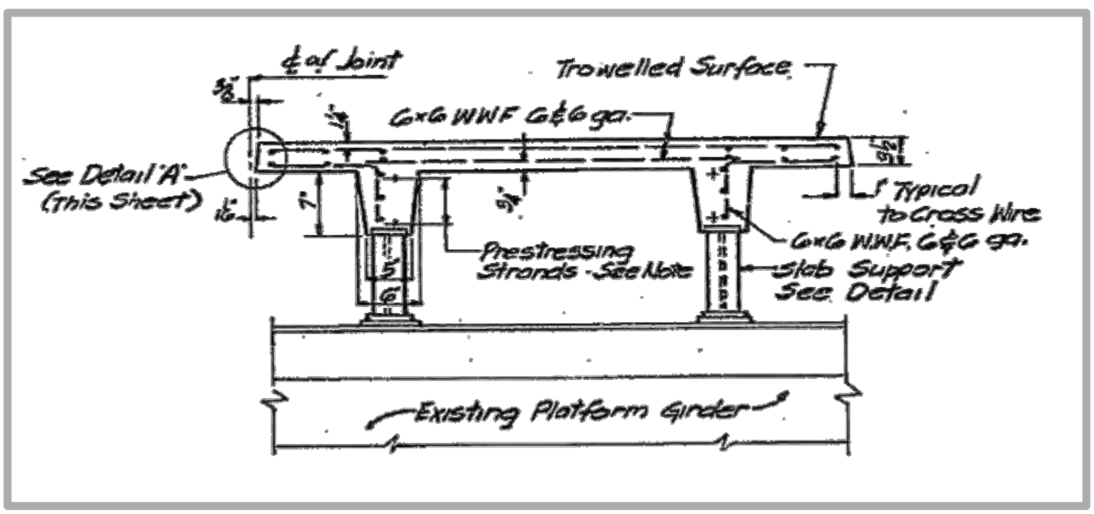

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

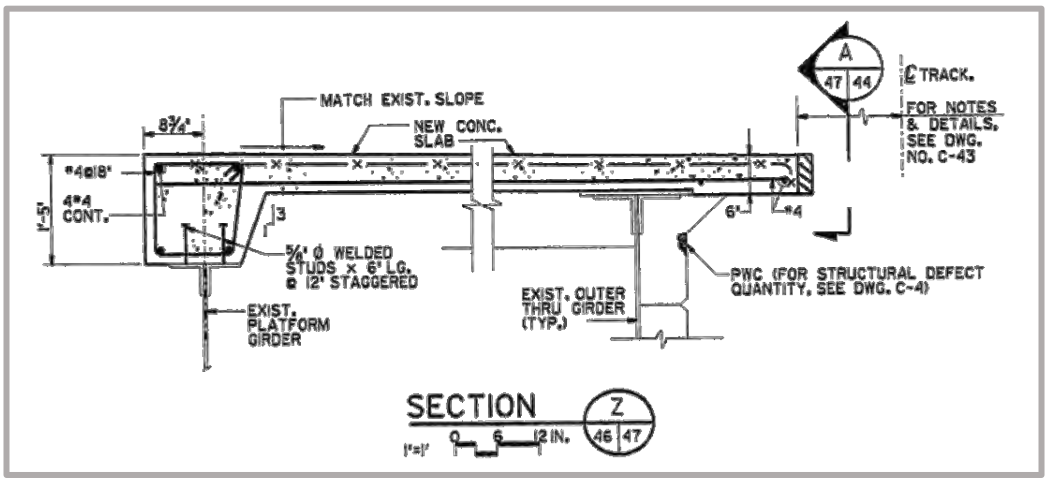

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

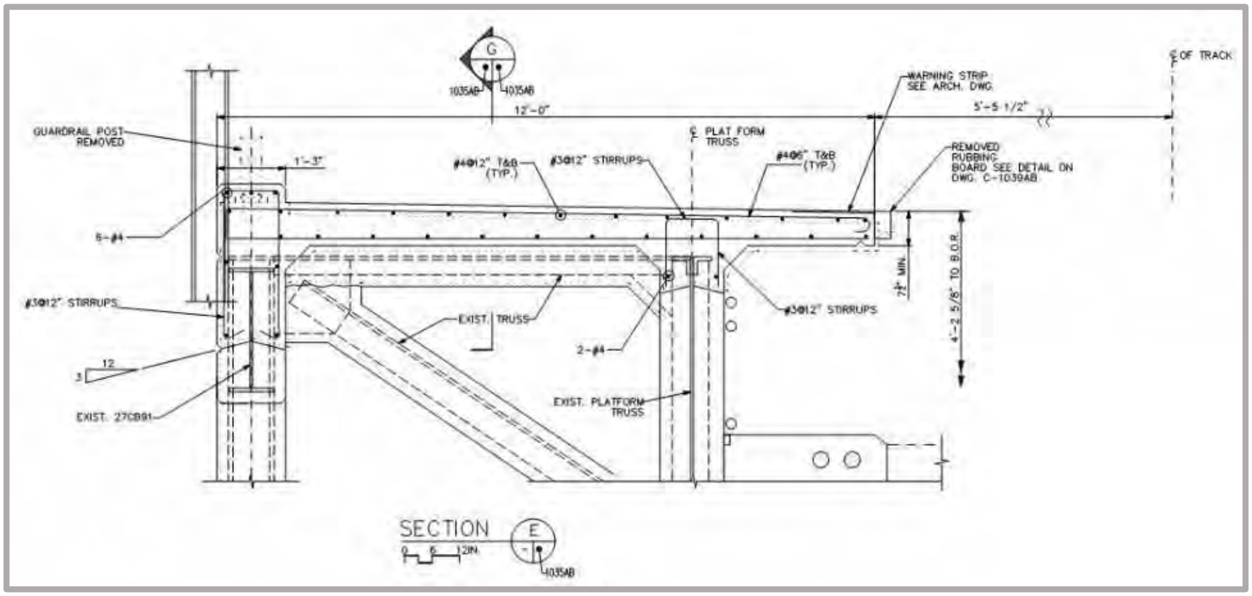

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

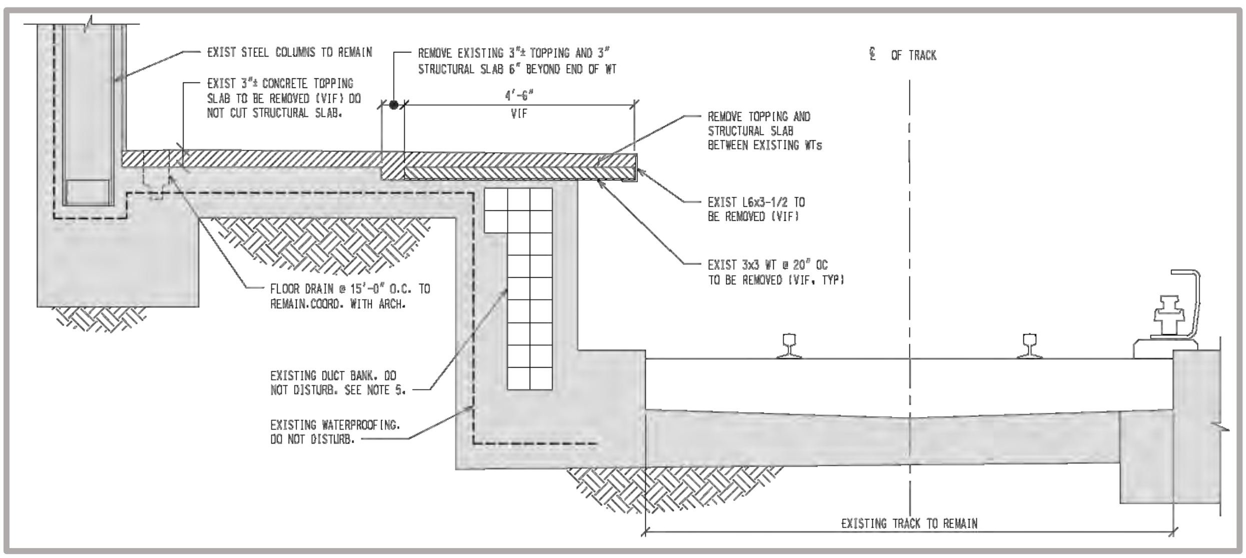

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

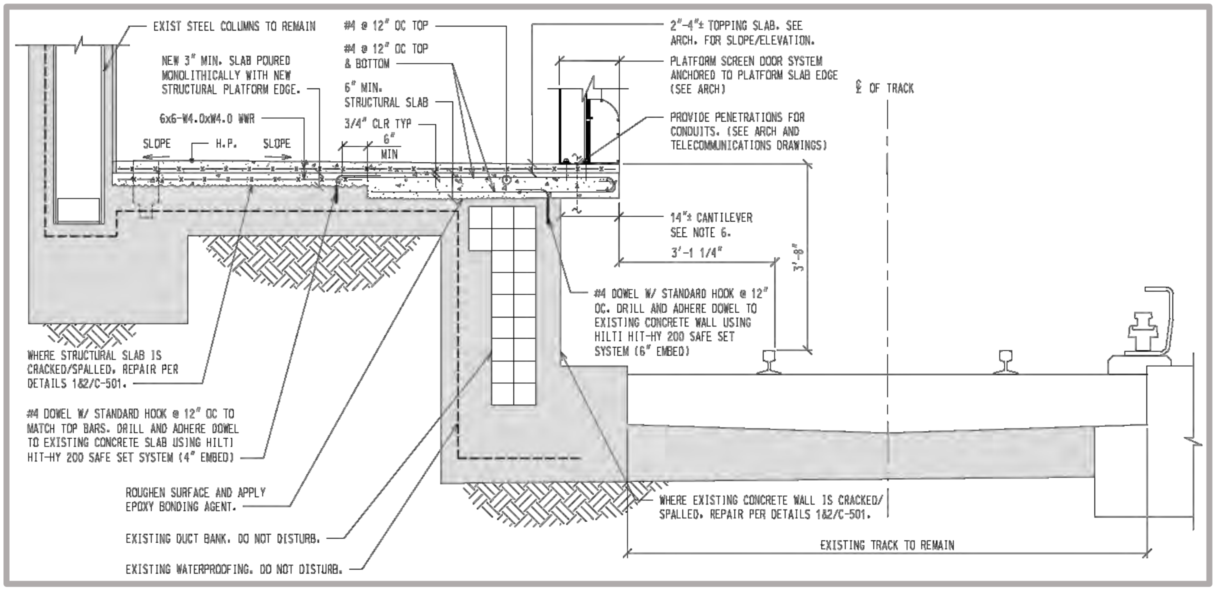

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

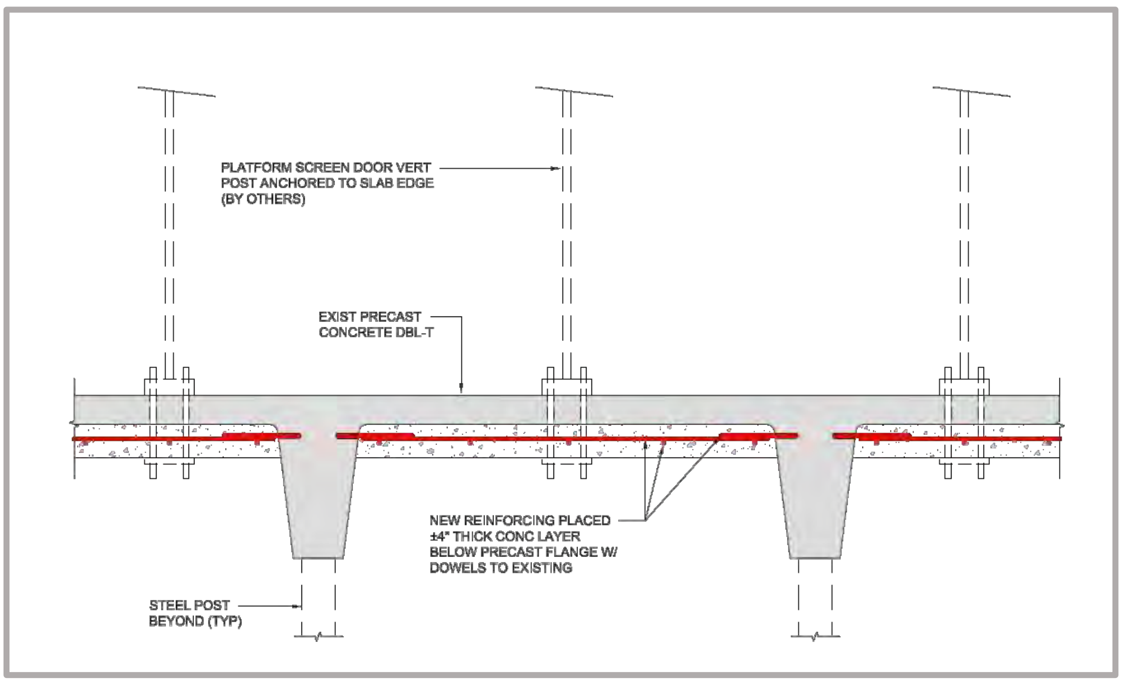

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

PRICING SCHEDULE WITH OPTION FOR EXTENDED TERM OF MAINTENANCE / SOFTWARE SUPPORT

ITEM NO.	DESCRIPTION	ESTIMATE QUANTITY	RATE	EXTENDED AMOUNT	SUB-TOT 01 OPTION 3.2	SUB-TOT 01 OPTION 3.1
1	First 90 days - 24-7 full time presence on site (including daily cleaning of glass)	90	$ 4,800 per Day	$ 432,000		
	Materials and labor for preventative maintenance and remedial repair performed as needed, 24/7, for the platform screen door system and ancillary equipment. Price for year 1 is intended for preventive maintenance since remedial maintenance and repairs will be covered by the warranty period. Should warranty period be longer for the System or some of its components, price should not include items covered by warranty.	9	$ 63,500 per month [Year 01]	$ 571,500		
		12	$ 83,590 per month [Year 02]	$ 1,003,080		
		12	$ 65,683 per month [Year 03]	$ 788,196	$ 2,794,776	$ 2,794,776
2	Training for 100 workers - 20 / session; 16 HRS per session	5	$ 13,000 per session	$ 65,000	$ 65,000	$ 65,000
3.1	Optional Maintenance for years 4 & 5 (OPTION 1)	Year 4-5				
	Materials and labor for preventative maintenance and remedial repair performed as needed, 24/7, for the platform screen door system and ancillary equipment.	12	$ 68,310 per month [Year 04]	$ 819,724		$ 819,724
		12	$ 71,043 per month [Year 05]	$ 852,513		$ 852,513
3.2	Optional Maintenance for years 4 & 5 (OPTION 2)	Year 4-5				
	Repair and Replacement of Defective Hardware	24	$ 6,350 per month	$ 76,200		
	Technical Assistance [4 Hrs per Month]	24	$ 880 per month	$ 10,560		
	As Needed On-Site Support [1 Day per Month]	192	$ 220 per Hour	$ 2,640		
	Software / Firmware Support	2	$ 3,500 per Year	$ 42,000	$ 131,400	$ -
4	Optional Maintenance for years 6-10	Year 6-10				
	Repair and Replacement of Defective Hardware	60	$ 9,525 per month	$ 571,500		
	Technical Assistance [4 Hrs per Month]	60	$ 920 per month	$ 55,200		
	As Needed On-Site Support [1 Day per Month]	480	$ 230 per Hour	$ 110,400		
	Software / Firmware Support	5	$ 3,750 per Year	$ 18,750	$ 755,850	$ 755,850
5	Optional Maintenance for years 11-15	Year 11-15				
	Repair and Replacement of Defective Hardware	60	$ 12,700 per month	$ 762,000		
	Technical Assistance [5 Hrs per Month]	60	$ 1,200 per month	$ 72,000		
	As Needed On-Site Support [1.5 Days per Month]	720	$ 240 per Hour	$ 172,800		
	Software / Firmware Support	5	$ 4,000 per Year	$ 20,000	$ 1,026,800	$ 1,026,800
6	Optional Maintenance for years 16-20	Year 16-20				
	Repair and Replacement of Defective Hardware	60	$ 15,875 per month	$ 952,500		
	Technical Assistance [6 Hrs per Month]	60	$ 1,500 per month	$ 90,000		
	As Needed On-Site Support [2 Days per Month]	960	$ 250 per Hour	$ 240,000		
	Software / Firmware Support	5	$ 4,500 per Year	$ 22,500	$ 1,305,000	$ 1,305,000
	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 2) [DEFAULT OPTION AS PER RFP DOCUMENTATION]		TOTAL:	$ 6,078,826	$ 6,078,826	$ 7,619,663

	TOTAL OPTIONAL MAINTENANCE YEARS 1 THRU 20 (ITEM 3 OPTION 1)		TOTAL:	$ 7,619,663

7	Labor Bill Rate (per hour)	Year 1	$ 238 per hour *	
	Task Orders (Rate in Effect 24/7/365)	Year 2	$ 248 per hour *	
		Year 3	$ 257 per hour *	
	Optional :	Year 4	$ 268 per hour *	
	Optional :	Year 5	$ 278 per hour *	

Note: Labor rate is deemed to include all relevant tax and insurance, medical, pension, vacation fund, etc., travel time to and from project site and night/shift/weekend/holiday work i.e. 24/7 Rate

* Labor rates include Contractor's Overhead & Profit and Insurance (Refer Annual Maintenance Cost Breakdown) and are escalated at 4% per annum

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-3 Line Stations

MTA/NYCT

February 20, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train- 3 Line Stations

MTA/NYCT

February 20, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-3 Line Stations

20-Feb-19

STATION : BERGEN STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	512	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	512	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,024**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,024	LF	7	7,168
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,120	SF	12	61,440
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	103	CY	2,500	257,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,026	EA	25	25,650
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,026	EA	25	25,650
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,024	LF	95	97,280
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,024	LF	15	15,360
26	Remove existing platform tiles	1,024	LF	12	12,288
27	Sawcut existing topping concrete at perimeter of removal area	1,024	LF	5	5,120
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,144	SF	8	49,152
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,024	SF	15	15,360

Table of Contents Appendix Table of Contents

STATION : BERGEN STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	560	SF	15	8,400
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	360	LF	110	39,600
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing platform slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 3 Doors = 30 No. per platform)	60	EA	15,000	900,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #29 per Platform	58	EA	10,500	609,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,133	SF	750	1,599,750
61	Spare Parts - Approx. 10% of Material Cost	1	LS	192,045	192,045
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	60	EA	2,500	150,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-3 Line Stations

20-Feb-19

STATION : BERGEN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,024	LF	60	61,440
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	200	LF	60	12,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	180	EA	4,629	833,263
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	180	EA	5,566	1,001,802
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR '4' SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: March 29, 2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 54 newly evaluated stations, 49 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the 4-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 9% of the '4' Line stations. Total implementation cost would be $136.6M for APGs and $170.6M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be $4.6M.

Summary Table

(9% Feasible 5/54)

MR No.	Station Names	Station Type	Platform Type	Feasibility	Issues/Reason for Failure	Cost APGs	Cost PSDs

1.0 Station Assessments

1.01 – MR 337 | Nevins Street Station

***Summary:** Nevins Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description

Nevins Street Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1** – Columns at 20" from platform edge*
Nevins Street Station

.

1.02 – MR 338 | Atlantic Avenue Barclay Center Station

Summary: *Atlantic Avenue Barclay Ctr. Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Atlantic Avenue Barclay Ctr. is a below-grade station consisting of one center / island platform (the No. 2&3 trains utilize separate side platforms). This report concerns only the No. 4&5 train platform. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Atlantic Avenue Barclay Ctr. Station

1.03 – MR 339 | Bergen Street Station

Summary: *Bergen Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bergen Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located only at the center of the platforms along the platform edge. Column faces measure approximately 3’-8” from the platform edge. The platform widths are approximately 7-10” throughout. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27’-6” x 7’-0”.

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

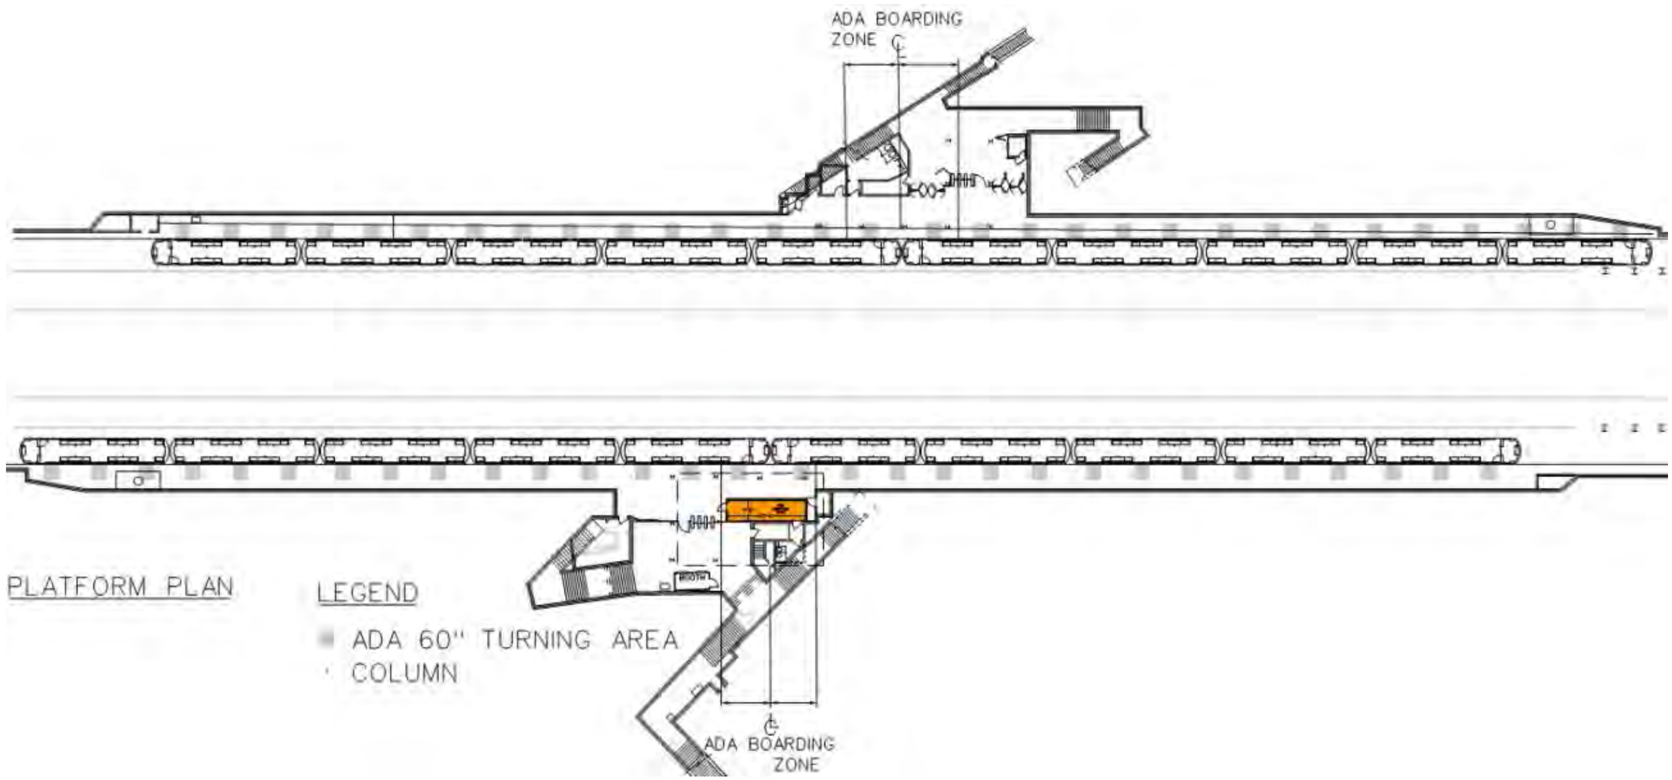

***Figure 1** – Overall Station Plan*
Bergen Street Station

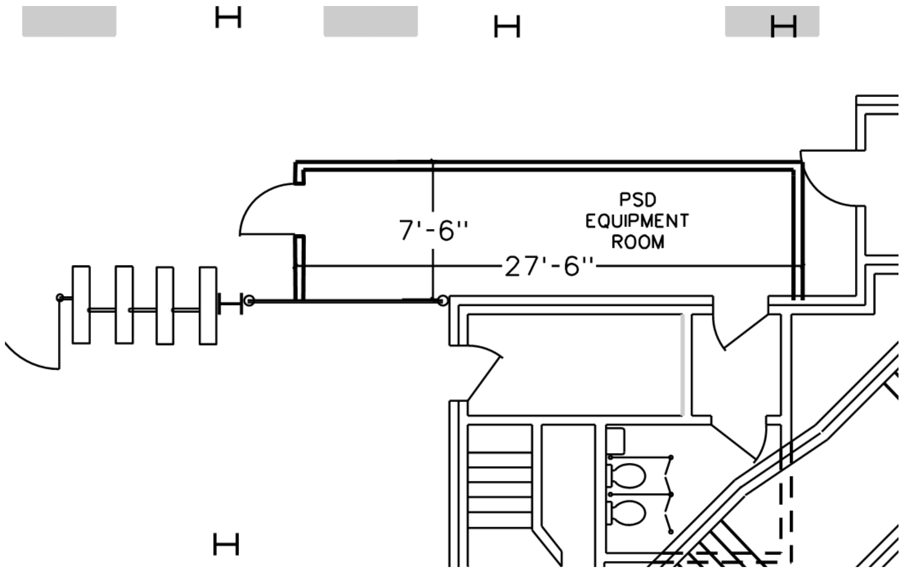

Figure 2 – *PSD Equipment Room 1 Detail*
Bergen Street Station

Figure 3 – *Typical platform view*
Bergen Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	Bergen Street
Peak Demand Load from ConEd Report, (kW)	40.8
Apparent Power (kVA)	51.0
Station Peak Demand Load, Max Current, (A)	141.7
Maximum Amount of Doors	40.0
PSD Total Load Including All Miscellaneous Loads, (A)	121.6
Total Load (Station Peak + PSD), (A)	263
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	537
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram, having 800A fuses at Service switch. The analysis is based on available Normal meter reading. (No access to Reserve room and no Reserve meter reading provided)

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $26.9M to install APGs and $33.3M to install PSDs (See Appendix E)

1.04 – MR 340 | Grand Army Plaza Station

Summary: *Grand Army Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Grand Army Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 32'-4" throughout. The corridor width at this station's western end is 44". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Grand Army Plaza Station

1.05 – MR 341 | Eastern Parkway Station

Summary: *Eastern Parkway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 5'-6" (see figure 1).*

Description

Eastern Parkway Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-6' to 11'-10".

Platform width at the ends of the platforms is 5'-6" or 66". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

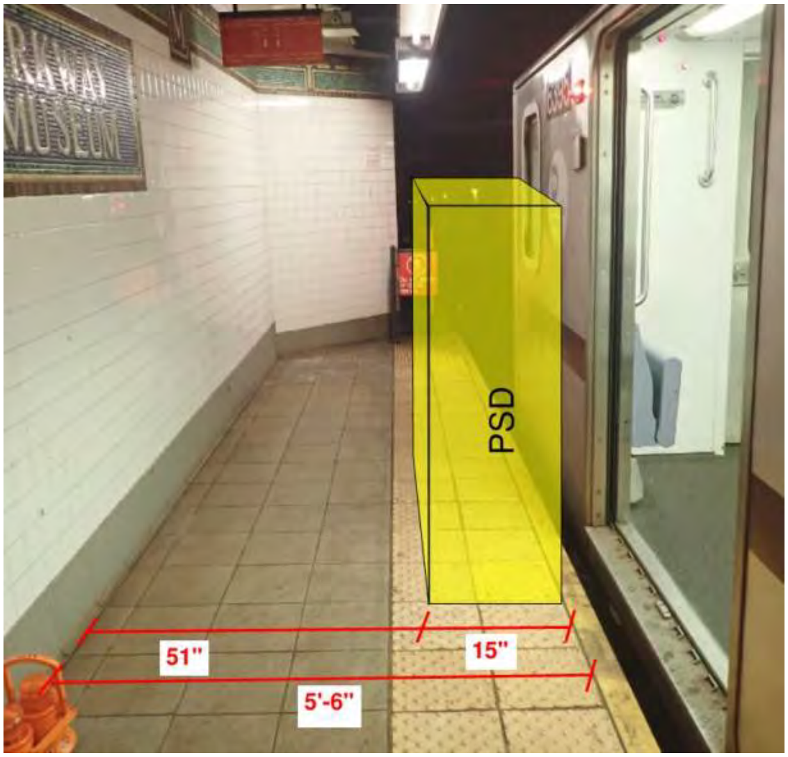

***Figure 1** – Non-Compliant egress condition*
Eastern Parkway Station

1.06 – MR 342 | Franklin Avenue Station

Summary: *Franklin Avenue Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Franklin Avenue Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Franklin Avenue Station

1.07 – MR 343 | Nostrand Avenue / Eastern Pkwy

Summary: *Nostrand Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Nostrand Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

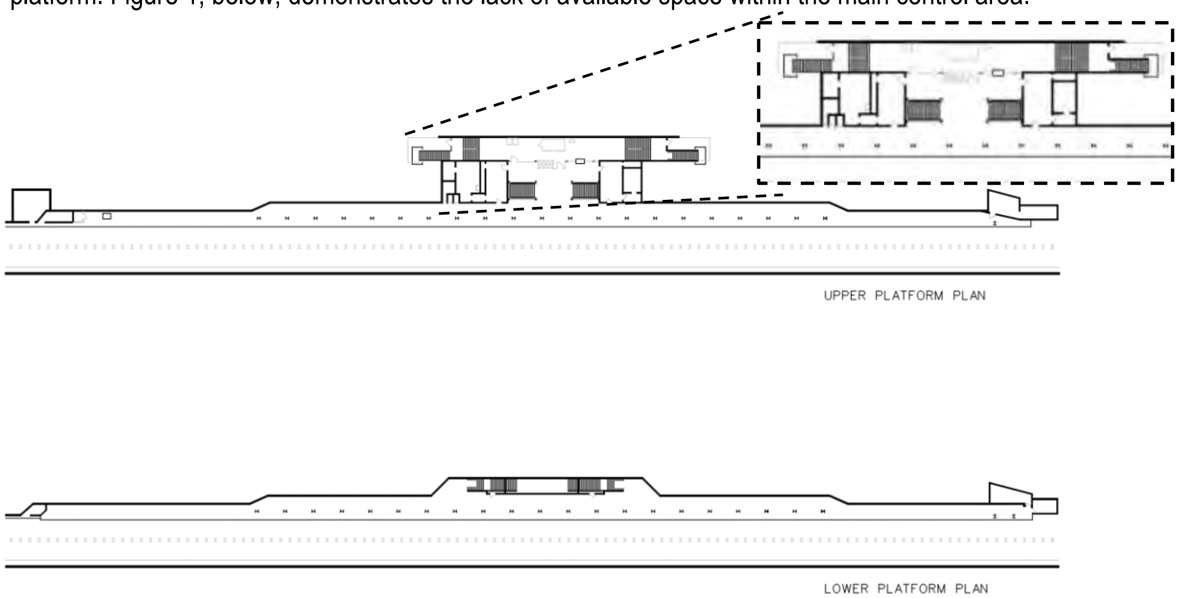

Figure 1 *– Congested/Narrow Station Plan*
Nostrand Avenue Eastern Pkwy

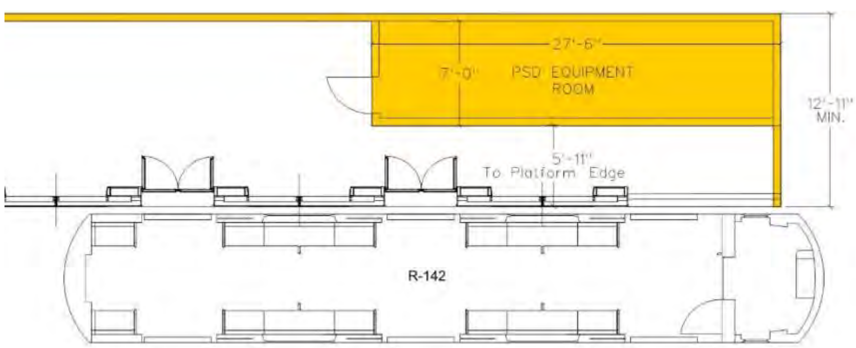

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.08 – MR 344 | Kingston Avenue

Summary: *Kingston Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Kingston Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

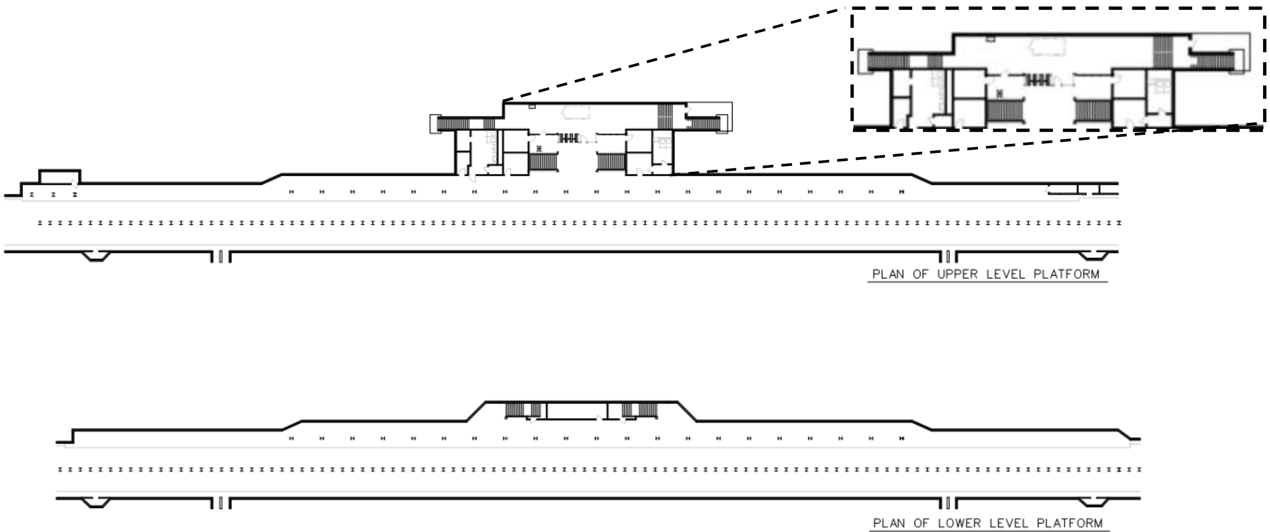

Figure 1 *– Congested/Narrow Station Plan*
Kingston Avenue

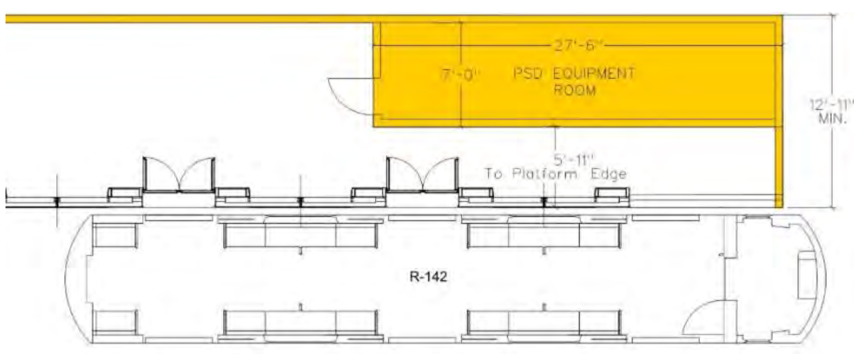

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.09 – MR 345 | Crown Heights / Utica Avenue

Summary: *Crown Heights Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Crown Heights Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge. This dimension does not allow for installation and maintenance of the 15"-wide APG/PSD system. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
Crown Heights Utica Avenue

1.10 – MR 346 | Sutter Avenue

Summary: *Sutter Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Sutter Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 8'-10" to 9'-10". The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
Sutter Avenue Station

***Figure 2** – Precast Slab*

1.11 – MR 347 | Saratoga Avenue / Livonia Avenue

Summary: Saratoga Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).

Description

The Saratoga Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 9'-10" throughout. The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

1.16 – MR 352 | New Lots Avenue Station

Summary: *New Lots Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The New Lots Avenue Station is an elevated station with one center / island platform. The platform structure is precast concrete. The width of the platforms is approximately 15'-0" throughout. The platform is straight with one row of columns supporting the station canopy. See figure 1 for reference.

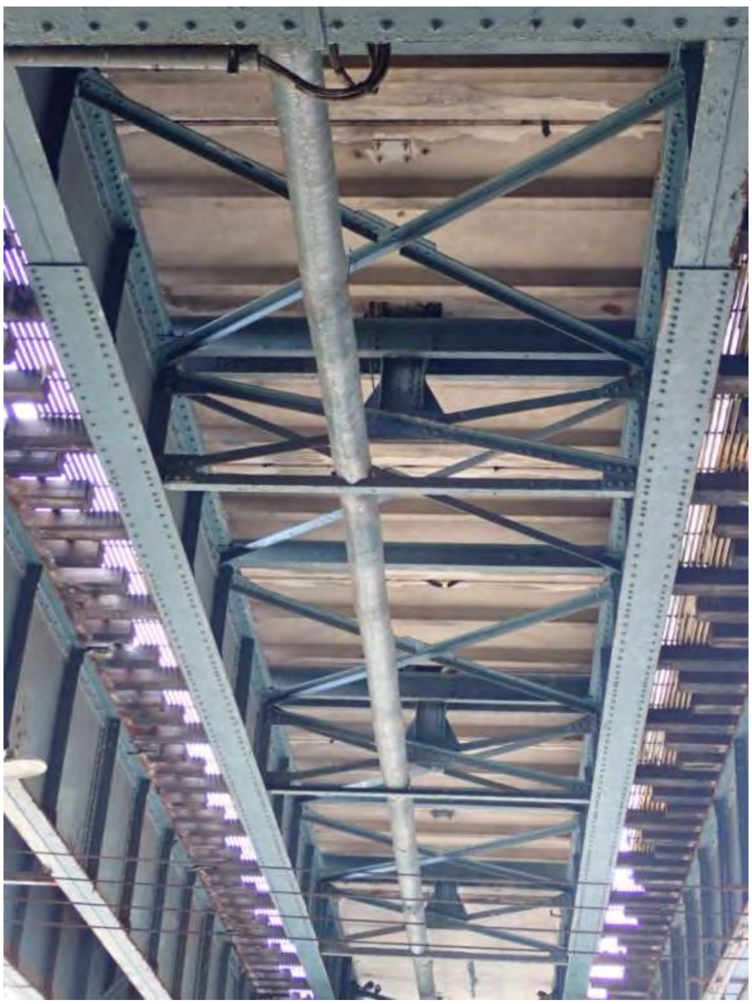

Figure 1 *– Precast Slab*
New Lots Avenue Station

1.17 – MR 378 | Woodlawn

Summary: *Woodlawn Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

Woodlawn Station is an elevated station with one center platform. The platform structure is precast concrete. The width of the platforms is approximately 9'-10" throughout. The platform is straight with one row of columns centered to support the roof. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Woodlawn Station

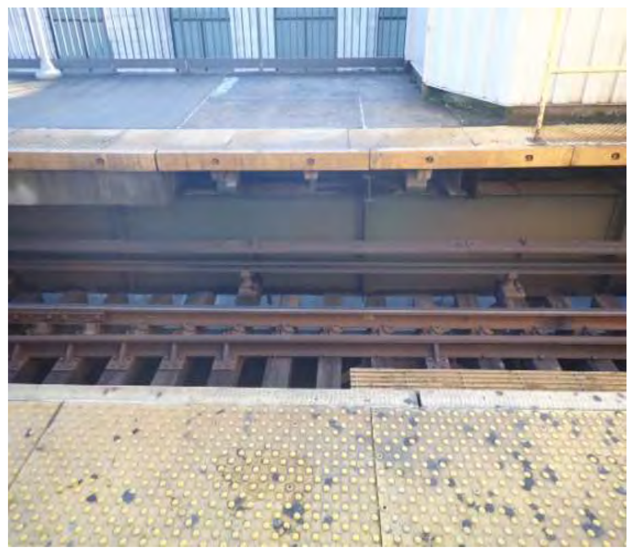

Figure 2 *– Precast Slab*

1.18 – MR 379 | Mosholu Parkway

Summary: *Mosholu Parkway Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Mosholu Parkway Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 14'-10" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

1.19 – MR 380 | Bedford Park Boulevard – Lehman College

Summary: *Bedford Park Boulevard Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Bedford Park Boulevard Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 12'-0" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

1.21 – MR 382 | Fordham Road

Summary: *Fordham Road Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Fordham Road Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-10" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

1.23 – MR 384 | Burnside Avenue

Summary: *Burnside Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Burnside Avenue Station is an elevated station with two center / island platforms. The platform structures are precast concrete. The width of the platforms is approximately 15'-4" throughout. The platforms are straight with one row of columns centered to support the roof. See figure 1 & 2 for reference.

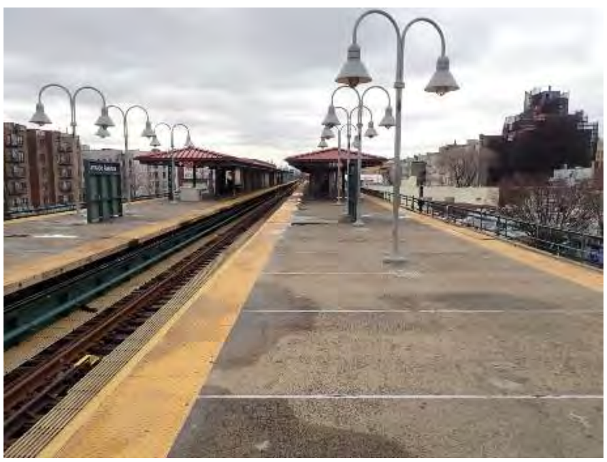

Figure 1 *– General Station Condition*
Burnside Avenue Station

Figure 2 *– Precast Slab*
Burnside Avenue Station

1.24 – MR 385 | 176th Street

Summary: *176th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The 176th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-8" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

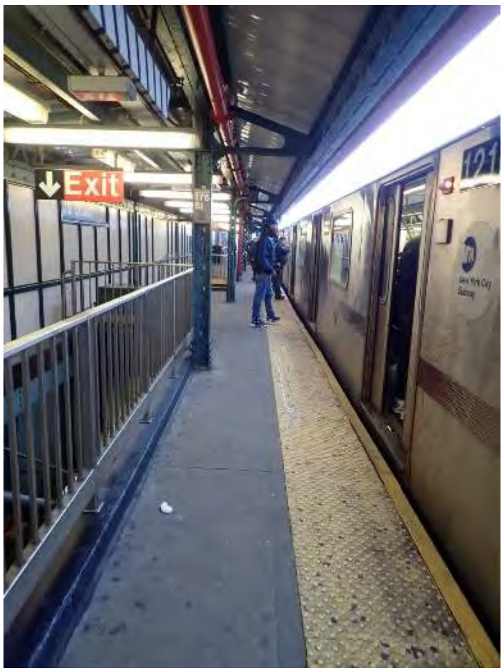

***Figure 1** – General Station Condition*

176th Street Station

1.25 – MR 386 | Mt. Eden Avenue

Summary: *Mt. Eden Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Mt. Eden Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 12'-0" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Mt. Eden Avenue Station

Figure 2 *– Precast Slab*
Mt. Eden Avenue Station

1.26 – MR 387 | 170th Street

Summary: *170th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The 170th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 12'-0" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
170th Street Station

Figure 2 *– Precast Slab*
170th Street Station

1.27 – MR 388 | 167th Street

***Summary:** 167th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The 167th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 12'-2" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
167th Street Station

***Figure 2** – Precast Slab*
167th Street Station

1.28 – MR 389 | 161st Street Yankee Stadium

Summary: *161st Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The 161st Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms is approximately 11'-6" throughout. The platforms are straight with one row of columns inset in the windscreen and another set adjacent to the platform edge. See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
161st Street Station

***Figure 2** – Precast Slab*
161st Street Station

1.29 – MR 390 | 149th Street Grand Concourse

Summary: *The 149th Street Grand Concourse Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the northbound platform as the existing width is 4'-6" (see figure 1).*

Description

The 149th Street Grand Concourse Upper Level Station is a below-grade station with two straight center/island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-6' to 19'-6".

The platform width at the southbound end of the northbound platform is 4'-6" or 54". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

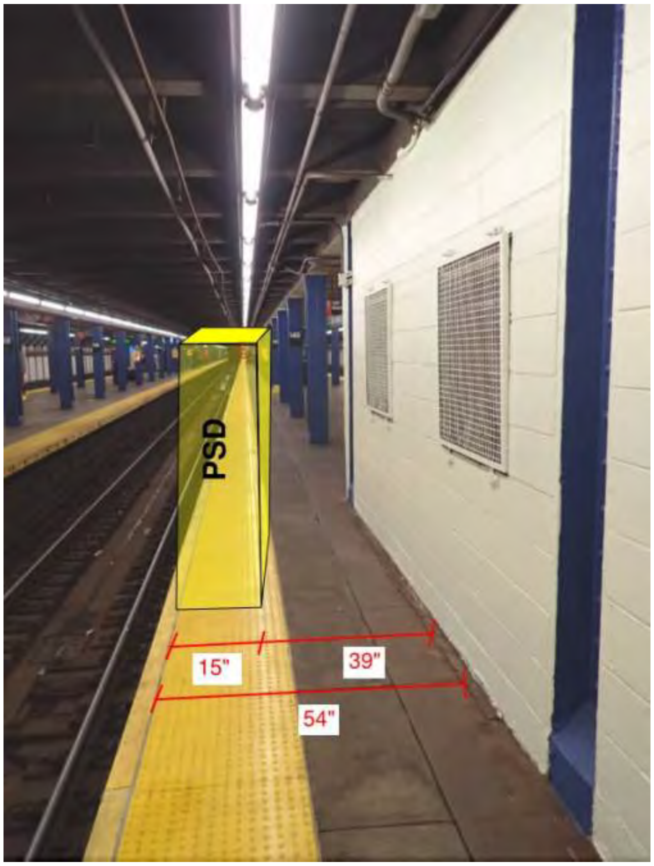

***Figure 1** – Non-Compliant egress condition*
149th Street Grand Concourse Station

1.30 – MR 391 | 138th Street Grand Concourse

Summary: *138th Street Grand Concourse Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 138th Street Grand Concourse Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-6". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
138th Street Grand Concourse Station

1.31 – MR 392 | 125th Street

Summary: *125th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

125th Street Station is a below-grade station with two levels of straight center / island platforms. The no. 4 train utilizes both the upper and lower level. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 29'-8". At the lower platform, the implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The upper platform is infeasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 2 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

1.32 – MR 393 | 116th Street

Summary: *116th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

116th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-8" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

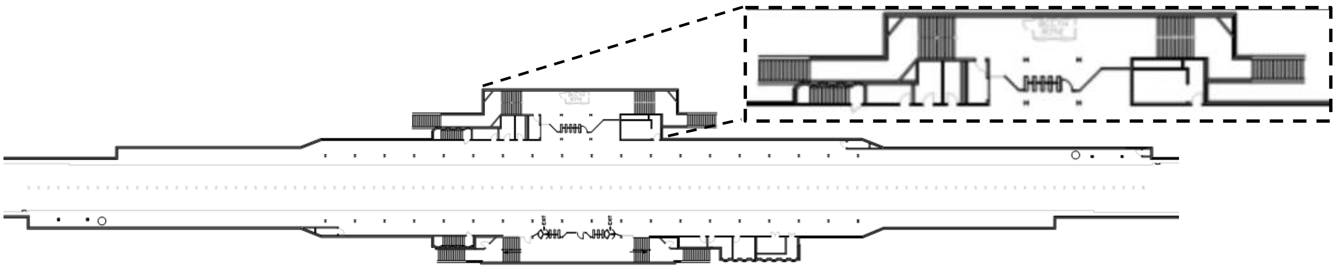

***Figure 1** – Congested/Narrow Station Plan*
116th Street Station

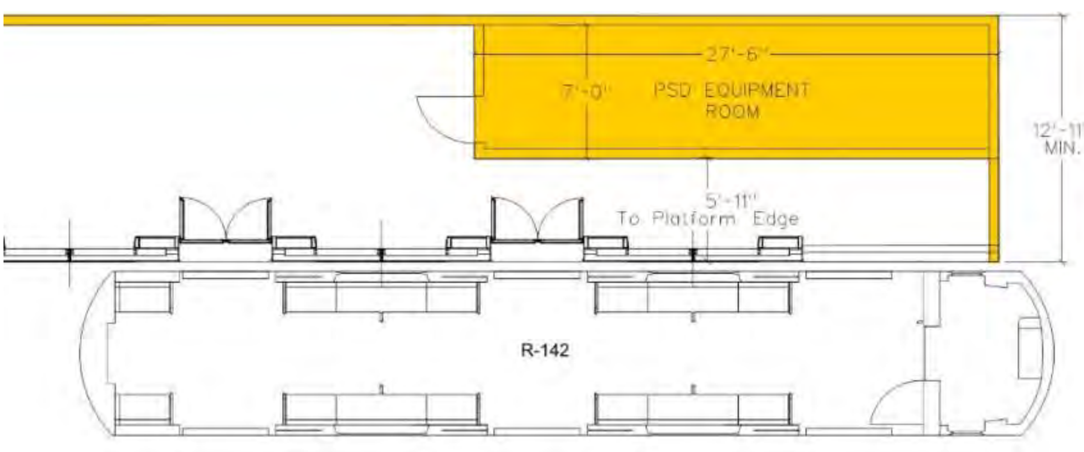

***Figure 2** – Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.33 – MR 394 | 110th Street

Summary: *110th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

110th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-8" to 8'-0". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

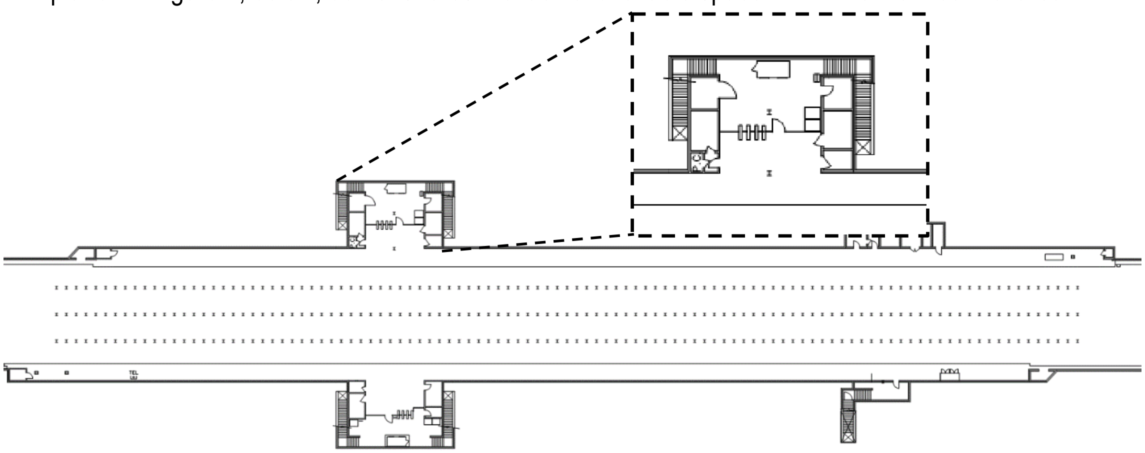

***Figure 1** – Congested/Narrow Station Plan*
110th Street Station

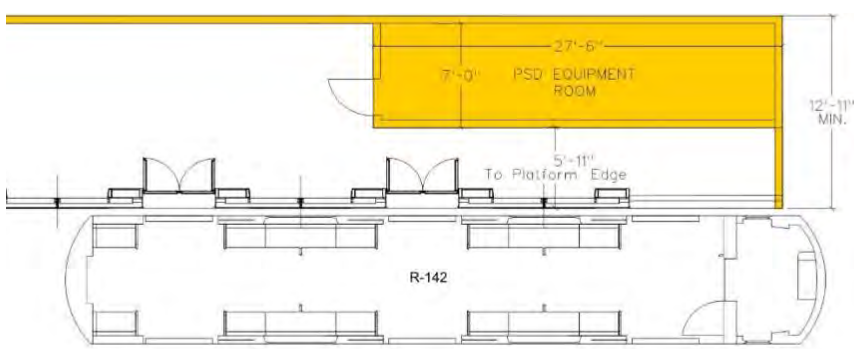

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.34 – MR 395 | 103rd Street

Summary: *103rd Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

103rd Street Station is a below ground station with two side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. There are no columns located throughout the platforms. The platform widths are approximately 7-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the mezzanine control area of the station (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

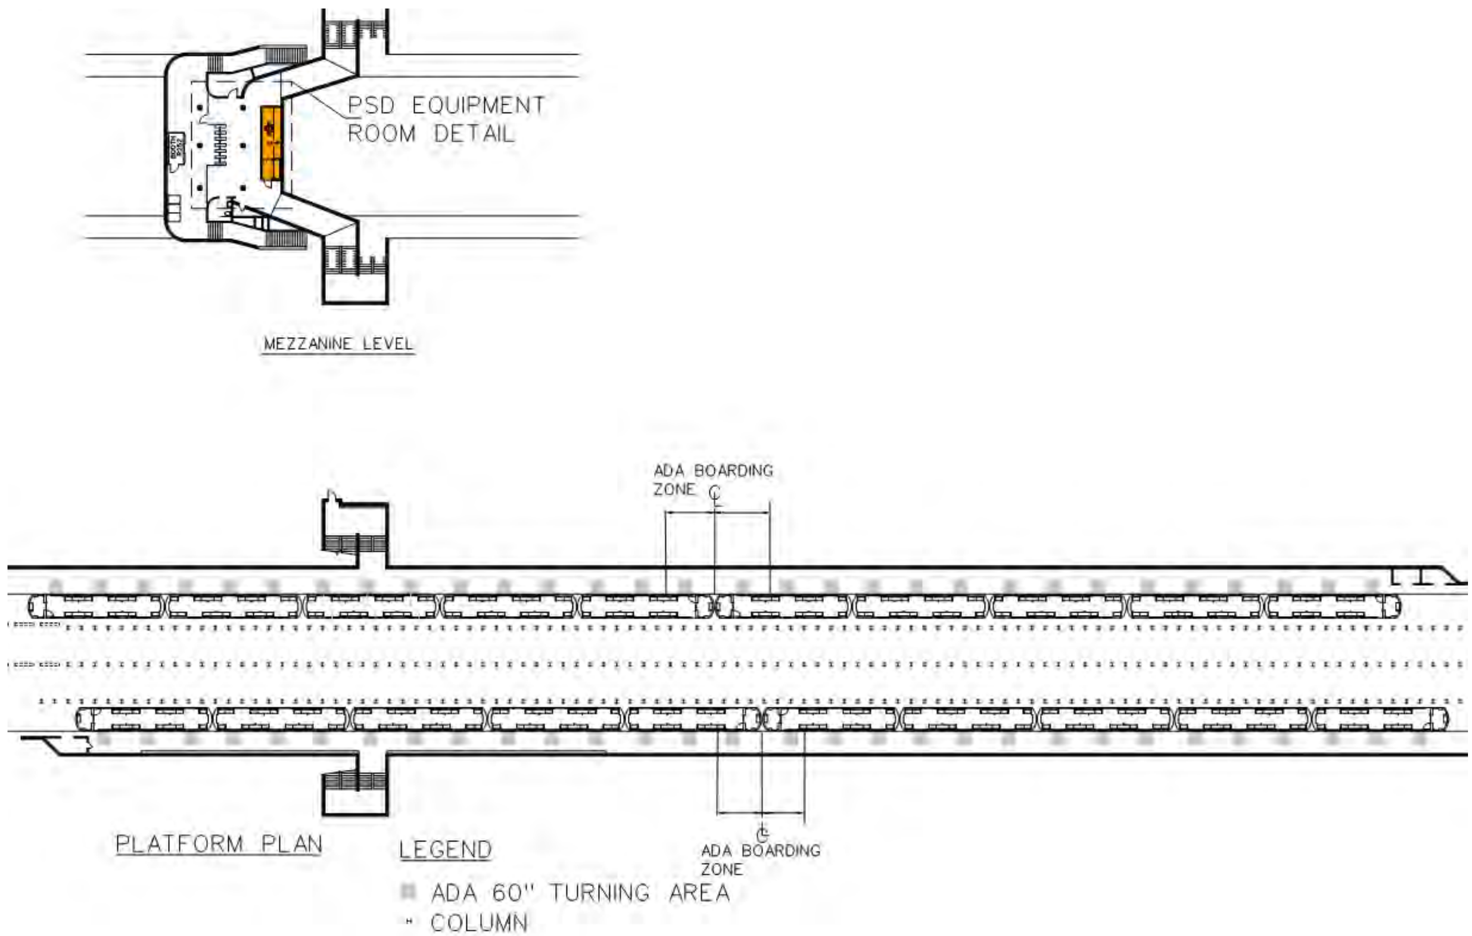

Figure 1 *– Overall Station Plan*
103rd Street Station

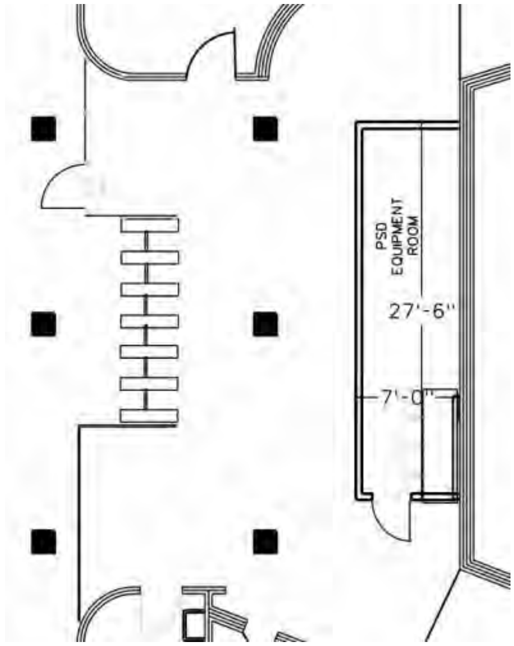

Figure 2 *– PSD Equipment Room 1 Detail*
103rd Street Station

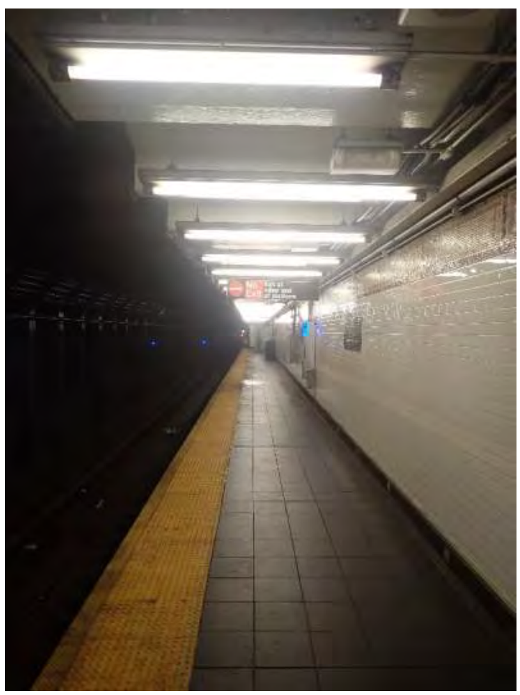

Figure 3 *– Typical platform view*
103rd Street Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal service)

Station Name	103rd Street
Peak Demand Load from ConEd Report, (kW)	26.8
Apparent Power (kVA)	33.5
Station Peak Demand Load, Max Current, (A)	93.1
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	251.2
Station Service Power Capacity, (Main SB or SG Rating), (A)	400.0
Service Spare Capacity, (A)	148.9
Is Electrical Service Adequate?	**Yes**
Notes	Service rating of 400A is based on field observations. Station has only (1) meter readings for Normal service. The station Reserve meter was NOT accessible during field survey. (No meter in Reserve EDR) 1 Line diagram provided is not current.

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $34.5M to install PSDs (See Appendix E)

1.35 – MR 396 | 96th Street

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 5'-0" (see figure 1).*

Description

96th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 12'-10".

The platform width at the end of the southbound platform is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

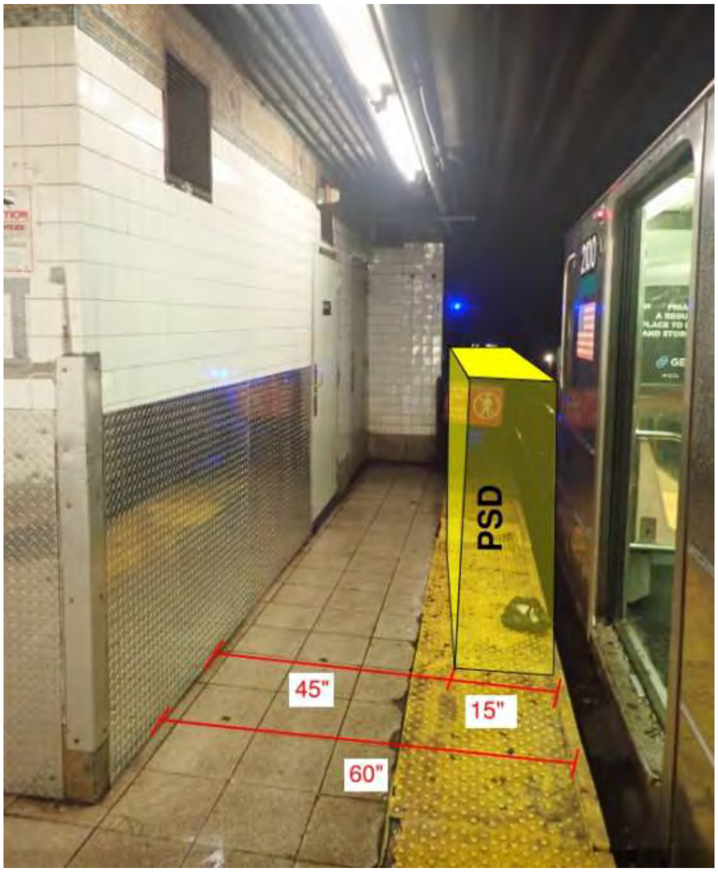

Figure 1 *– Non-Compliant egress condition*
96th Street Station

1.36 – MR 397 | 86th Street

Summary: *86th Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the center stairs as the remaining width would be 31" (see figure 1).*

Description

The 86th Street Station is a below-grade station consisting of two side platforms on two levels. The No. 4 service normally runs at the lower level, with night service on the upper level. At the upper level, the platforms are approximately 13'-8" wide. The platforms are straight with one rows of columns at 46" from the edge of the platform. The implementation of a platform edge barrier would reduce this width to 31" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The 86th Street lower level is infeasible due to lack of space for a PSD equipment room. The introduction of an equipment room on the lower platform would create 24" pinch points at the columns which do not comply with the minimum 32" required by ADA.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA dimension*
86th Street Station

1.37 – MR 398 | 77th Street

Summary: *77th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 77th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-8". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
77th Street Station

1.38 – MR 399 | 68th Street Hunter College

__Summary:__ 68th Street Hunter College Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of both platforms as the existing width is 4'-2" (see figure 1).

Description

68th Street Hunter College Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-2' to 11'-10".

Platform width at the southbound end of the northbound & southbound platform is 4'-2" or 50". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

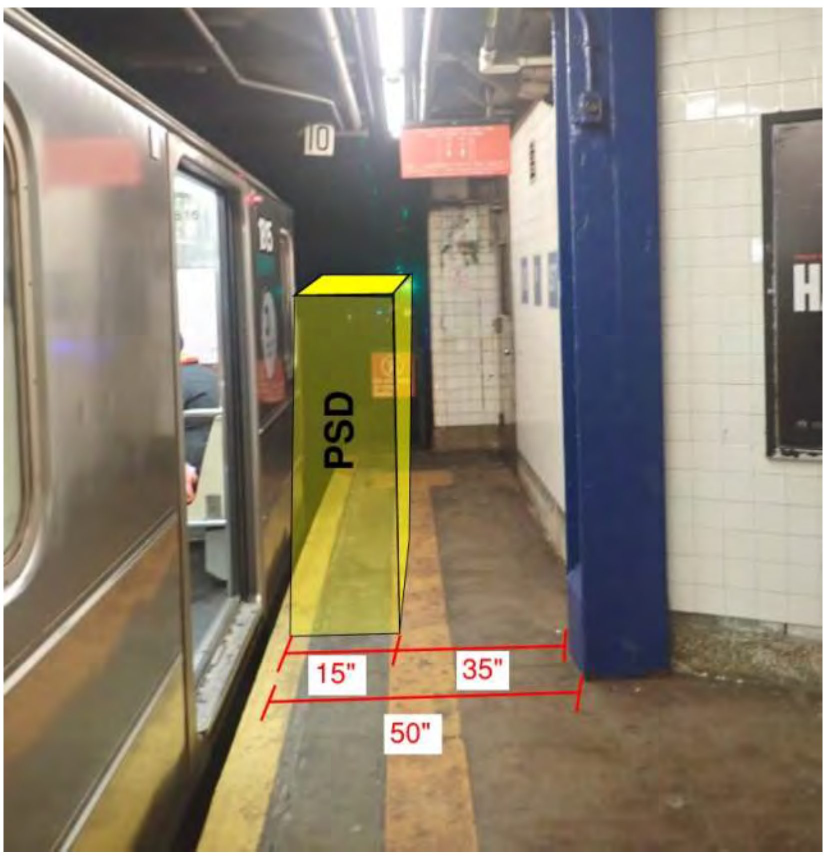

***Figure 1** – Non-Compliant egress condition*
68th Street Hunter College Station

1.39 – MR 400 | 59th Street

Summary: *59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 59th Street Station is a below-grade station with two levels of two straight side platforms. The No. 4 service runs normally on the lower platform, with night service on the upper platform. The upper level platform will be the subject of a future report for the No. 6 line. The platform structures are cast-in-place concrete. The width of the lower level platforms ranges from 3'-4' to 13'-0". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of a 32" pinch point. The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

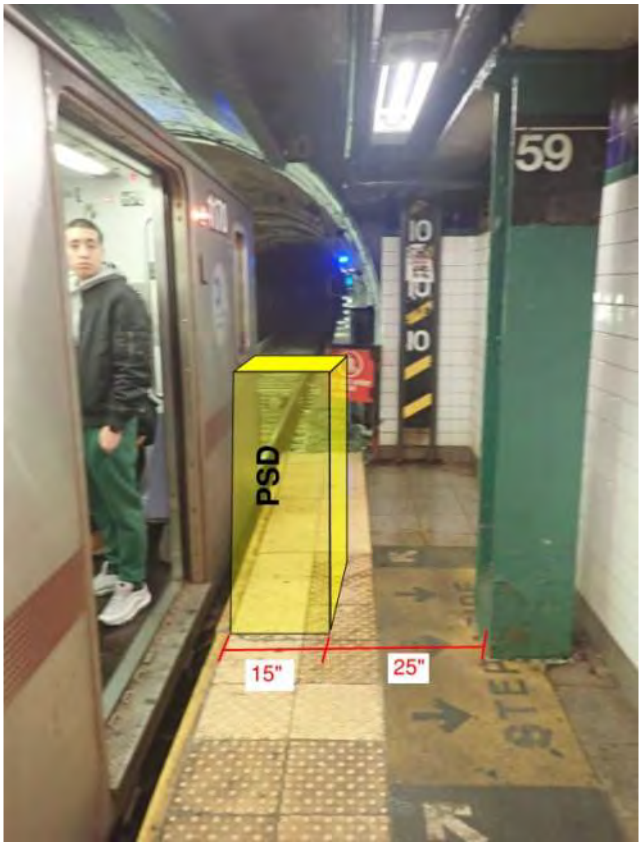

Figure 1 *– Non-Compliant egress condition*
59th Street Station- lower level

1.40 – MR 401 | 51st Street

Summary: *51st Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

51st Street Station is a below-grade station with two side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edge. Column faces measure approximately 3'-8" from the platform edge. The platform widths are approximately 11-4" to 20'-0". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the northbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

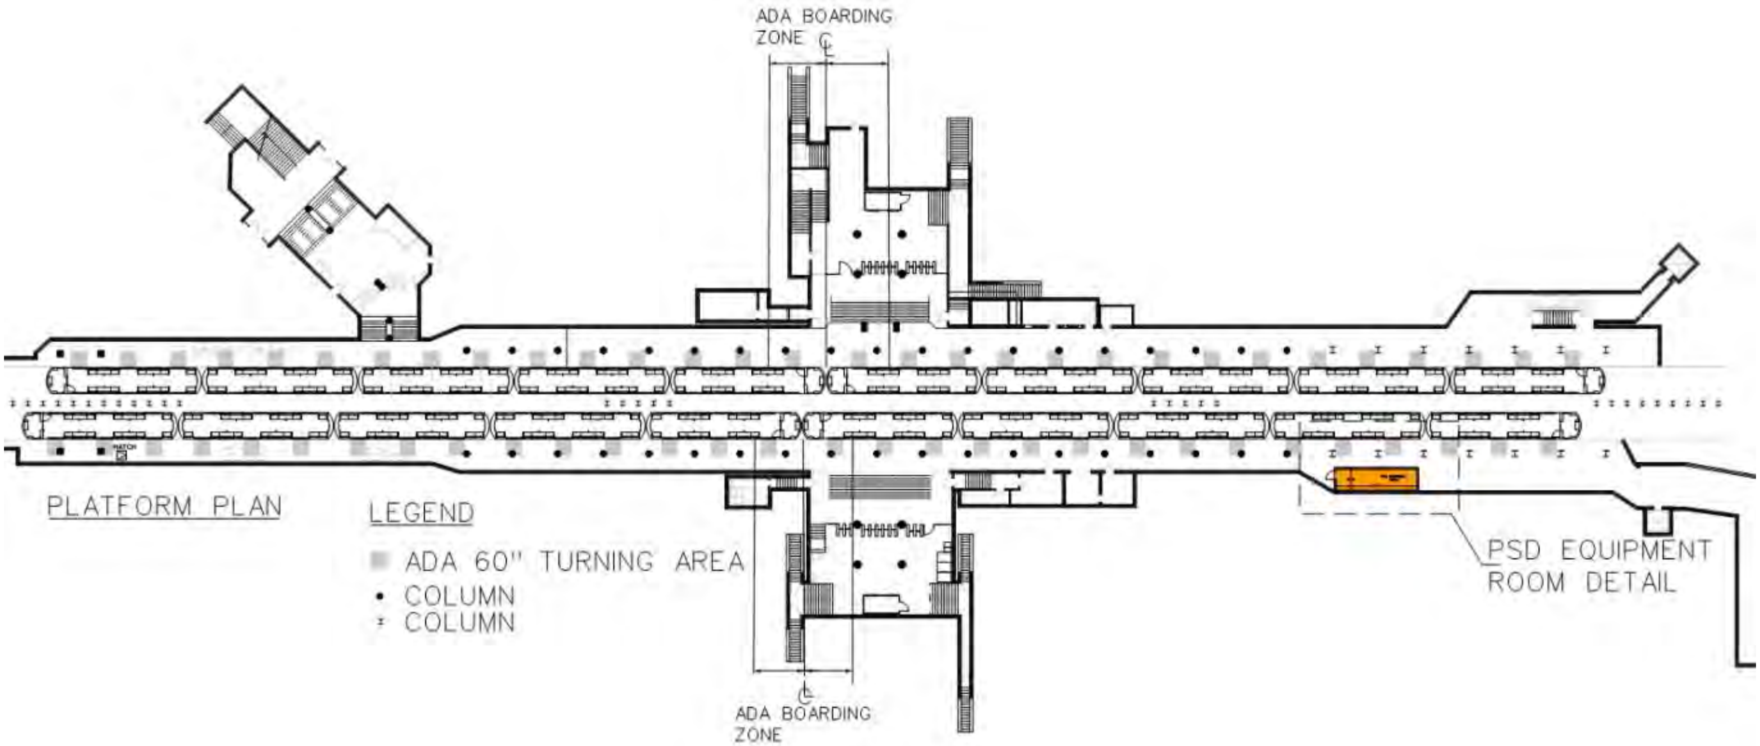

Figure 1 *– Overall Station Plan*
51st Street Station

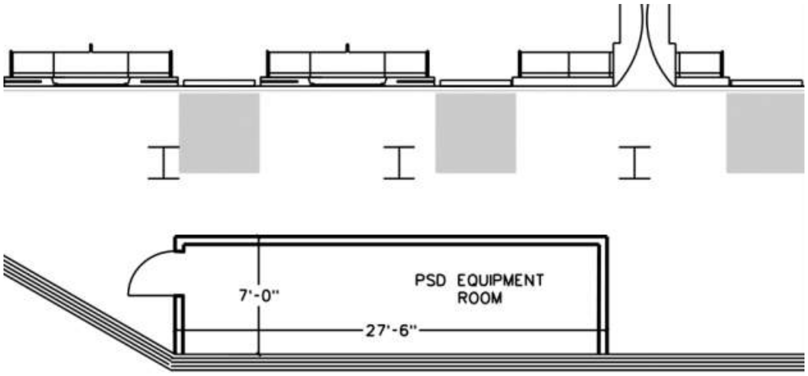

***Figure 2** – PSD Equipment Room 1 Detail*
51st Street Station

***Figure 3** – Typical platform view*
51st Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service)

Station Name	51st Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	28.8
Apparent Power (kVA)	36.0
Station Peak Demand Load, Max Current, (A)	100.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	258.1
Station Service Power Capacity, (Main SB or SG Rating), (A)	600
Service Spare Capacity, (A)	342
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 600 A Service switch. Station has (2) separate meter readings for each Normal & Reserve service. 1 Line diagram provided is not current.

***Table 1**. Normal Service Power Capacity Analysis*

Station
Power Capacity Analysis (Reserve Service)

Station Name	51st Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	55.0
Apparent Power (kVA)	68.8
Station Peak Demand Load, Max Current, (A)	191.0
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	349
Station Service Power Capacity, (Main SB or SG Rating), (A)	700
Service Spare Capacity, (A)	351
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram having 700A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service.

Table 2. Reserve Service Power Capacity Analysis

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.3M to install APGs and $34.4M to install PSDs (See Appendix E)

1.41 – MR 402 | 42nd Street Grand Central

Summary: *42nd Street Grand Central Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 42nd Street Grand Central Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-10' to 24'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

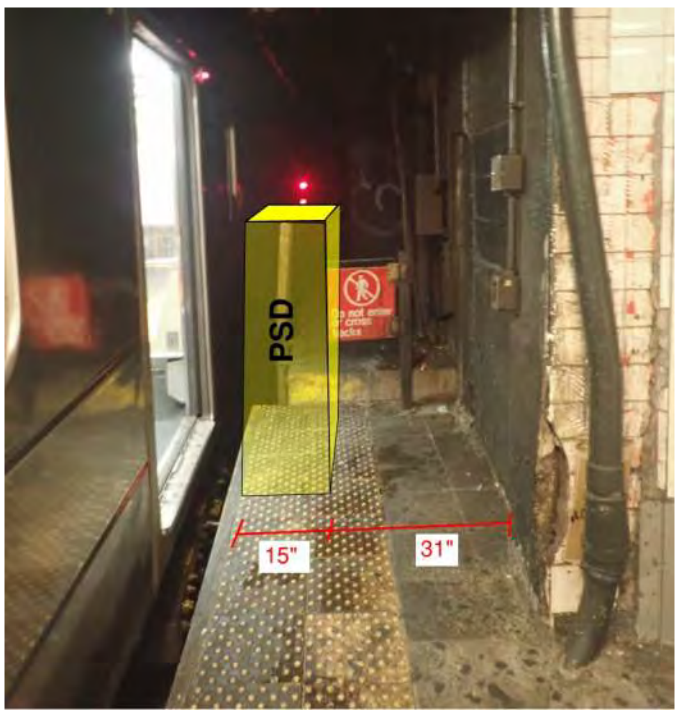

Figure 1 *– Non-compliant ADA condition*
42nd Street Grand Central Station

1.42 – MR 403 | 33rd Street

Summary: *33rd Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

33rd Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
33rd Street Station

1.43 – MR 404 | 28th Street

Summary: *28th Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

28th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 14" from the platform edge. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 14" from the edge*
28th Street Station

1.44 – MR 405 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

23rd Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 14" from the platform edge. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 14" from the edge*
23rd Street Station

1.45 – MR 406 | 14th Street Union Square

Summary: *14th Union Square Station is not feasible for both APGs and PSDs due to the presence of platform edge gap fillers located at all southbound platform edges. The existing gap fillers are a dynamic assembly that extends the platform edge when a train arrives, and recedes when the train departs. This moving assembly prevents the installation of a static PSD system. Please see figure 1 for reference.*

Description:

Due to the sharp curvature of the platforms at 14th Street Union Square, platform edge gap fillers are necessary to bridge the gap between the current rolling stock's doors and the platform edge.

Figure 1 *–Platform Edge Gap Fillers*
14th Street Union Square Station

1.46 – MR 407 | Astor Place 4th Avenue

Summary: *Astor Place Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 15" (see figure 1).*

Description

The Astor Place Station is a below-grade station with two curved side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 2'-6' to 10'-8". The implementation of a platform edge barrier would reduce this lesser width below the required minimum of 32". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.=

Figure 1 *– Non-compliant ADA condition*
Astor Place Station

1.47 – MR 408 | Bleeker St.

Summary: *Bleeker St. Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Bleeker Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
Bleeker St. Broadway Lafayette Station

1.48 – MR 409 | Spring St.

Summary: *Spring St. Station is not feasible for both APGs and PSDs as the columns which are located 22" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Spring St. Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 22" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 22" from the edge*
Spring St. Station

1.49 – MR 410 | Canal Street

Summary: *Canal Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Canal Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Canal Street Station

1.50 – MR 411 | Brooklyn Bridge City Hall

Summary: *Brooklyn Bridge City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the center stairs as the remaining width would be 17" (see figure 1).*

Description

The Brooklyn Bridge City Hall Station is a below-grade station consisting of two center / island platforms. The platforms are approximately 15'-6" to 21'-2" wide. The platforms are mildly curved with two rows of columns at 32" from the edge of the platform. The implementation of a platform edge barrier would reduce this width to 17" or less* which would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Brooklyn Bridge City Hall Station

1.51 – MR 412 | Fulton Street

Summary: *Fulton Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Fulton Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edge. Column faces measure approximately 3'-2" from the platform edge. The platform widths range from approximately 7'-6" to 19'-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the southbound platform of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for '4' Line Stations
(Fulton Street Station)

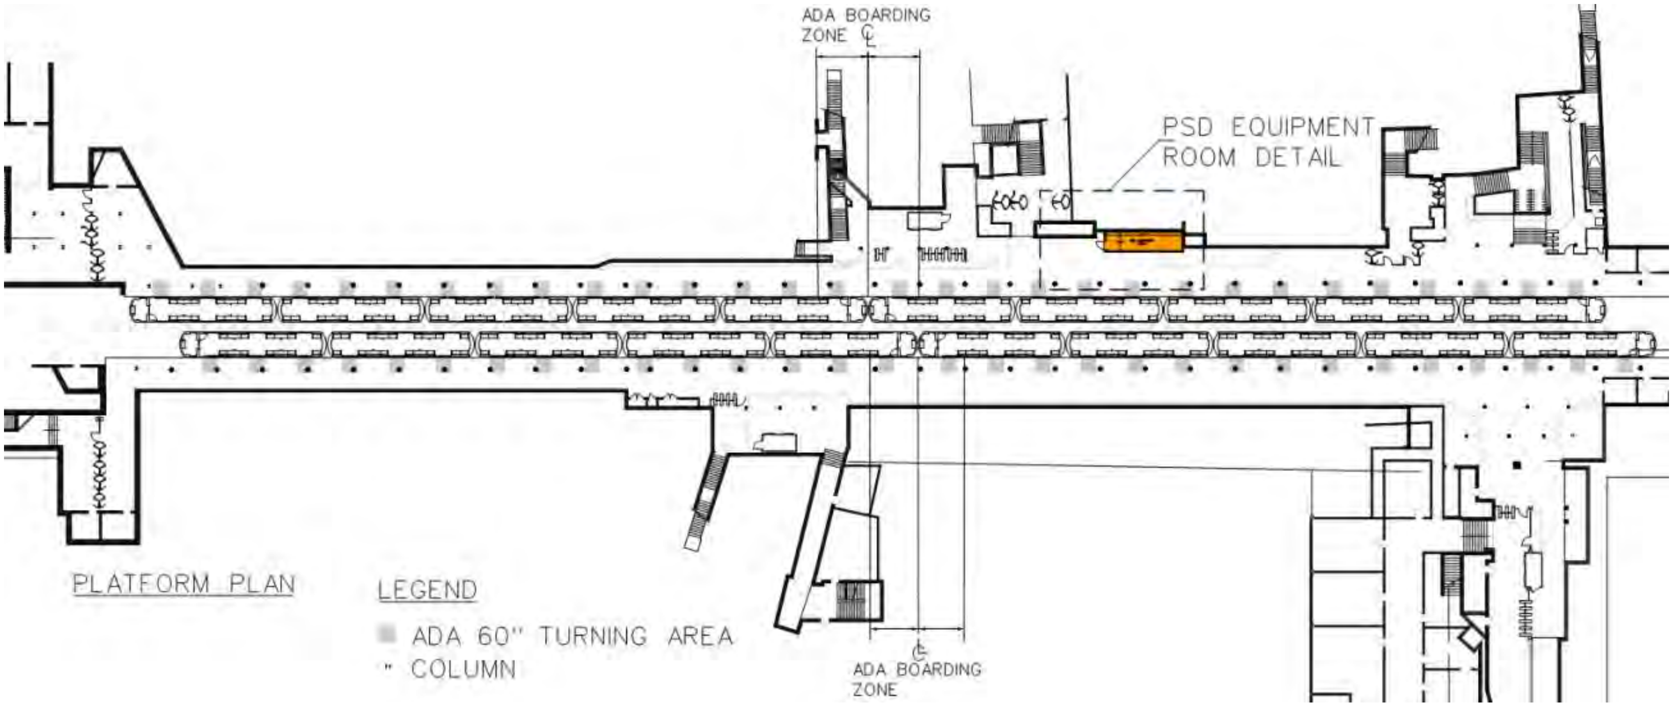

Figure 1 – Overall Station Plan

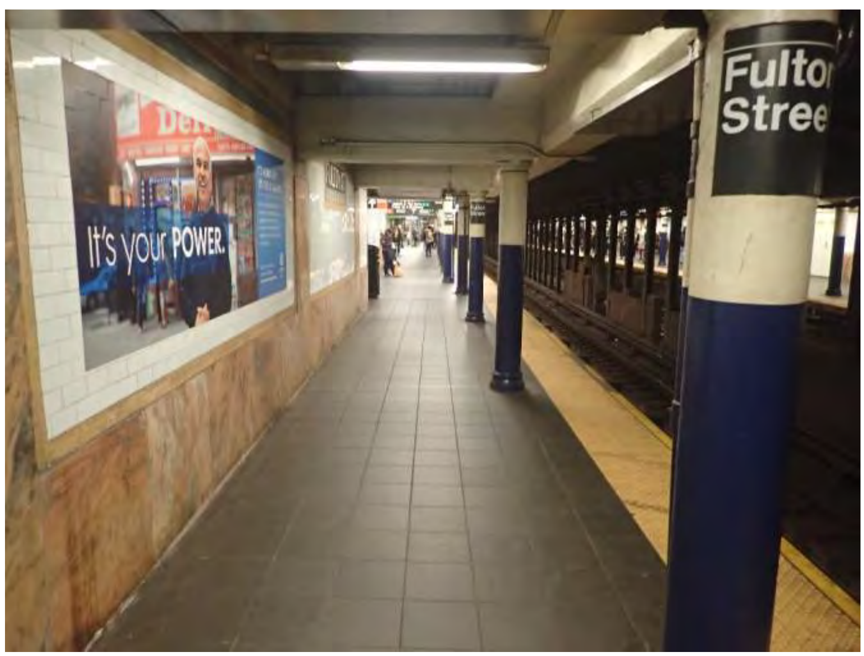

Figure 3 *– Typical platform view*
Fulton Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted both parallel and perpendicular to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Table 2*. Norma l Reserve Service Power Capacity Analysis*

Historic Restrictions:
This station is a designated historical place. As such, any capital improvement will be subject to review by the State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.5M to install APGs and $34.6M to install PSDs (See Appendix E)

1.52 – MR 413 | Wall Street

***Summary:** Wall Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Wall Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

***Figure 1 –** Column 20" from the edge*
Wall Street Station

1.53 – MR 414 | Bowling Green

Summary: *Bowling Green Station is feasible for both APGs and PSDs. Two structural columns will need to be relocated due to their proximity to the platform edge. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bowling Green Station is a below-grade station with one side platform & one center / island platform that has only one active platform edge (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edges. Column faces measure approximately 2'-2" from the platform edge. Two columns on the southbound platform measure 17" from the platform edge. The platform widths range approximately from 14-0" – 24'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the northbound platform of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are approximately tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> *a. Column location in relation to the platform edge*
> *b. Platform edge clearance adjacent to stairs and other impediments*
> *c. Impacts to ADA path of travel and boarding areas*
> *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> *e. Sufficient platform width*
> *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> *c. Confirmation of adequate power for PSD/APG/RPSDs*
> *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> *e. Determination of communications requirements, availability and cost*
> *f. Determination of gap detection and entrapment avoidance technology requirements*
> *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

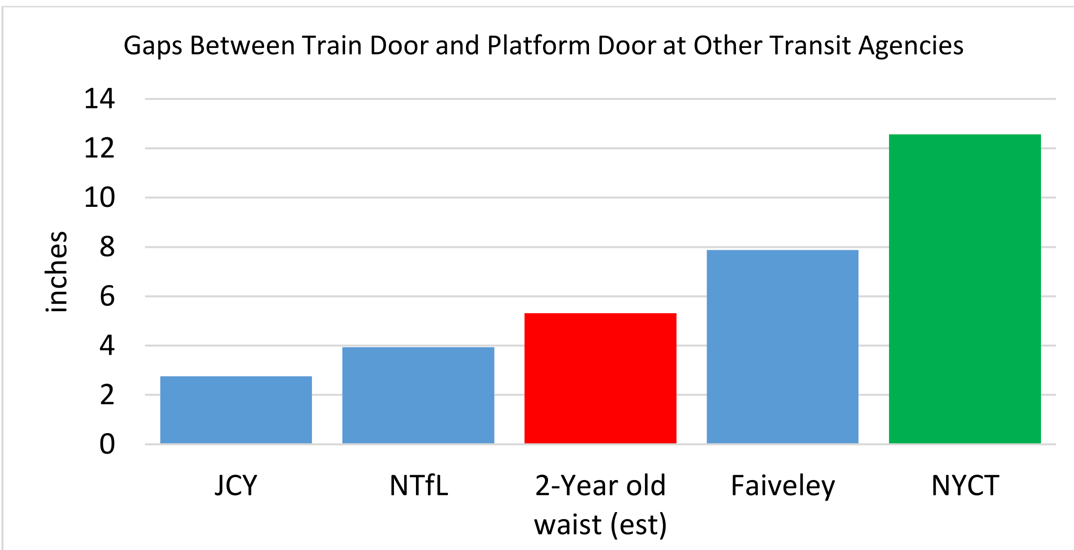

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

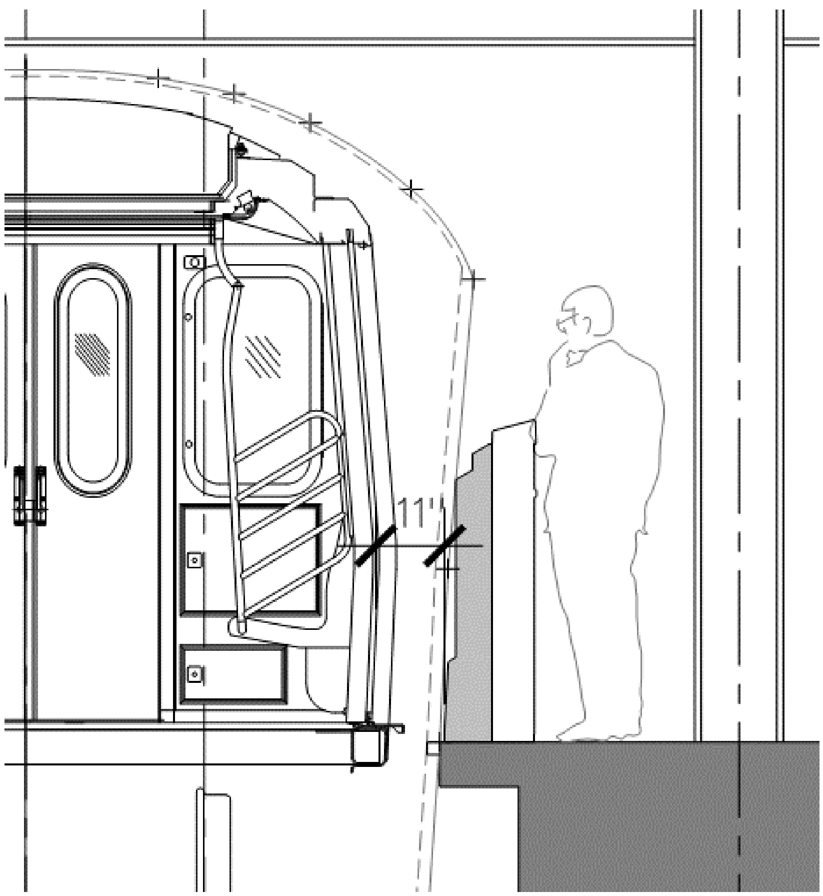

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber "bumpers" on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6" into the line equipment envelope. This would leave a 5" gap between the platform and car doors allowing approximately 2" of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **<u>bold/underline</u>**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	**3rd Ave.**	**6th Ave.**	**14 St / Union Square**	**1st Ave.**
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

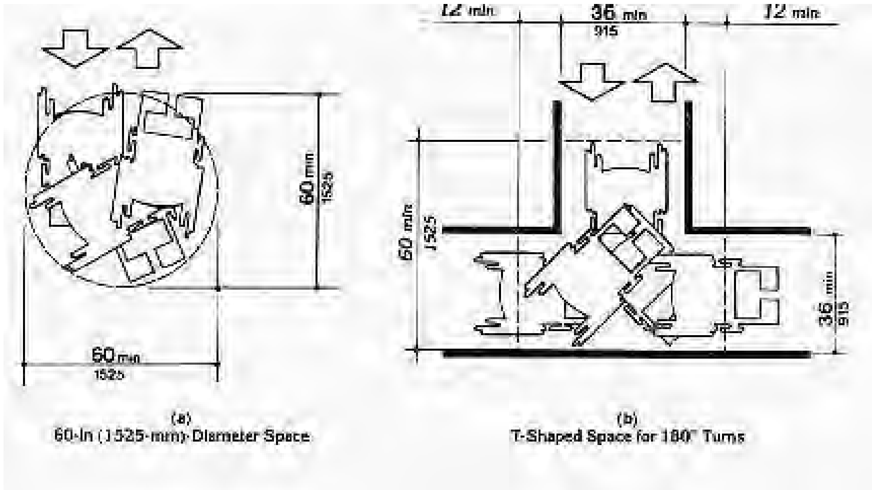
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

> *Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.*

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

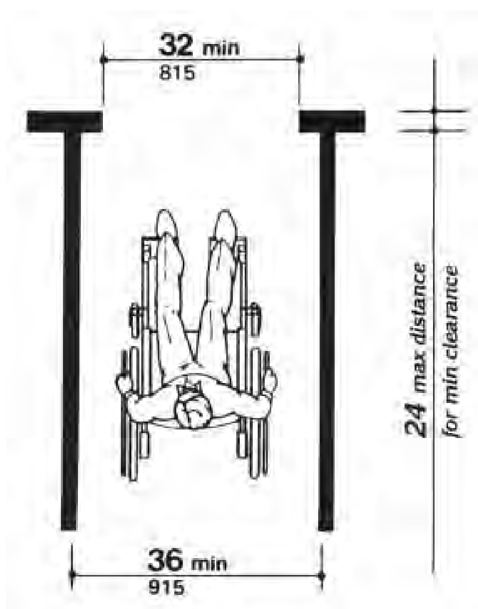


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

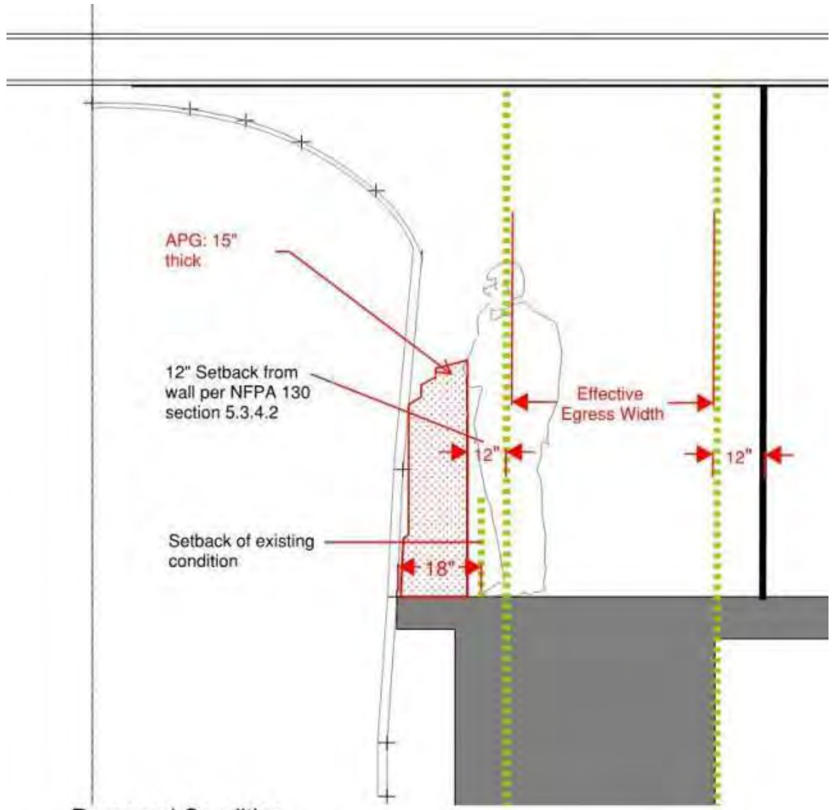
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

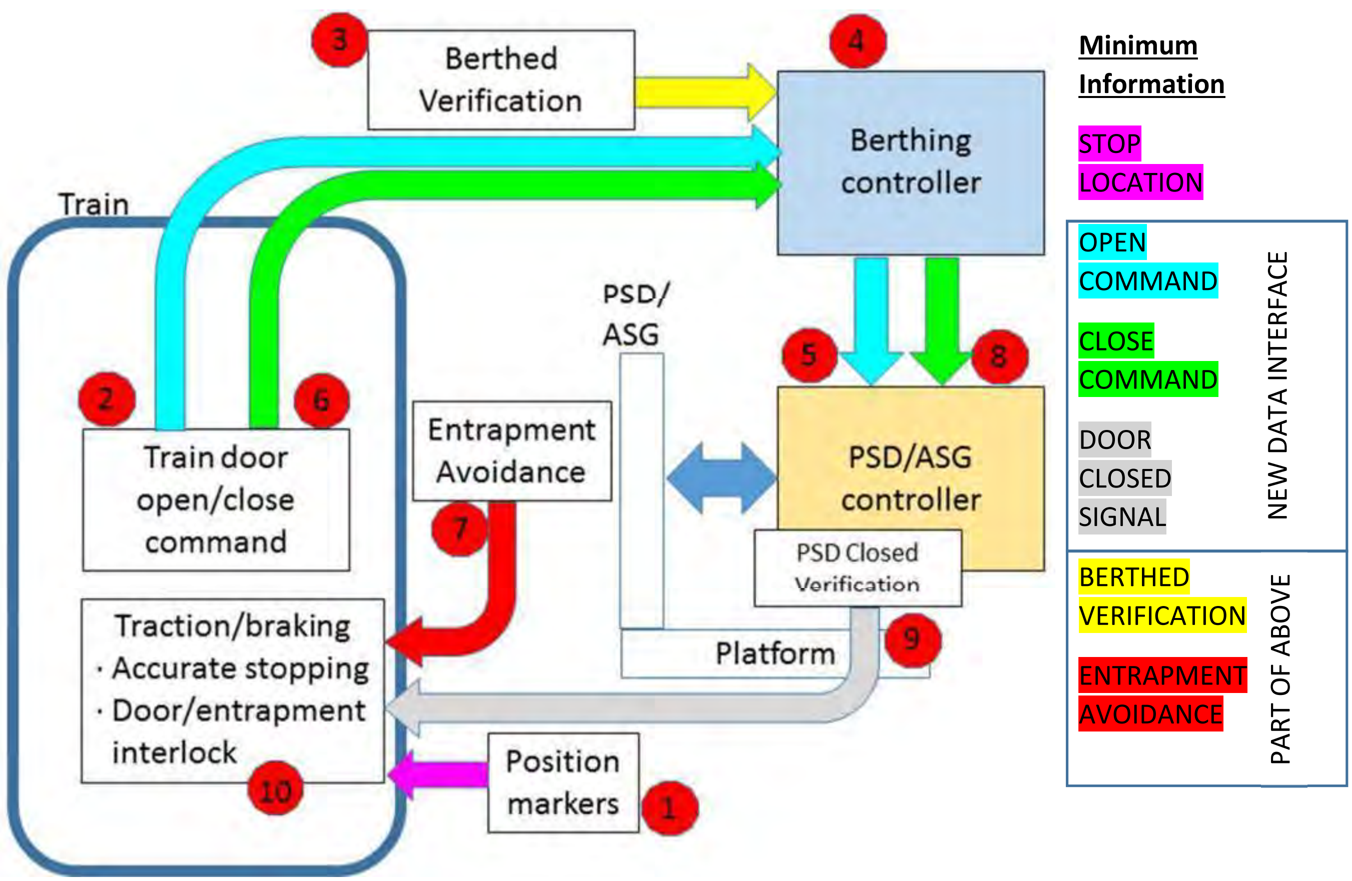
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

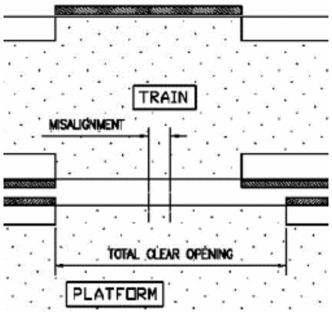
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

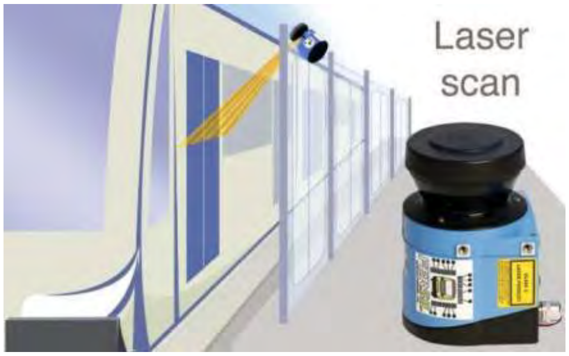
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4’-0”). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

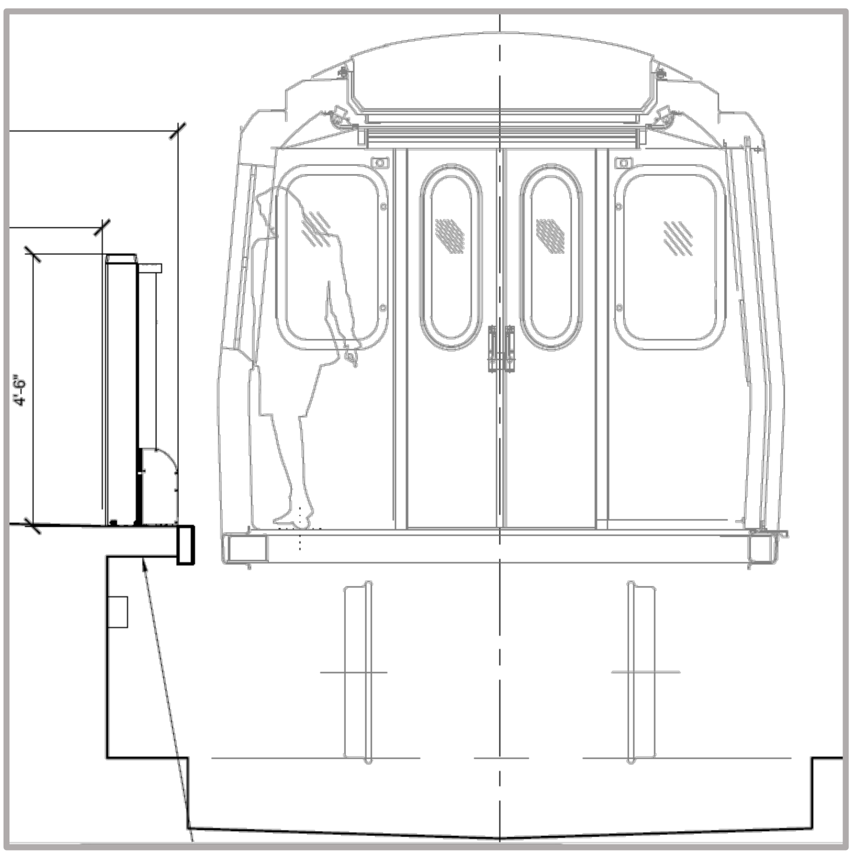


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

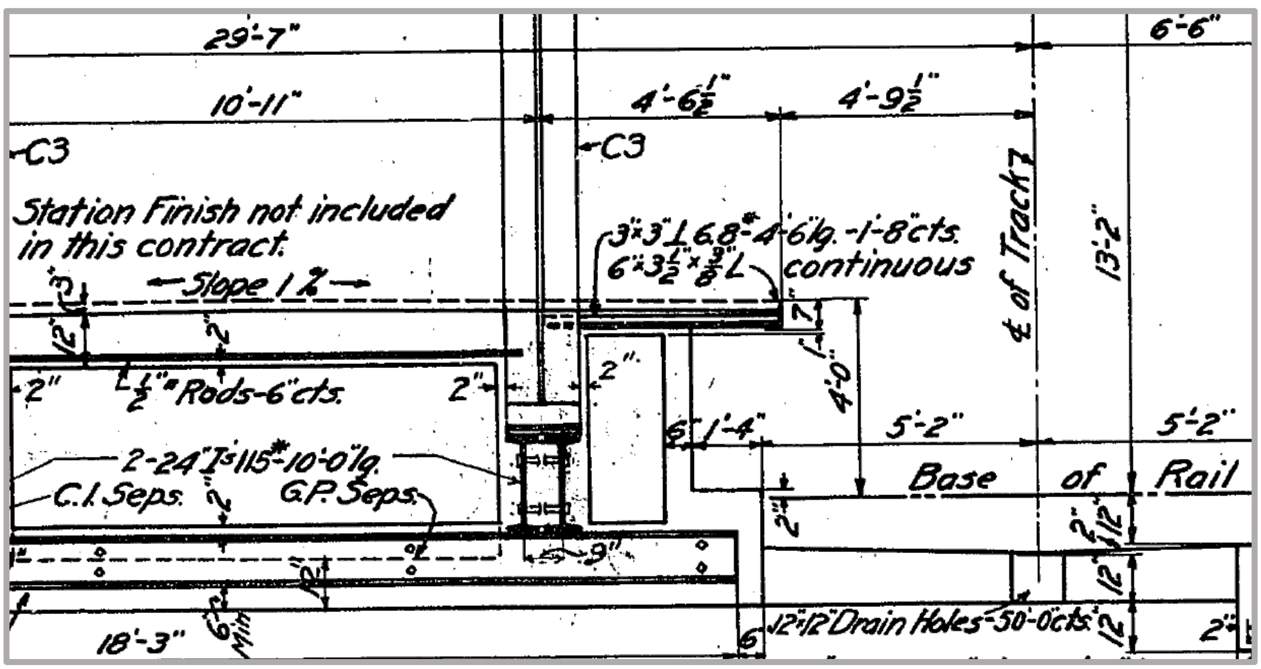

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6” thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1’-2” long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

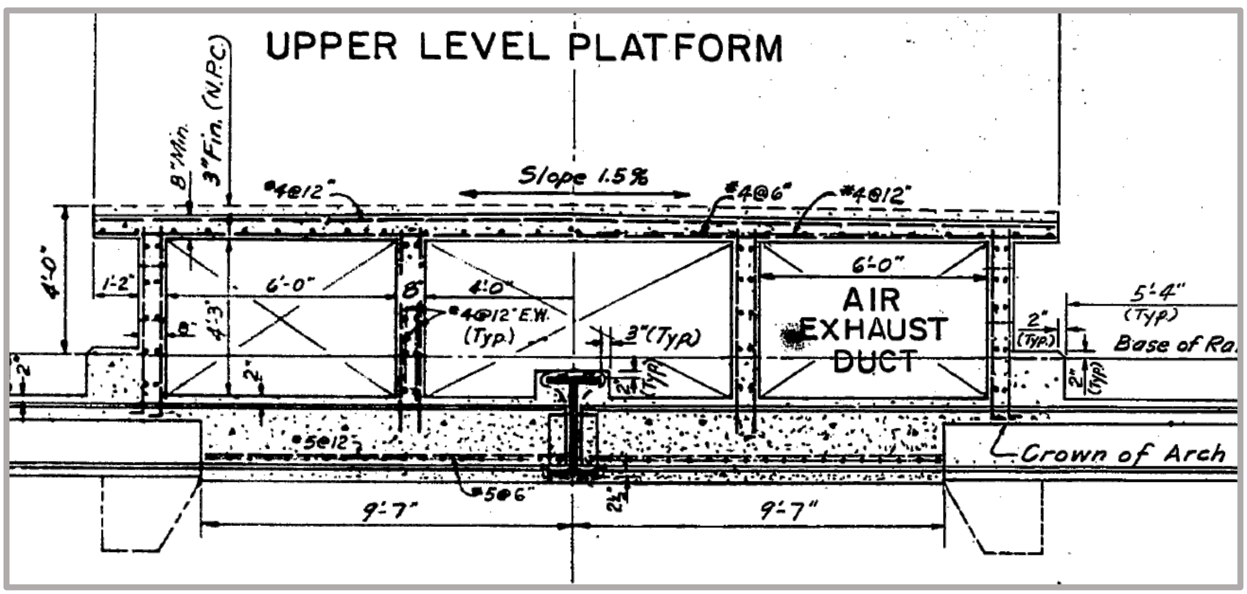

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; “E”, “J”, and “Z” trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

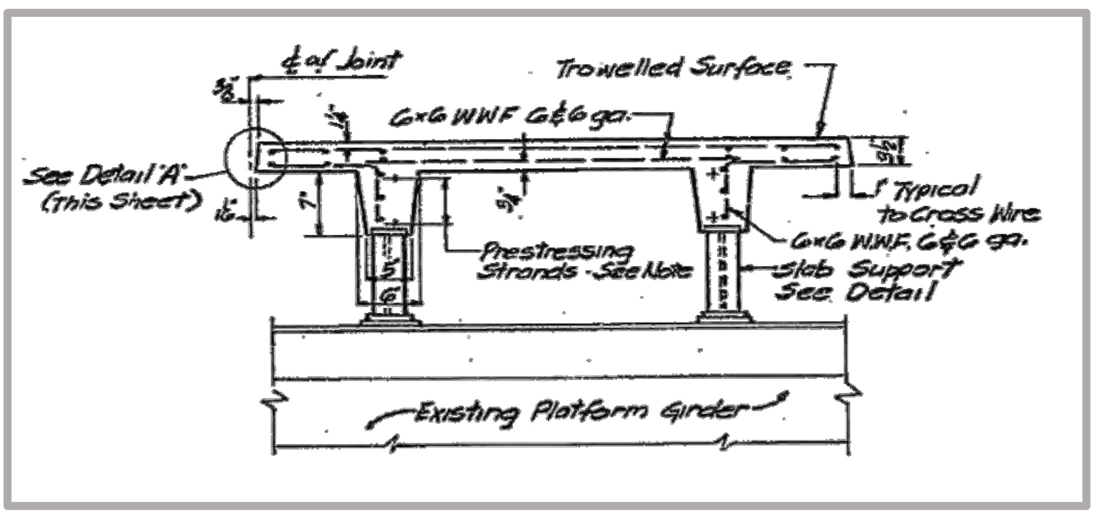

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

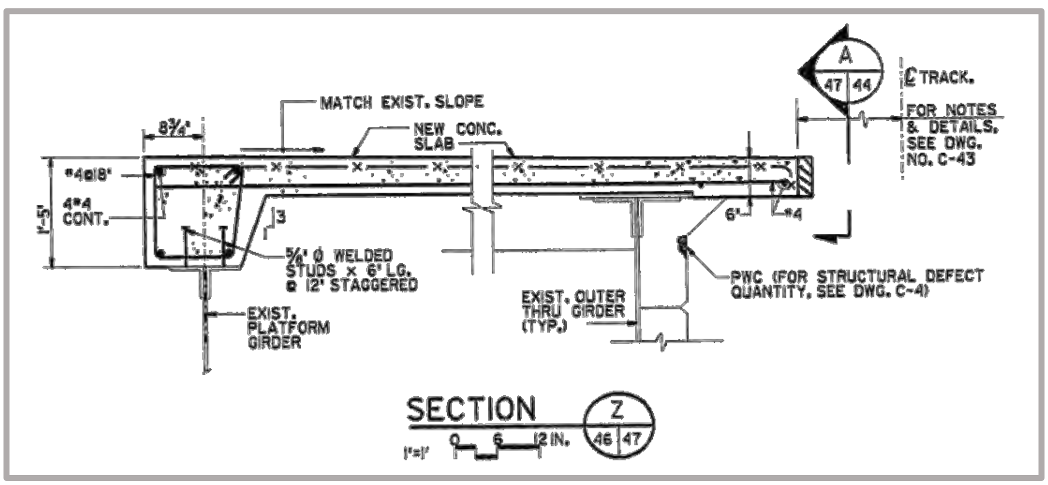

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

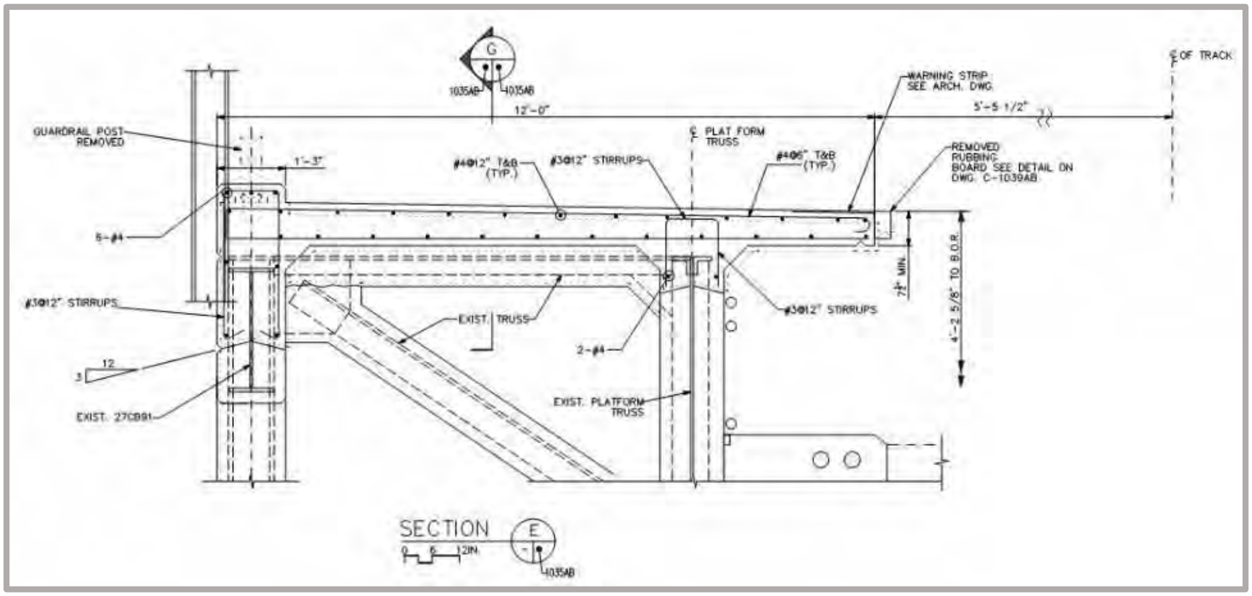

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

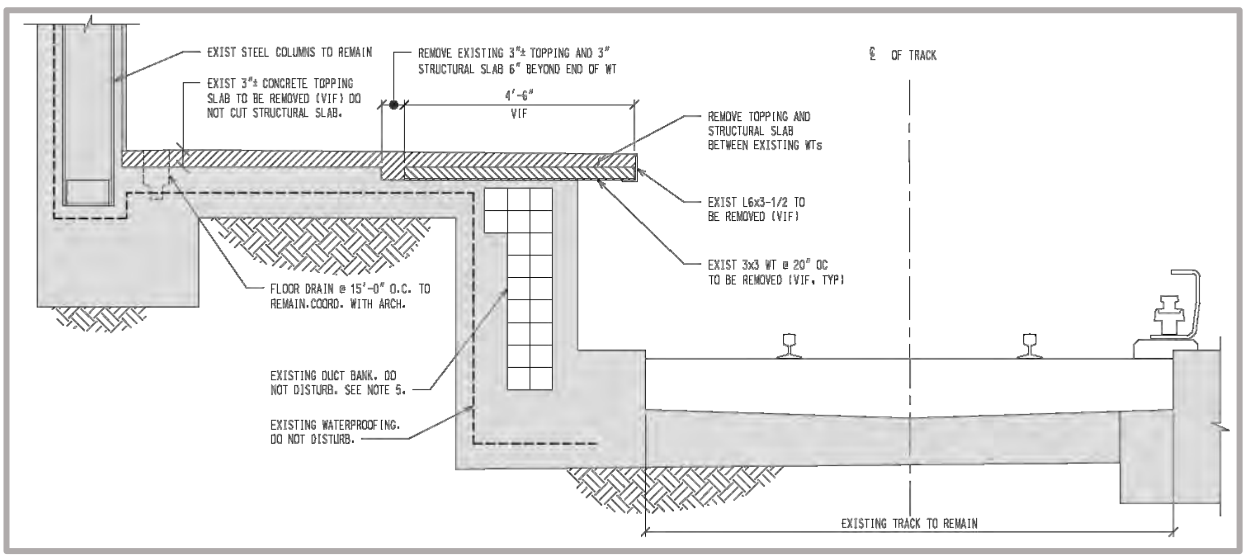

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

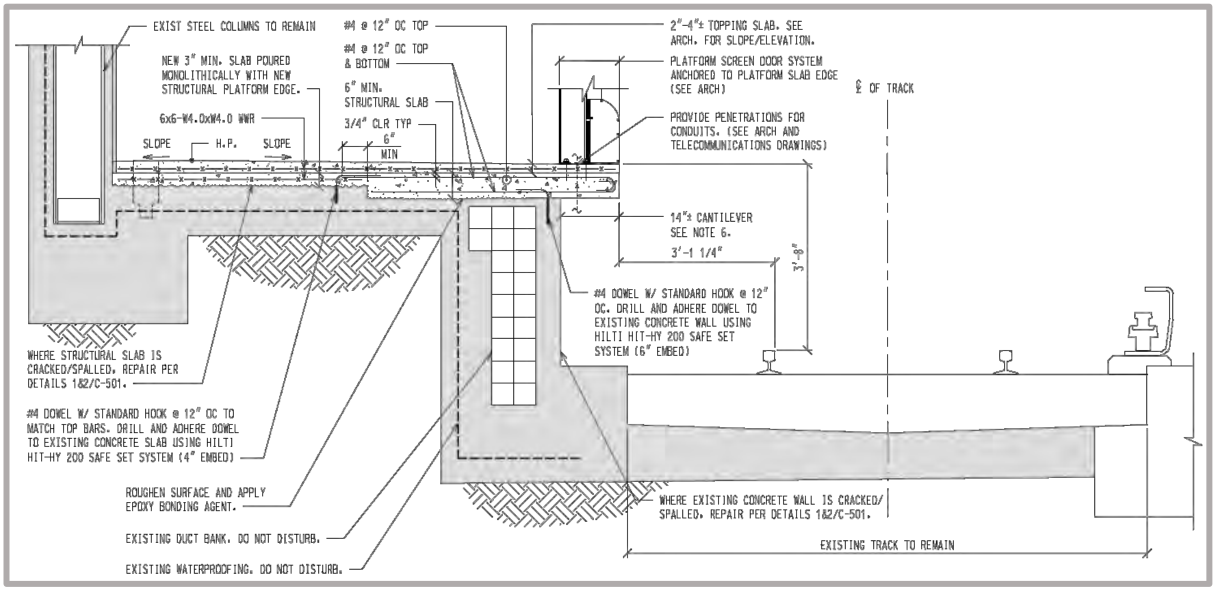

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

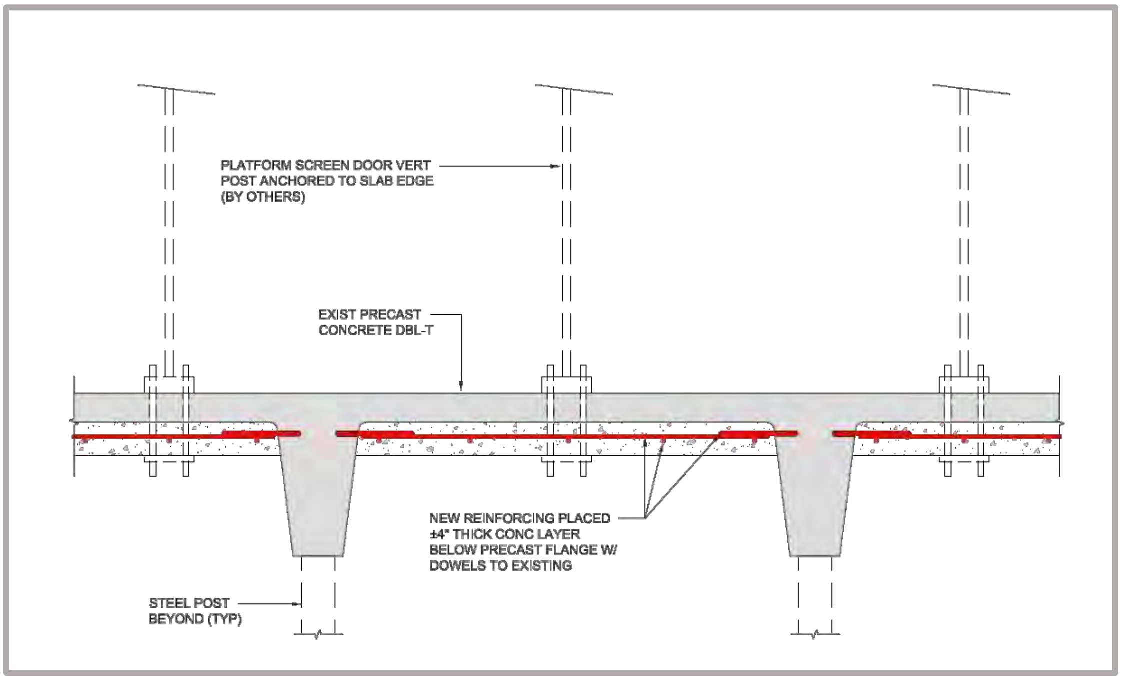

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-4 Line Stations

MTA/NYCT

March 25, 2019

BASIS OF ESTIMATE

1.0 *Description of typical APG / PSD installation:*

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 *Assumptions:*

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-4 Line Stations

MTA/NYCT

March 25, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-4 Line Stations

25-Mar-19

STATION : BERGEN STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	512	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	512	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,024**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,024	LF	7	7,168
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,120	SF	12	61,440
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	103	CY	2,500	257,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,026	EA	25	25,650
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,026	EA	25	25,650
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,024	LF	95	97,280
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,024	LF	15	15,360
26	Remove existing platform tiles	1,024	LF	12	12,288
27	Sawcut existing topping concrete at perimeter of removal area	1,024	LF	5	5,120
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,144	SF	8	49,152
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,024	SF	15	15,360

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	550	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	550	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,100**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	AUTOMATIC PLATFORM GATES [APG's]				
10					
11	Platform edge reconstruction				
12	Demolition				
13	Remove existing polyethylene edge strip	1,100	LF	7	7,700
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,500	SF	12	66,000
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	111	CY	2,500	277,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,102	EA	25	27,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,102	EA	25	27,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-4 Line Stations

25-Mar-19

STATION : 51ST STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	534	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	534	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,067**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,067	LF	7	7,471
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,337	SF	12	64,040
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	108	CY	2,500	270,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,069	EA	25	26,734
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,069	EA	25	26,734
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,067	LF	95	101,397
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,067	LF	15	16,010
26	Remove existing platform tiles	1,067	LF	12	12,808
27	Sawcut existing topping concrete at perimeter of removal area	1,067	LF	5	5,337
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,404	SF	8	51,232
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	520	SF	8	4,160
30	New Work				
31	New concrete topping to match existing	1,067	SF	15	16,010

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-4 Line Stations

25-Mar-19

STATION : BOWLING GREEN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	522	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	516	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,038**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,038	LF	7	7,266
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,190	SF	12	62,280
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	105	CY	2,500	262,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,040	EA	25	26,000
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,040	EA	25	26,000
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,038	LF	95	98,610
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,038	LF	15	15,570
26	Remove existing platform tiles	1,038	LF	12	12,456
27	Sawcut existing topping concrete at perimeter of removal area	1,038	LF	5	5,190
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,228	SF	8	49,824
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	560	SF	8	4,480
30	New Work				
31	New concrete topping to match existing	1,038	SF	15	15,570

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘’ SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: April 5, 2019 Rev. 8/13/2019

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 55 newly evaluated stations, 49 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
    - Limit the ability of a wheelchair to turn within a 5'-0" circle
    - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
    - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the 5-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 11% of the '5' Line Stations. Total implementation cost would be $163.5M for APGs and $136.3M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 6 feasible stations, the aggregate annual maintenance cost would be $5.6M.

Summary Table

(11% Feasible 6/55)

1.0 Station Assessments

1.01 – MR 337 | Nevins Street Station

Summary: *Nevins Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description

Nevins Street Station is a below-grade station with two center / island platforms. The platform structures are cast-in-place concrete. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by these columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the structural columns pose cost prohibitive scenarios.

***Figure 1** – Columns at 20" from platform edge*
Nevins Street Station

1.02 – MR 338 | Atlantic Avenue Barclay Center Station

Summary: *Atlantic Avenue Barclay Ctr. Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Atlantic Avenue Barclay Ctr. is a below-grade station consisting of one center / island platform (the No. 2&3 trains utilize separate side platforms). This report concerns only the No. 4&5 train platform. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Atlantic Avenue Barclay Ctr. Station

Table of Contents

1.03 – MR 342 | Franklin Avenue Botanic Garden Station

Summary: *Franklin Avenue Botanic Garden Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Franklin Avenue Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Franklin Avenue Station

1.04 – MR 343 | Nostrand Avenue / Eastern Pkwy

Summary: *Nostrand Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Nostrand Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

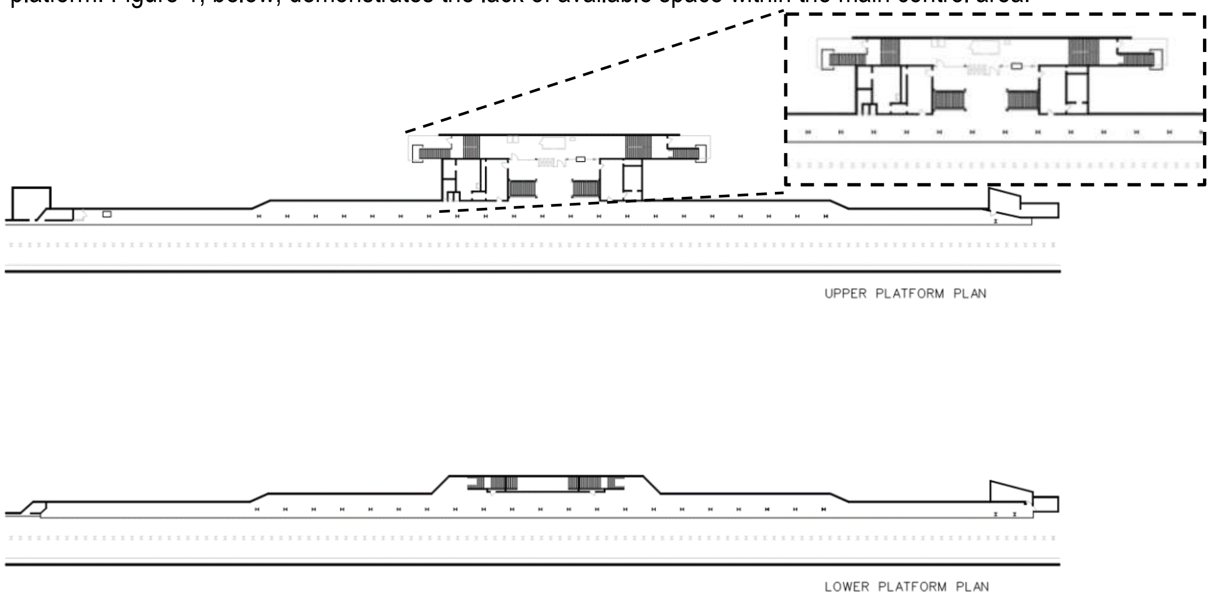

Figure 1 *– Congested/Narrow Station Plan*
Nostrand Avenue Eastern Pkwy

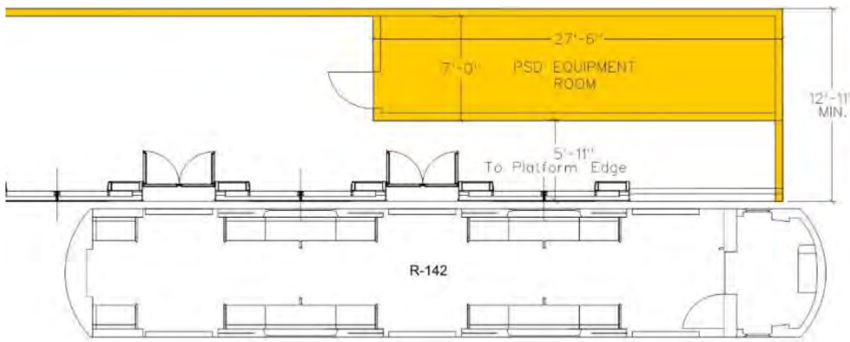

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.05 – MR 344 | Kingston Avenue

Summary: *Kingston Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Kingston Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-10" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

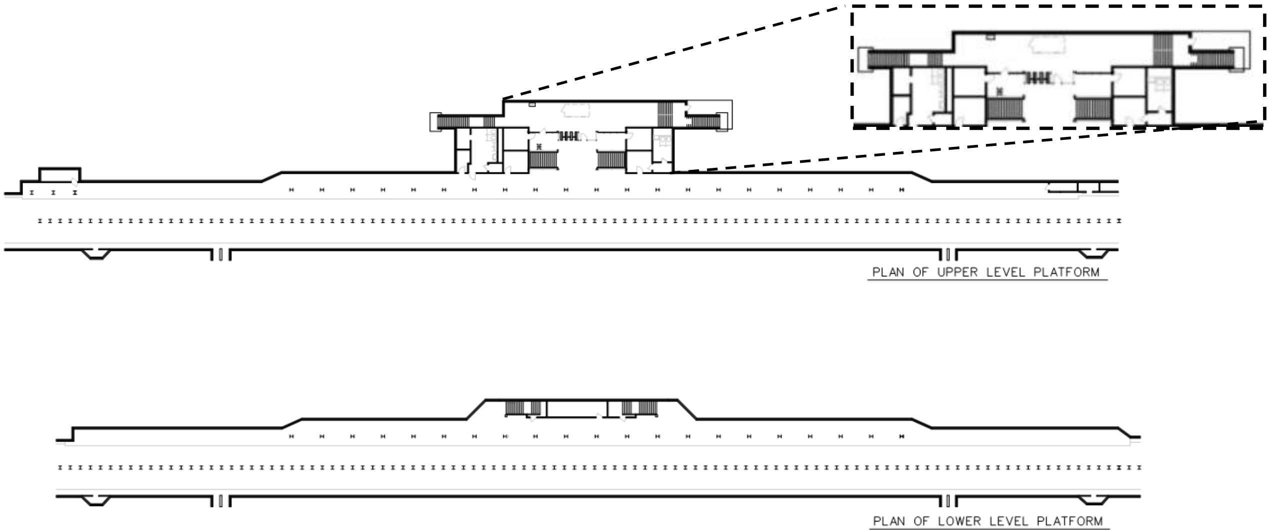

Figure 1 *– Congested/Narrow Station Plan*
Kingston Avenue

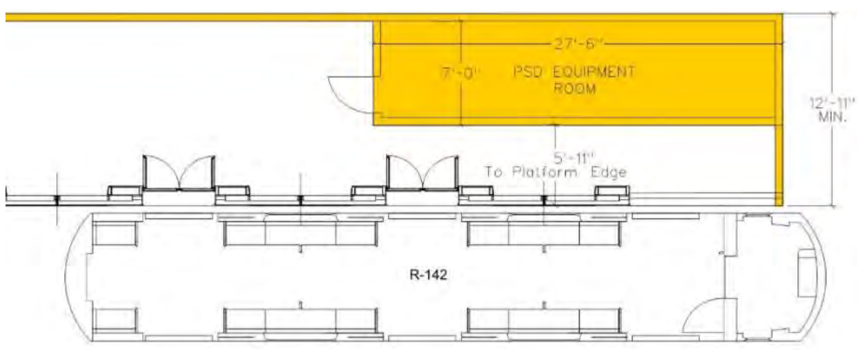

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.06 – MR 345 | Crown Heights / Utica Avenue

Summary: *Crown Heights Station is not feasible for both APGs and PSDs as the columns which are located 12" from the platform edge would impede installation, access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Crown Heights Station is a below-grade station consisting of two center / island platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 12" from the platform edge. This dimension does not allow for installation and maintenance of the 15"-wide APG/PSD system. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 12" from the edge*
Crown Heights Utica Avenue

1.07 – MR 346 | Sutter Avenue

Summary: *Sutter Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Sutter Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 8'-10" to 9'-10". The platforms are straight with one row of columns inset in the windscreen. See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Sutter Avenue Station

Figure 2 *– Precast Slab*
Sutter Avenue Station

1.08 – MR 353 | President Street Station

Summary: *President Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at five platform stairs as the remaining width would be 27" (see figure 1).*

Description

President Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform is approximately 20'-0" throughout. The corridor width at southern end of this platform is 42". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 27" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
President Street Station

1.09 – MR 354 | Sterling Street Station

Summary: *Sterling Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

Sterling Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the length of the platforms along the platform edge. The platform widths are approximately 11-10" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would be required for the installation of both an APG and PSD system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for '5' Line Stations
(Sterling Street Station)

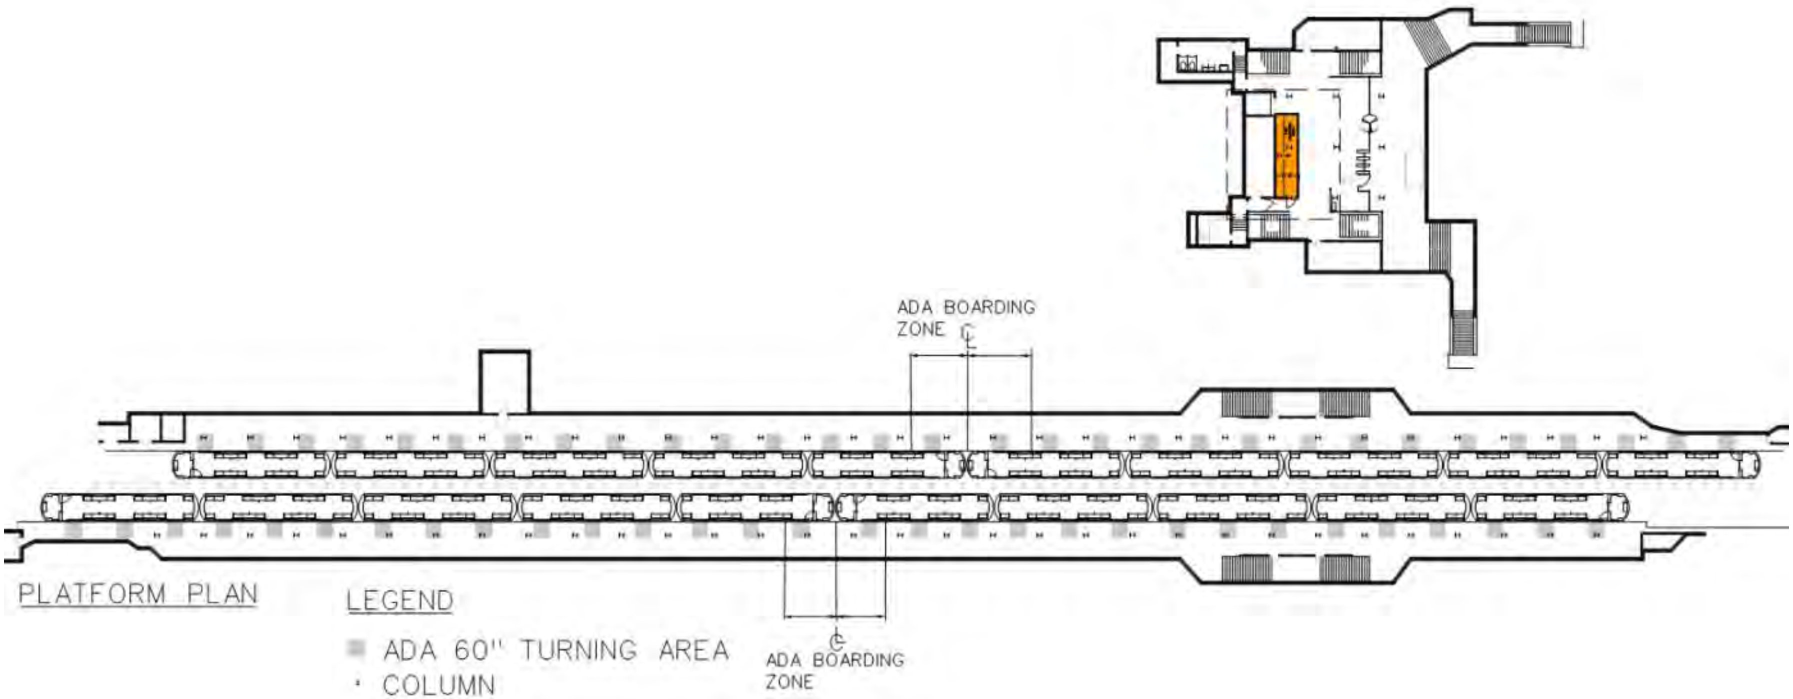

***Figure 1** – Overall Station Plan*
Sterling Street Station

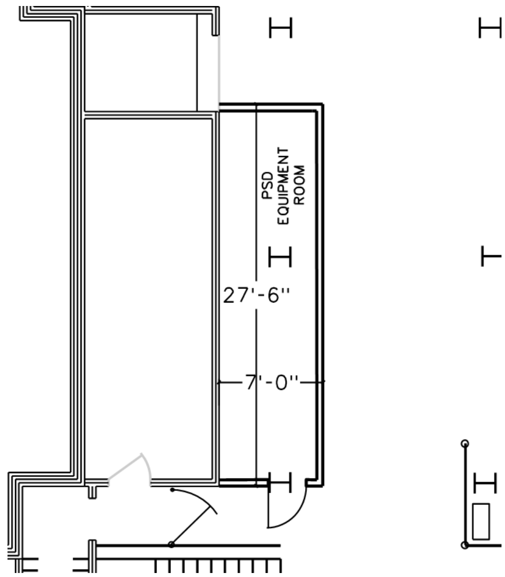

Figure 2 – *PSD Equipment Room 1 Detail*
Sterling Street Station

Figure 3 – *Typical platform view*
Sterling Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:
An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $26.7M to install APGs and $33.4M to install PSDs (See Appendix E)

1.10 – MR 355 | Winthrop Street Station

Summary: *Winthrop Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

The Winthrop Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-8' to 11'-10". The corridor width at the southbound end of the platforms is 3'-8". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Winthrop Street Station

1.11 – MR 356 | Church Avenue Station

Summary: *Church Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

Church Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns along each platform edge. The platform width varies from 7'-10" to 11'-10" throughout. Due to the extremely limited width of the existing platforms and control areas, there is no available space for the equipment room. Figure 2 below shows the minimum width required for construction of a PSD equipment room if placed on the platform. Figure 1, below, demonstrates the lack of available space within the southbound control area. The northbound control area is similar.

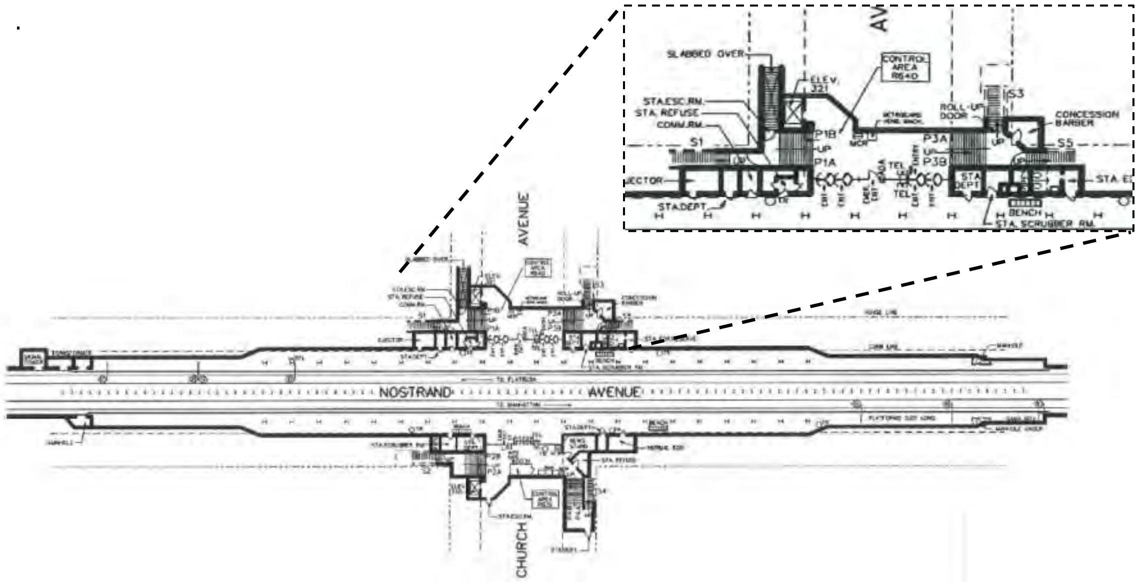

***Figure 1 –** Congested / Narrow Station Plan*
Church Avenue Station

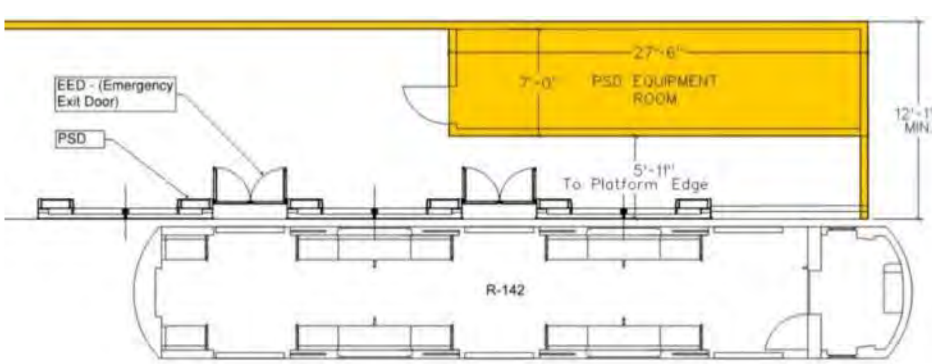

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
Church Avenue Station

1.12 – MR 357 | Beverly Road Station

Summary: *Beverly Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the northbound platform as the existing width is 5'-9" (see figure 1).*

Description

Beverly Road Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-9' to 11'-10".

Platform width at the north end of the northbound platform is 5'-9" or 69". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
Beverly Road Station

1.13 – MR 358 | Newkirk Avenue Station

Summary: *Newkirk Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the both platforms as the existing width is 5'-9" (see figure 1).*

Description

Newkirk Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-9' to 11'-10".

Platform width at the ends of the northbound & southbound platform are 5'-9" or 69". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

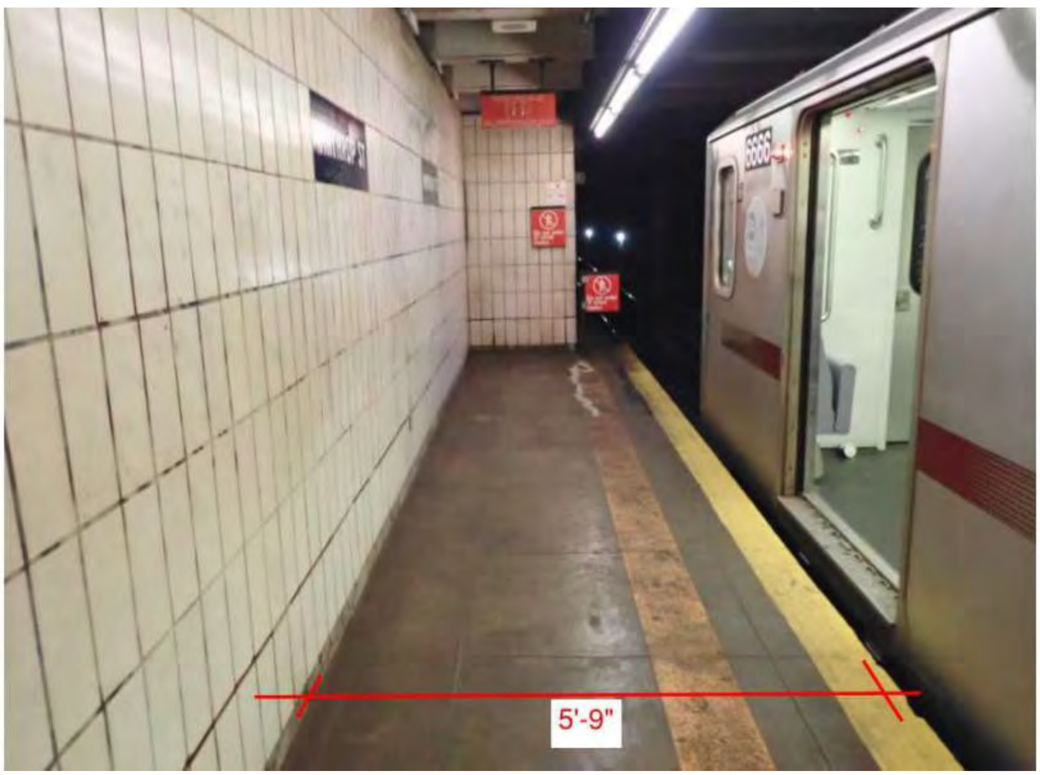

***Figure 1** – Non-Compliant egress condition*
Newkirk Avenue Station

Table of Contents

1.14 – MR 359 | Flatbush Avenue Brooklyn College Station

Summary: *Flatbush Avenue Brooklyn College Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

The Flatbush Avenue Brooklyn College Station is a below-grade terminus station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the northern end of the northbound platform is 2'-4". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 13" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Flatbush Avenue Brooklyn College Station

1.15 – MR 391 | 138th Street Grand Concourse

Summary: *138th Street Grand Concourse Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 138th Street Grand Concourse Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-6". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
138th Street Grand Concourse Station

1.16 – MR 392 | 125th Street

Summary: *125th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

125th Street Station is a below-grade station with two levels of straight center / island platforms. The no. 4 train utilizes both the upper and lower level. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 29'-8". At the lower platform, the implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The upper platform is infeasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 2 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA clearance*
North end of lower platform; 125th Street Station

***Figure 2** – Columns at 16" from platform edge*
South end of upper platform

1.17 – MR 393 | 116th Street

Summary: *116th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

116th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-8" to 11'-10". There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

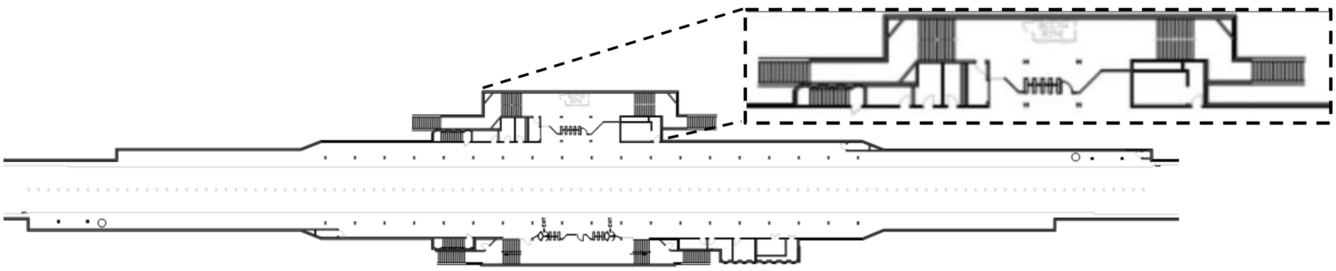

Figure 1 *– Congested/Narrow Station Plan*
116th Street Station

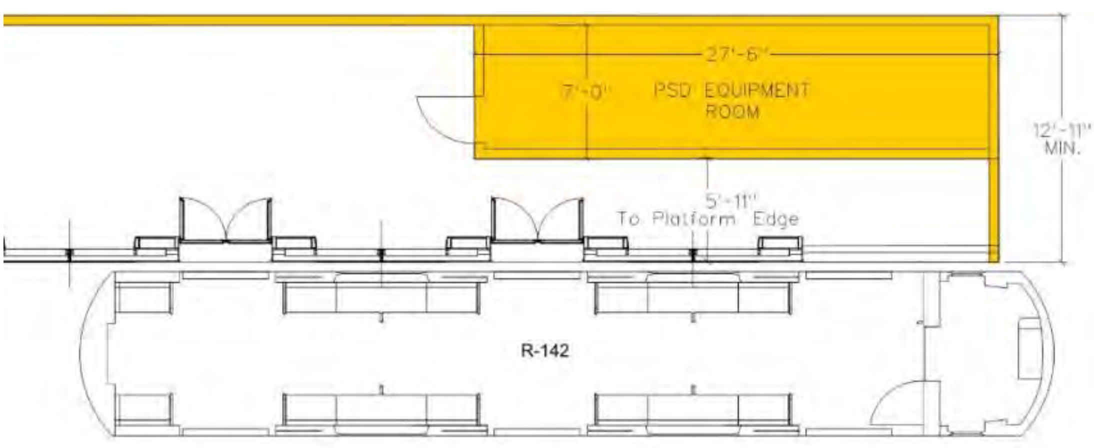

Figure 2 – *Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.18 – MR 394 | 110th Street

Summary: *110th Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

110th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. Platform widths vary from 7'-8" to 8'-0".

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the main control area.

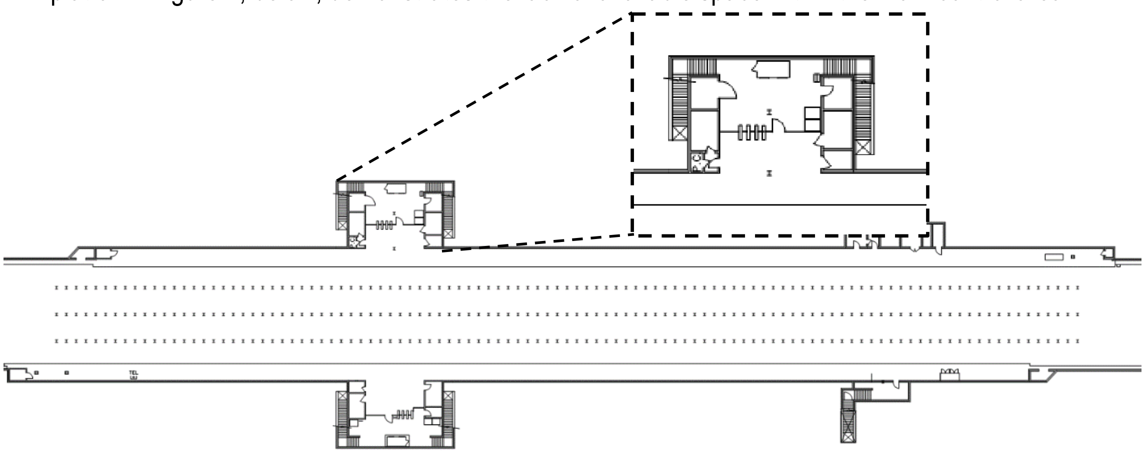

***Figure 1** – Congested/Narrow Station Plan*
110th Street Station

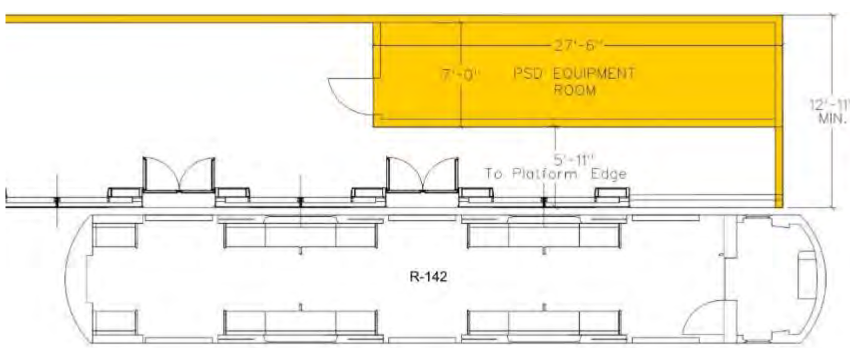

***Figure 2 –** Diagram demonstrating minimum platform width dimensions*
(A Division train shown; B Division requires same dimension

1.19 – MR 395 | 103rd Street

Summary: *103rd Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

103rd Street Station is a below ground station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns located throughout the platforms. The platform widths are approximately 7-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the mezzanine control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

103rd Street Station

Table of Contents

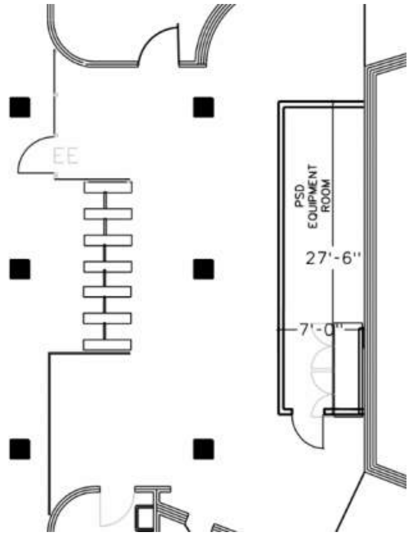

Figure 2 *– PSD Equipment Room 1 Detail*
103rd Street Station

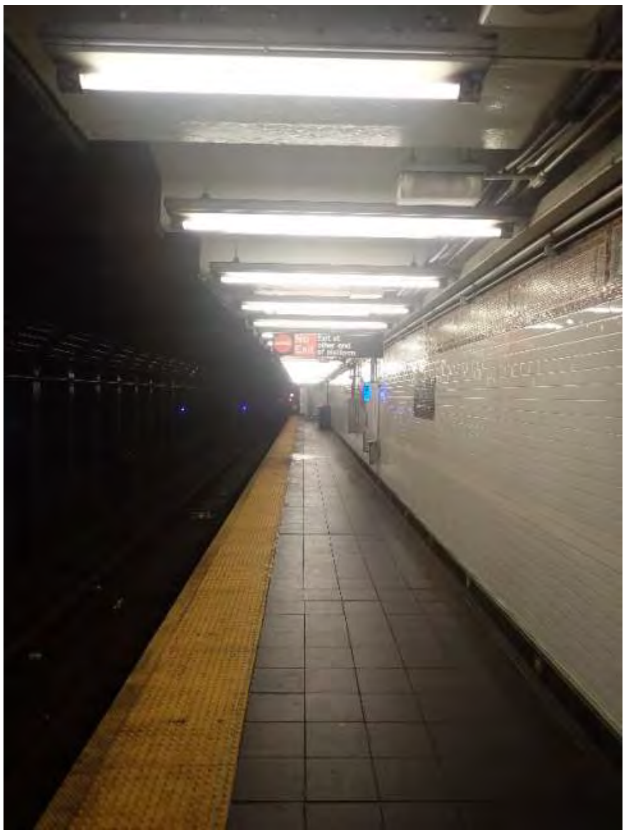

Figure 3 *– Typical platform view*
103rd Street Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal service)

Station Name	103rd Street
Peak Demand Load from ConEd Report, (kW)	26.8
Apparent Power (kVA)	33.5
Station Peak Demand Load, Max Current, (A)	93.1
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	251.2
Station Service Power Capacity, (Main SB or SG Rating), (A)	400.0
Service Spare Capacity, (A)	148.9
Is Electrical Service Adequate?	**Yes**
Notes	Service rating of 400A is based on field observations. Station has only (1) meter readings for Normal service. The station Reserve meter was NOT accessible during field survey. (No meter in Reserve EDR) 1 Line diagram provided is not current.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $34.5M to install PSDs (See Appendix E)

Table of Contents

1.20 – MR 396 | 96th Street

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 5'-0" (see figure 1).*

Description

96th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 12'-10".

The platform width at the end of the southbound platform is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

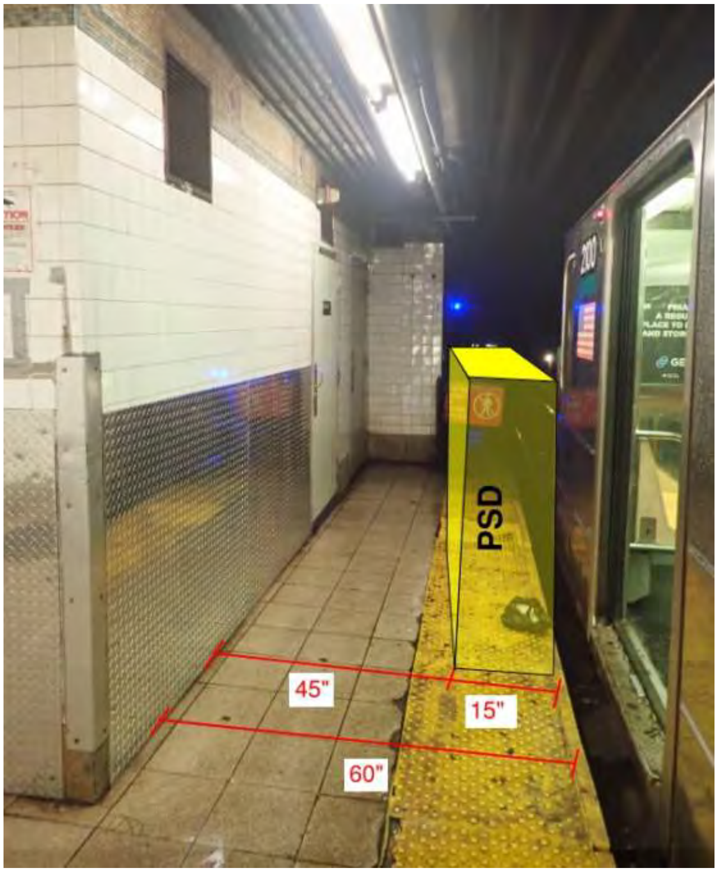

Figure 1 *– Non-Compliant egress condition*
96th Street Station

1.21 – MR 397 | 86th Street

Summary: *86th Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the center stairs as the remaining width would be 31" (see figure 1).*

Description

The 86th Street Station is a below-grade station consisting of two side platforms on two levels. The No. 4 service normally runs at the lower level, with night service on the upper level. At the upper level, the platforms are approximately 13'-8" wide. The platforms are straight with one rows of columns at 46" from the edge of the platform. The implementation of a platform edge barrier would reduce this width to 31" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The 86th Street lower level is infeasible due to lack of space for a PSD equipment room. The introduction of an equipment room on the lower platform would create 24" pinch points at the columns which do not comply with the minimum 32" required by ADA.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA dimension*
86th Street Station

1.22 – MR 398 | 77th Street

Summary: *77th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 77th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-8". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
77th Street Station

Table of Contents

1.23 – MR 399 | 68th Street Hunter College

Summary: *68th Street Hunter College Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of both platforms as the existing width is 4'-2" (see figure 1).*

Description

68th Street Hunter College Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-2' to 11'-10".

Platform width at the southbound end of the northbound & southbound platform is 4'-2" or 50". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

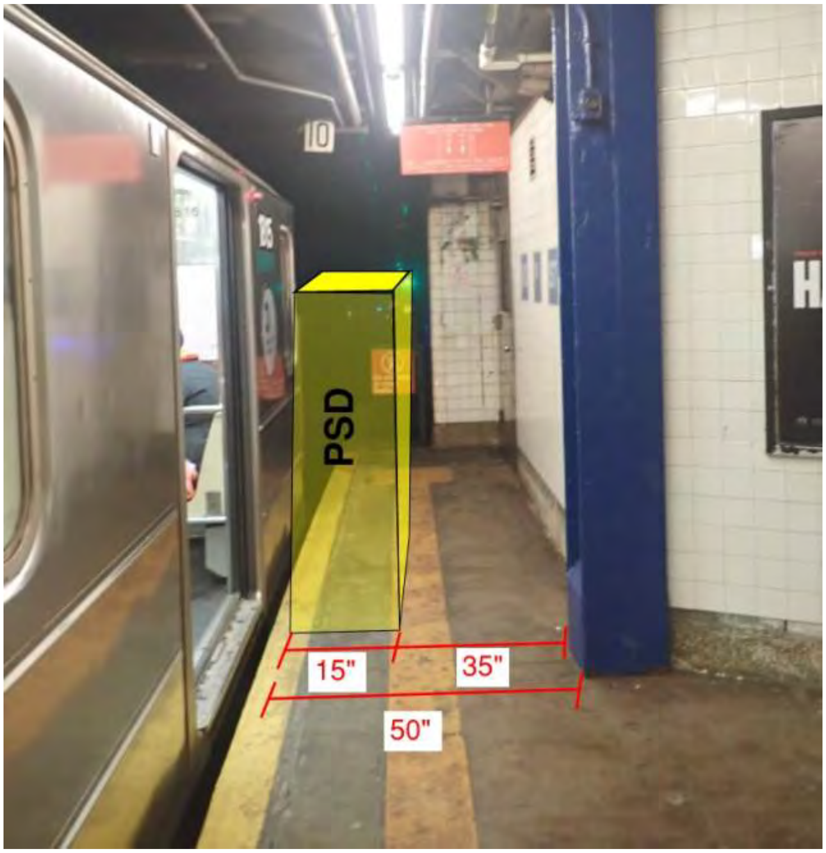

***Figure 1** – Non-Compliant egress condition*
68th Street Hunter College Station

1.24 – MR 400 | 59th Street

Summary: *59th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 59th Street Station is a below-grade station with two levels of two straight side platforms. The No. 4 service runs normally on the lower platform, with night service on the upper platform. The upper level platform will be the subject of a future report for the No. 6 line. The platform structures are cast-in-place concrete. The width of the lower level platforms ranges from 3'-4' to 13'-0". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of a 32" pinch point. The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

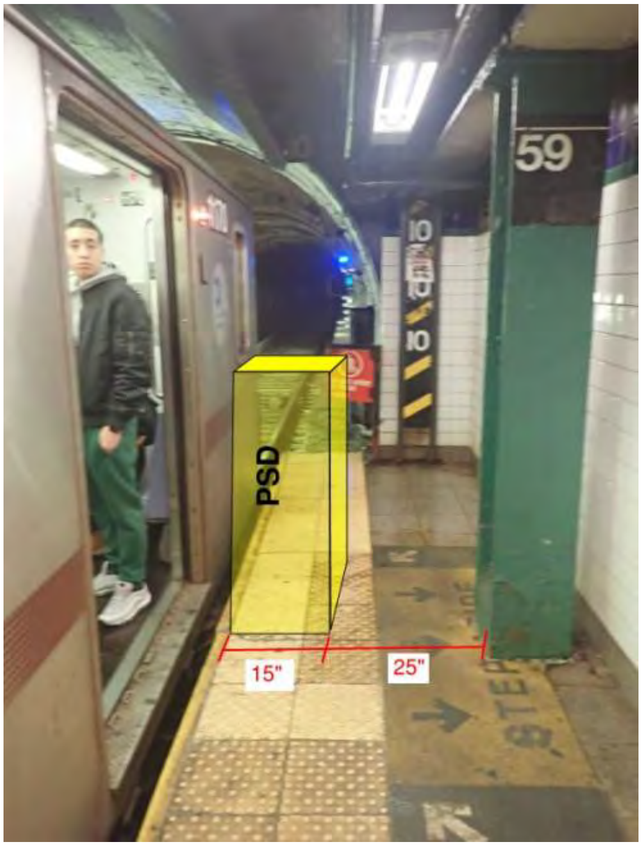

Figure 1 *– Non-Compliant egress condition*
59th Street Station- lower level

1.25 – MR 402 | 42nd Street Grand Central

Summary: *42nd Street Grand Central Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 42nd Street Grand Central Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-10' to 24'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

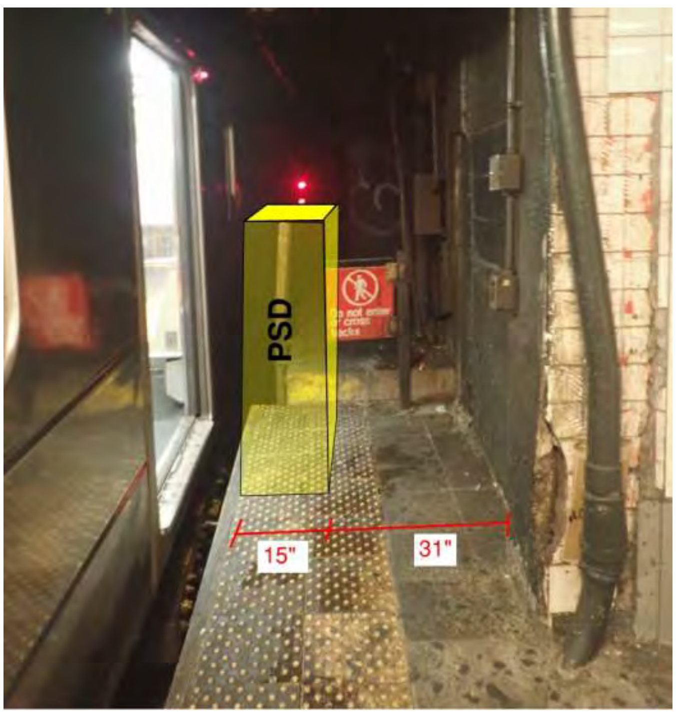

Figure 1 *– Non-compliant ADA condition*
42nd Street Grand Central Station

1.26 – MR 406 | 14th Street Union Square

Summary: *14th Union Square Station is not feasible for both APGs and PSDs due to the presence of platform edge gap fillers located at all southbound platform edges. The existing gap fillers are a dynamic assembly that extends the platform edge when a train arrives, and recedes when the train departs. This moving assembly prevents the installation of a static PSD system. Please see figure 1 for reference.*

Description:

Due to the sharp curvature of the platforms at 14th Street Union Square, platform edge gap fillers are necessary to bridge the gap between the current rolling stock's doors and the platform edge.

Figure 1 –*Platform Edge Gap Fillers*
14th Street Union Square Station

Table of Contents

1.27 – MR 411 | Brooklyn Bridge City Hall

Summary: *Brooklyn Bridge City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the center stairs as the remaining width would be 17" (see figure 1).*

Description

The Brooklyn Bridge City Hall Station is a below-grade station consisting of two center / island platforms. The platforms are approximately 15'-6" to 21'-2" wide. The platforms are mildly curved with two rows of columns at 32" from the edge of the platform. The implementation of a platform edge barrier would reduce this width to 17" or less* which would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Brooklyn Bridge City Hall Station

1.28 – MR 412 | Fulton Street

Summary: *Fulton Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Fulton Street Station is a below-grade station with two side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edge. Column faces measure approximately 3'-2" from the platform edge. The platform widths range from approximately 7'-6" to 19'-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the southbound platform of the station (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past five years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Fulton Street Station

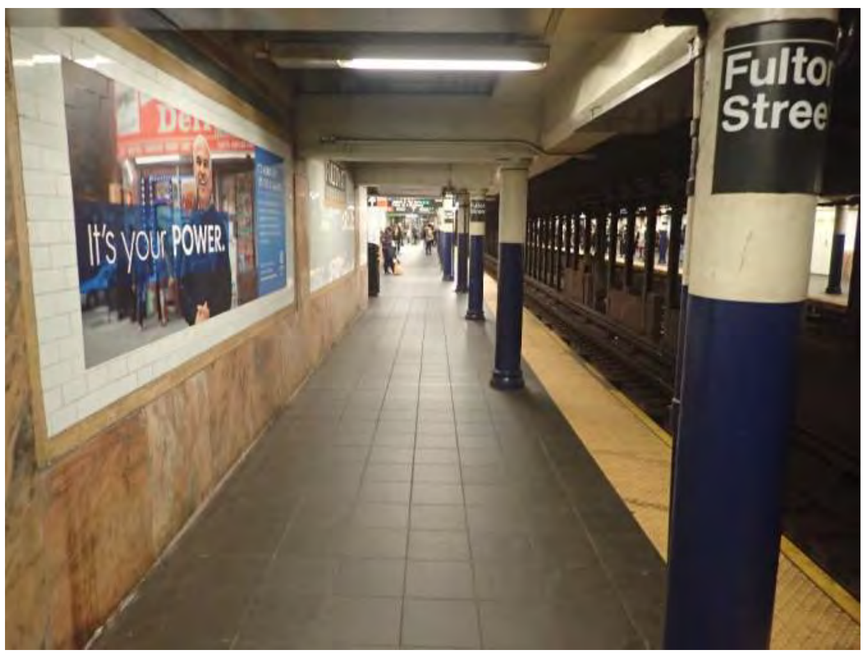

Figure 3 – Typical platform view
Fulton Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted both parallel and perpendicular to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & Table 2 please see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal Service. SS-3)

Station Name	Fulton Street
Peak Demand Load from ConEd Report, (KW)	231.4
Apparent Power (kVA)	289.2
Station Peak Demand Load, Max Current, (A)	803.3
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	961
Station Service Power Capacity, (Main SB or SG Rating), (A)	9222.22
Service Spare Capacity, (A)	8261
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey. 1 line diagram provided does not match field survey. Station has total (3) services (SS-1,SS-2 & SS-3) @ 480 Volt and has (3) associated meters. The 480 V data is converted to 208 V units. This analysis is for **Normal service** meter reading provided for Service 'SS-3' @ Rm# T5-09.

***Table 1**. Normal Service Power Capacity Analysis*

Station

Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	5104
Station Service Power Capacity, (Main SB or SG Rating), (A)	18444.44
Service Spare Capacity, (A)	13341
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey. 1-line diagram provided does not match field survey. Station has total (3) services (SS-1,SS-2 & SS-3) @ 480 Volt and has (3) associated meters.The 480 V data is converted to 208 V units. This analysis is for combined **Normal & Reserve service** meter reading provided for Service 'SS-1' @ Rm# T5-09 and Service 'SS-2' @ Rm# T5-08.

***Table 2**. Norma l Reserve Service Power Capacity Analysis*

Historic Restrictions:
This station is a designated historical place. As such, any capital improvement will be subject to review by the State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.5M to install APGs and $34.6M to install PSDs (See Appendix E)

1.29 – MR 413 | Wall Street

Summary: *Wall Street Station is not feasible for both APGs and PSDs as the columns which are located 20" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Wall Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 20" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 20" from the edge*
Wall Street Station

1.30 – MR 414 | Bowling Green

Summary: *Bowling Green Station is feasible for both APGs and PSDs. Two structural columns will need to be relocated due to their proximity to the platform edge. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Bowling Green Station is a below-grade station with one side platform & one center / island platform that has only one active platform edge (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edges. Column faces measure approximately 2'-2" from the platform edge. Two columns on the southbound platform measure 17" from the platform edge. The platform widths range approximately from 14-0" – 24'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the northbound platform of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are approximately tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Historic Restrictions:
This station is a designated historical place for its original entrance & control house. As such, any capital improvement will be subject to review by the State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.3M to install APGs and $33.8M to install PSDs (See Appendix E)

1.31 – MR 415 | Borough Hall Station

Summary: *Borough Hall Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Borough Hall Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*

1.32 – MR 417 | 238th Street Nereid Avenue Station

Summary: *238th Street Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The 238th Street Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 12'-0" to 12'-4". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

1.38 – MR 423 | Allerton Avenue Station

Summary: *Allerton Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Allerton Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 12'-0" to 12'-6". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Allerton Avenue Station

Figure 2 *– Precast Slab*
Allerton Avenue Station

1.39 – MR 424 | Pelham Parkway Station

Summary: *Pelham Parkway Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Pelham Parkway Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 12'-8" to 13'-10". The platforms are straight with cantilevered beams supporting their respective station canopies. See figure 1 & 2 for reference.

Summary: *Jackson Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B and figure 1).*

Description

The Jackson Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 6'-6" to 14'-0". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Jackson Avenue Station

Figure 2 *– Precast Slab*
Jackson Avenue Station

1.49 – MR 434 | 3rd Avenue 149th Street Station

Summary: *3rd Avenue 149th Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

3rd Avenue 149th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
3rd Avenue 149th Street Station

1.50 – MR 435 | 149th Street Grand Concourse Station

Summary: *149th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met as the remaining width would be 35" (see figure 1).*

Description

The 149th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the western ends of the platforms is 4'-2". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 35" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
149th Street Station

1.51 – MR 442 | Eastchester Dyre Avenue

Summary: *Eastchester Dyre Avenue Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

The Eastchester Dyre Avenue Station is an embankment station with one straight center island platform. The platform structure is cast-in-place concrete. The platform width is 14'-10" throughout. Due to the limited width of the existing platform, there is no available space for the equipment room. Figure 2 below shows the minimum width required for a center/island platform (19'-4") for construction of a PSD equipment room on a station platform. Figure 1, below shows the station plan.

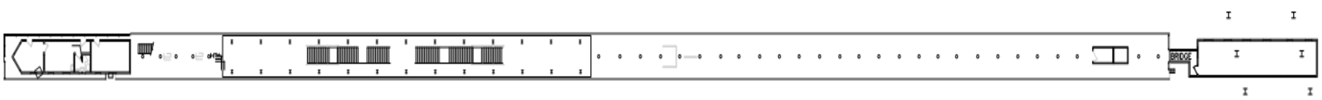

Figure 1 *– Congested/Narrow Station Plan*
Eastchester Dyre Station

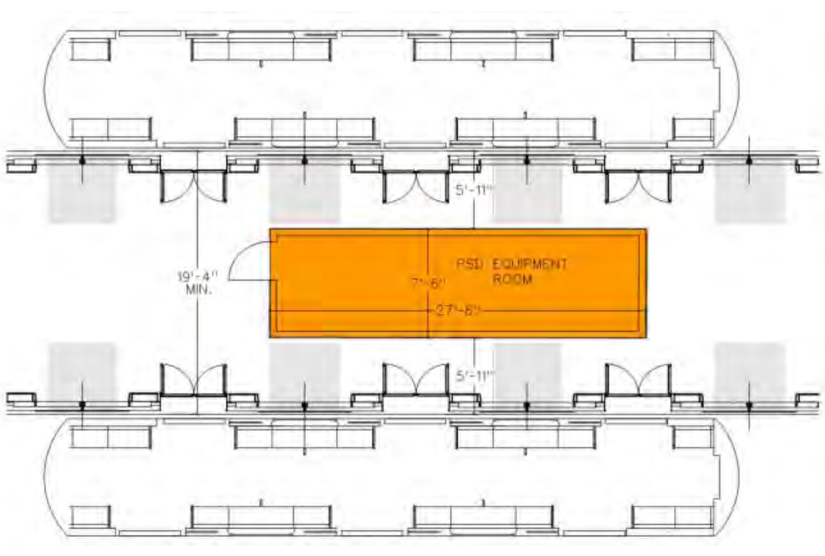

Figure 2 – *Diagram demonstrating minimum platform width dimensions for center/island platform (A Division train shown; B Division requires same dimension*

1.52 – MR 443 | Baychester Avenue

Summary: *Baychester Avenue Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Baychester Avenue Station is an embankment station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. The canopies cover only 40% of the platform length. There are columns located only at the canopies, set against the back wall of the platform. The platform widths are approximately 13'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 60% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the southern end of the northbound platform station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would at a minimum be required for the installation of an APG system.

Baychester Avenue

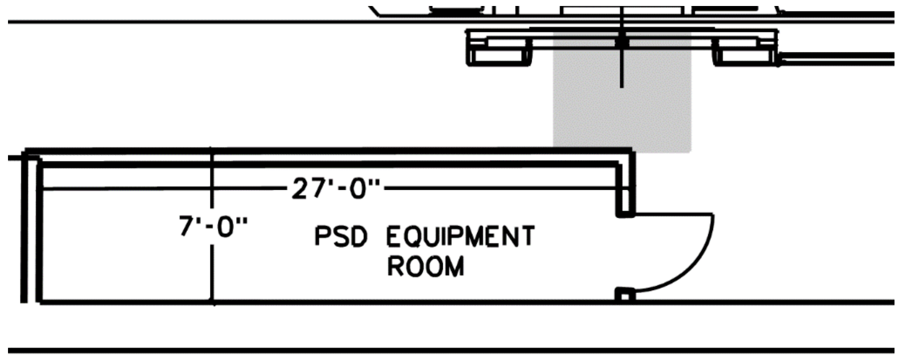

Figure 2 *– PSD Equipment Room 1 Detail*
Baychester Avenue Station

Figure 3 *– Typical platform view*
Baychester Avenue Station

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the back of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Baychester Avenue
Peak Demand Load from ConEd Report, (kW)	39.2
Apparent Power (kVA)	49.8
Station Peak Demand Load, Max Current, (A)	138.2
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	296
Station Service Power Capacity, (Main SB or SG Rating), (A)	400 (Estimated)
Service Spare Capacity, (A)	104
Is Electrical Service Adequate?	**Yes**
Notes	This analysis is for **Normal service**. Service rating is based on field survey photos and it is safe to assume 400A Service equipment. Only (1) meter readings for Normal service provided. The station Reserve Service was NOT accessible during field survey. (No meter reading for Reserve Service provided). 1 Line diagram provided is for Reserve Service and is not applicable to Normal Service.

***Table 1**. Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.1M to install APGs (See Appendix E).

1.53 – MR 444 | Gun Hill Road Station

Summary: *Gun Hill Road Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the northbound platform as the existing width is 5'-8" (see figure 1)..*

Description

The Gun Hill Road Station is an embankment station with two side platforms. The platform structures are cast in place concrete. The platforms are straight with one row of columns along the back wall. The platforms widths are approximately 13'-0" throughout, with the exception of the north end under the mezzanine where both platform widths are reduced to 5'-8". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

Figure 1 *– Area of Non-compliant egress width*
Gun Hill Road Station

1.54 – MR 445 | Pelham Parkway Station

Summary: *Pelham Parkway Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the center of each platform as the existing width is 4'-4" (see figure 1).*

Description

The Pelham Parkway Station is a below ground station with two center / island platforms. Normal train service utilizes only the local (outer) side of each island platform. The platform structures are cast-in-place concrete. The platforms are straight with one row of columns at the center. The width of the platforms varies from approximately 14'-10" to 16'-10". At the center of the platforms, stairs and electrical rooms are constructed at 4'-4" from the outside platform edge (normal service platform) and 3'-4" from the inside platform edge. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

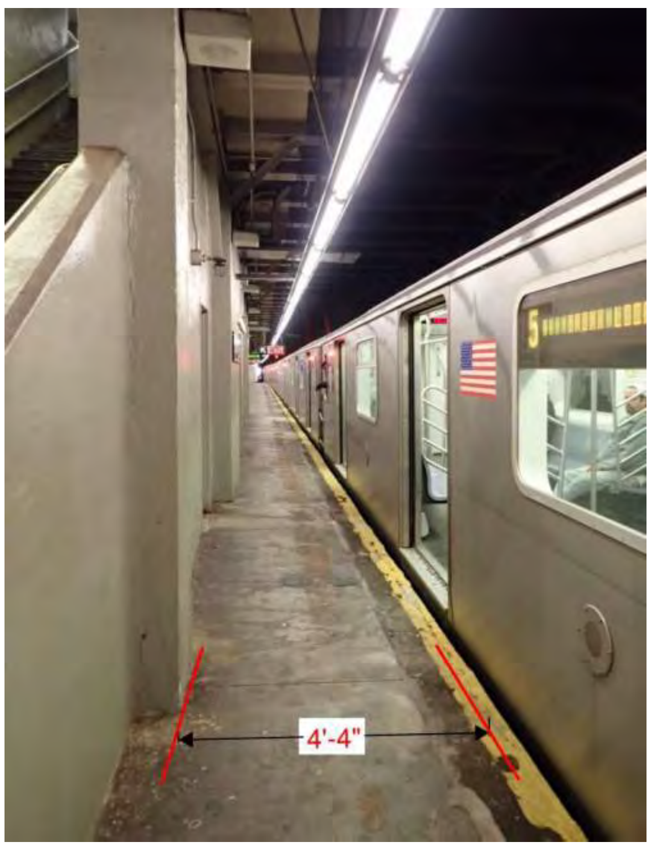

Figure 1 – *Area of Non-compliant egress width*
Pelham Parkway Station

1.55 – MR 446 | Morris Park Station

Summary: *Morris Park Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Morris Park Station is an open cut station with two straight side platforms. The platform structures are cast in place concrete. There are no columns throughout the platforms. The platform widths are approximately 13'-0" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy covers only 70% of the platform length. See figure 1 & 2 for reference.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 30% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the southern end of the northbound platform station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would at a minimum be required for the installation of an APG system.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> - *a. Column location in relation to the platform edge*
> - *b. Platform edge clearance adjacent to stairs and other impediments*
> - *c. Impacts to ADA path of travel and boarding areas*
> - *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> - *e. Sufficient platform width*
> - *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> - *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> - *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> - *c. Confirmation of adequate power for PSD/APG/RPSDs*
> - *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> - *e. Determination of communications requirements, availability and cost*
> - *f. Determination of gap detection and entrapment avoidance technology requirements*
> - *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

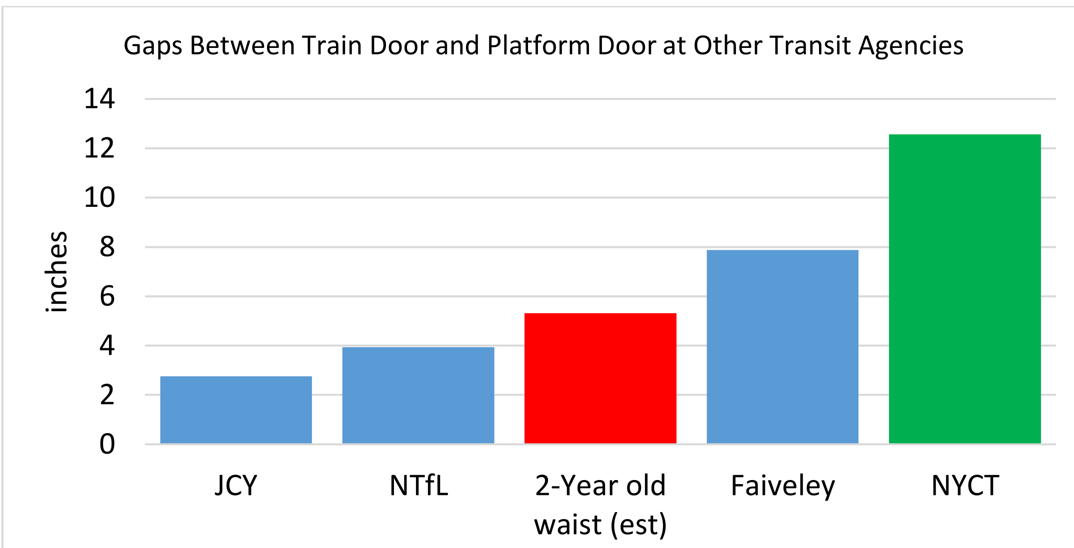

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

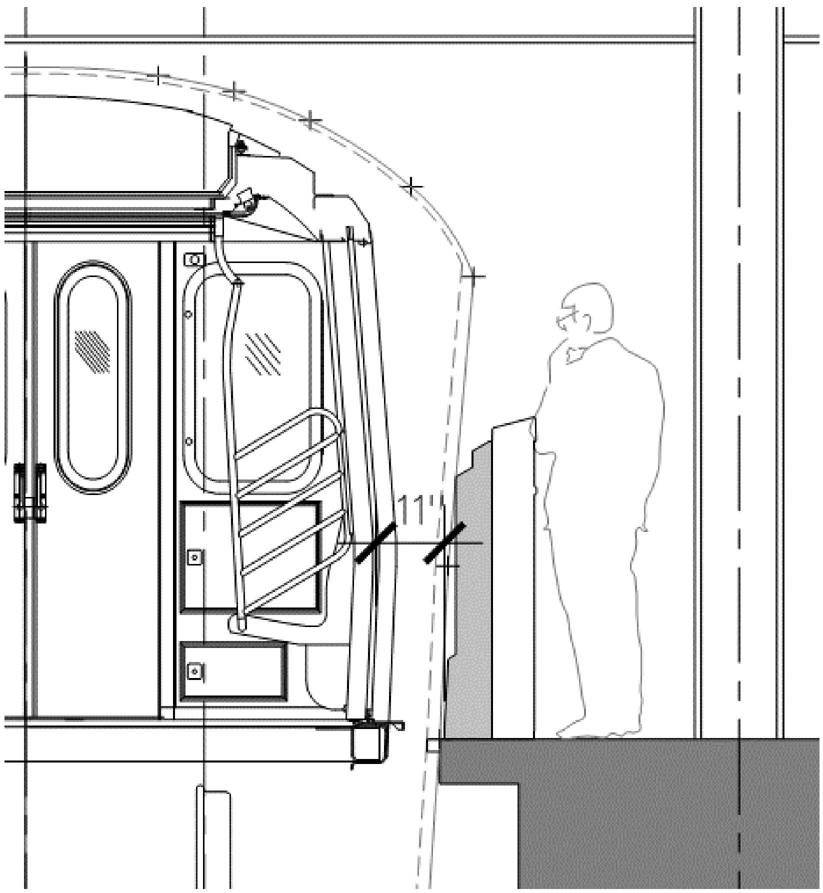

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

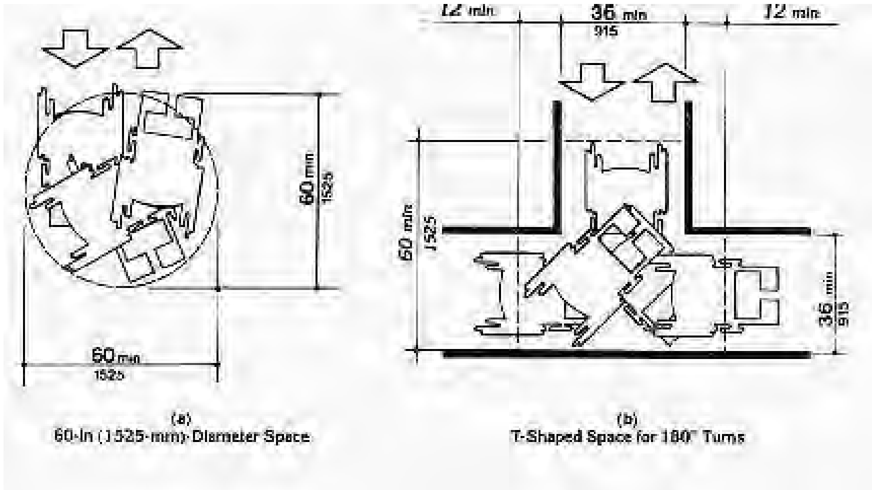
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

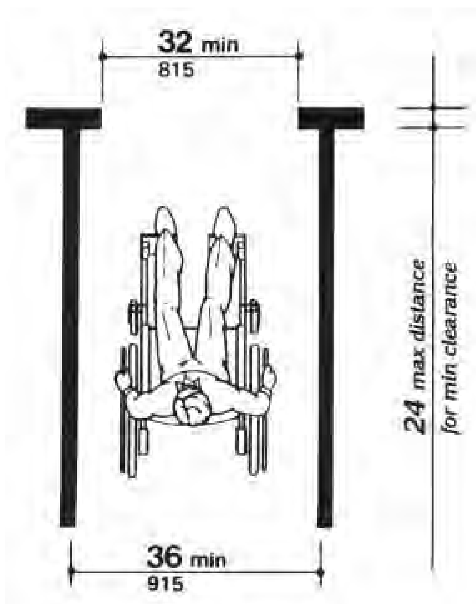


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

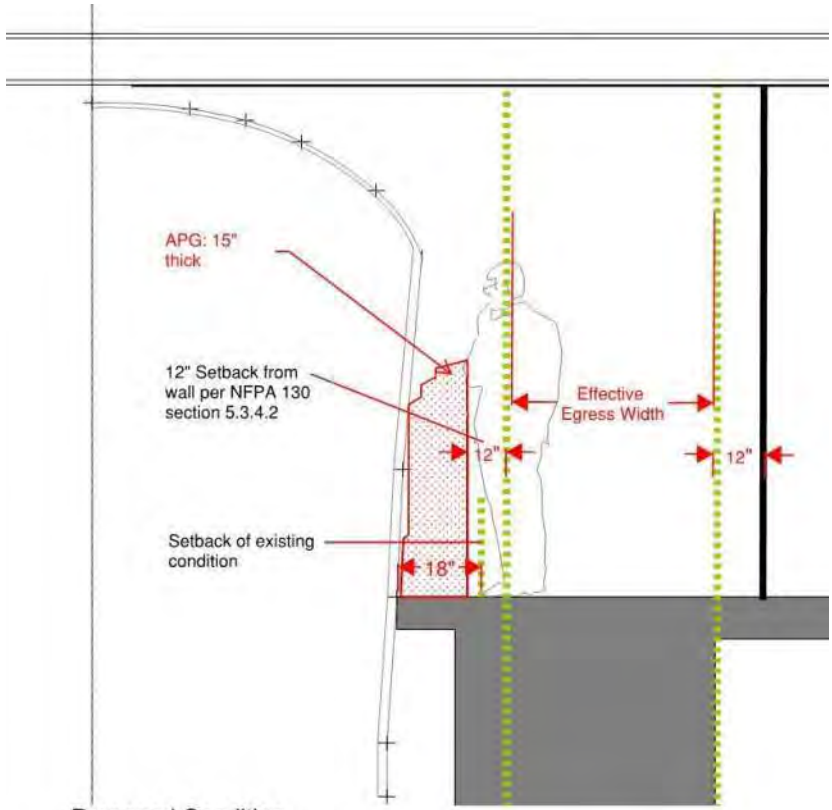
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15” of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

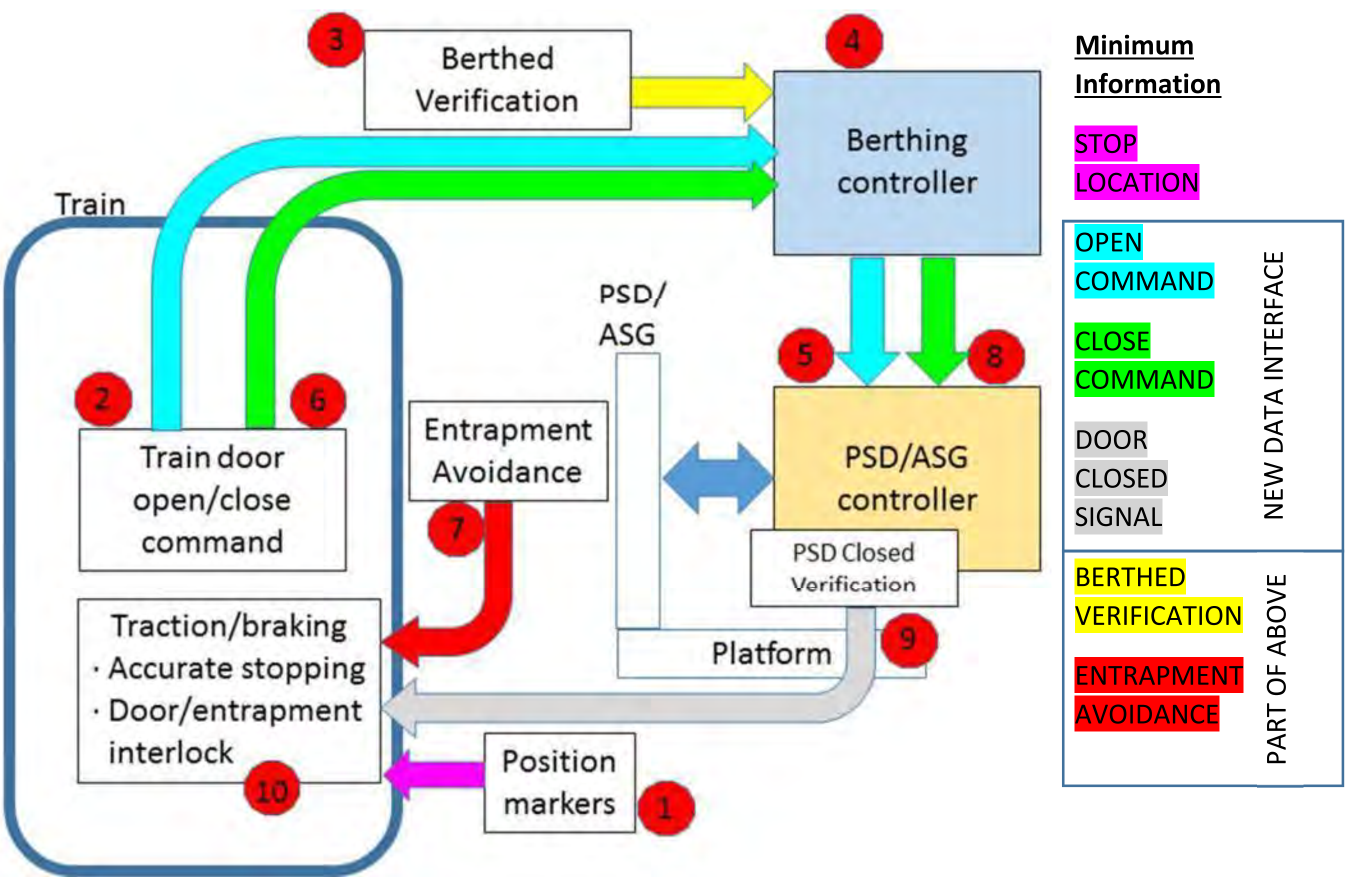
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

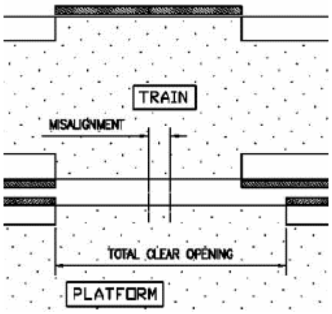
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5” clear opening, a design for NY should meet the ADA Accessibility Guideline of 36”.

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a ‘distance totem’ which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy’s COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

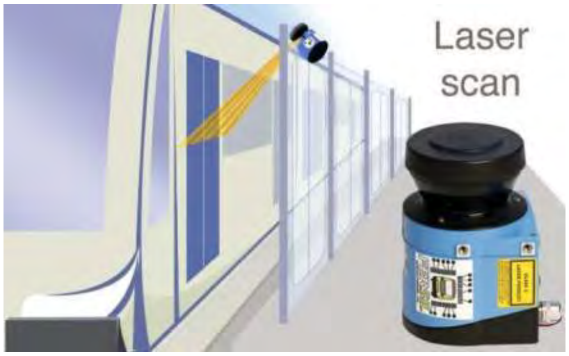
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

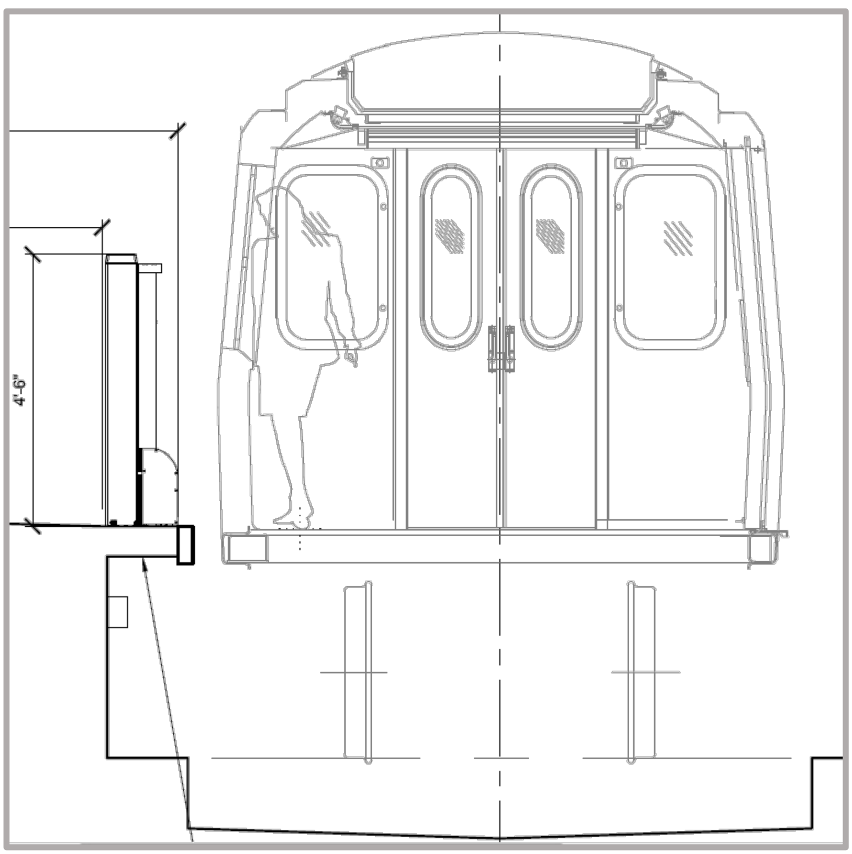


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 $lbs/ft.^2$ (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

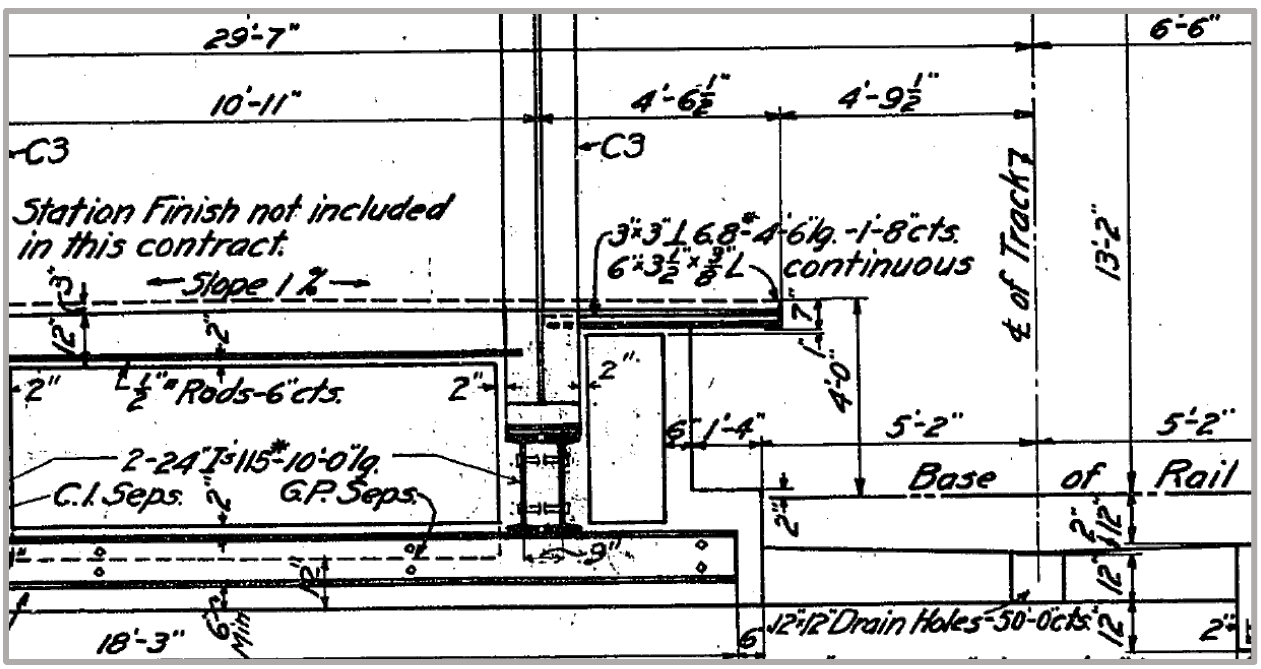

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

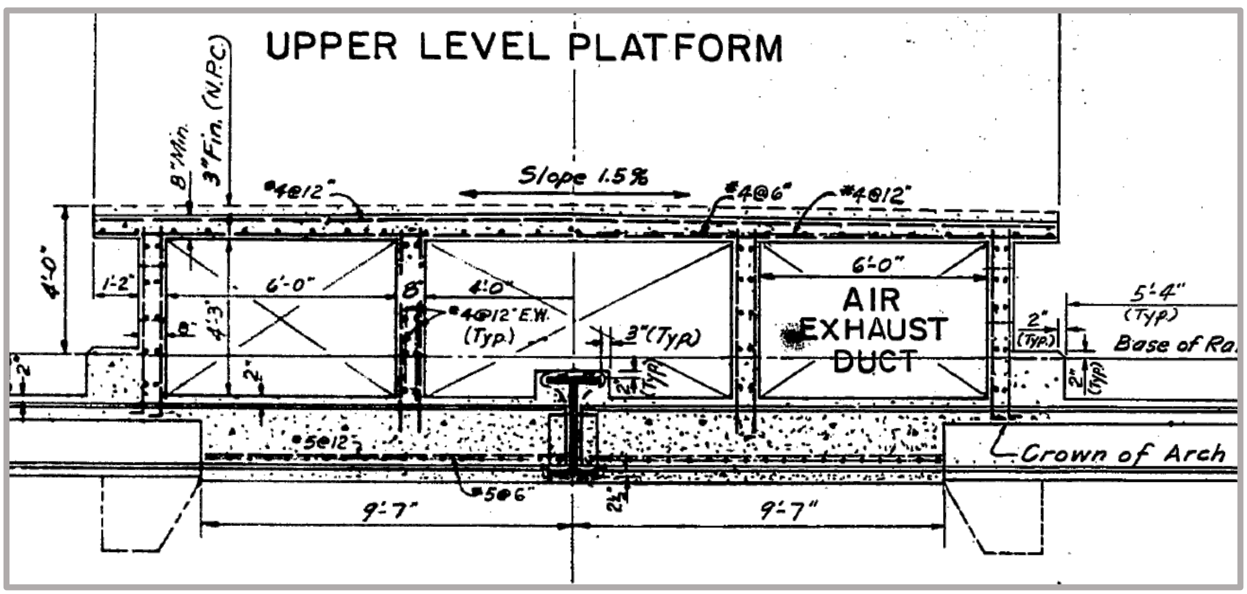

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

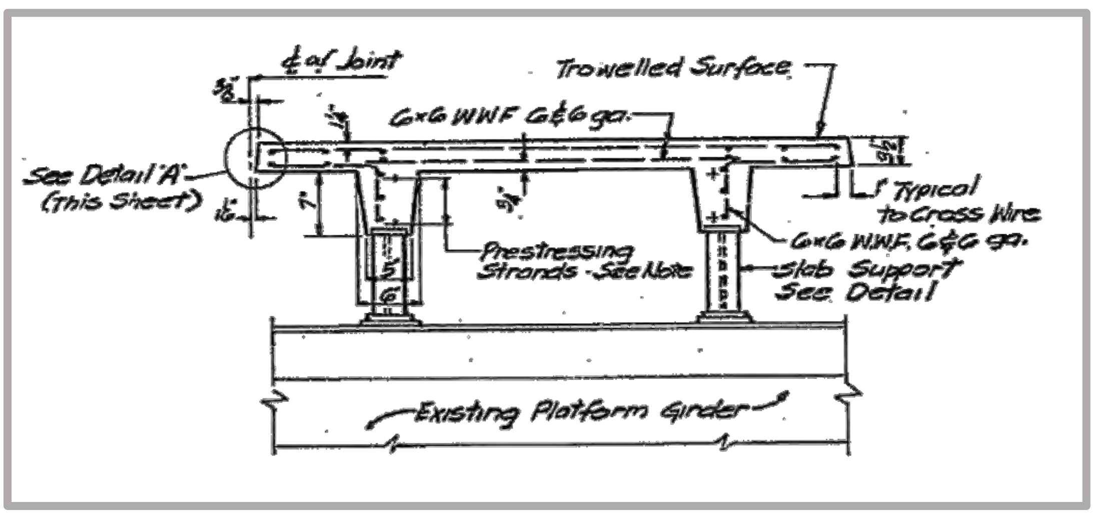

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

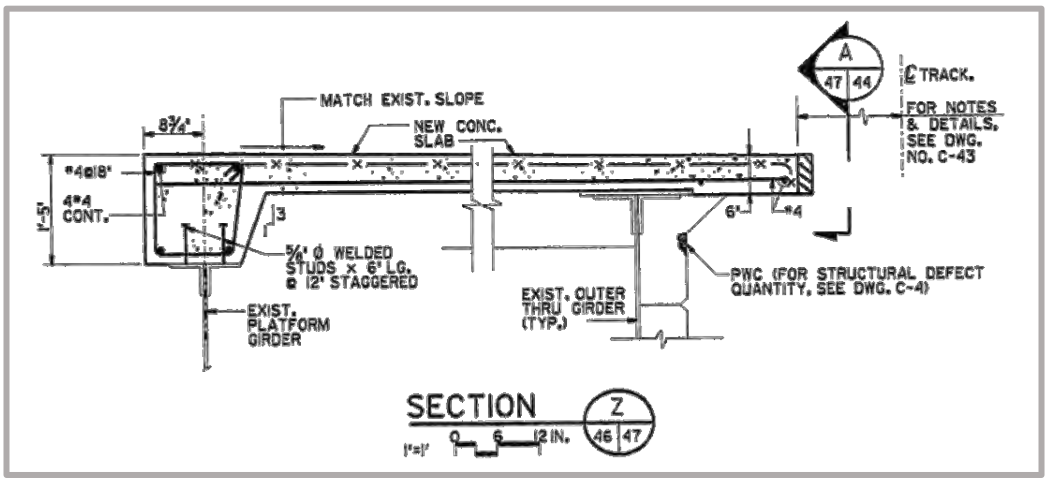

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

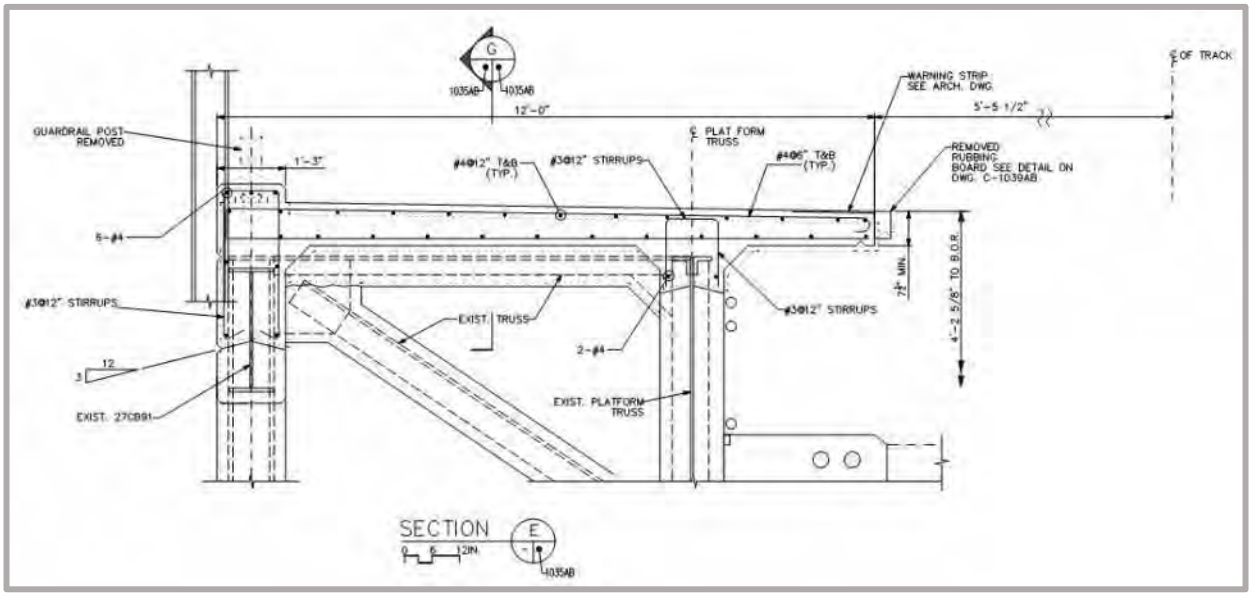

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3" thick structural slab with an approximately 3" thick topping slab. If the topping slab is fully removed, a 6" thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6" thick slab will be sufficient for a cantilever length of up to approximately 3'-0", greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6" structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6" minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

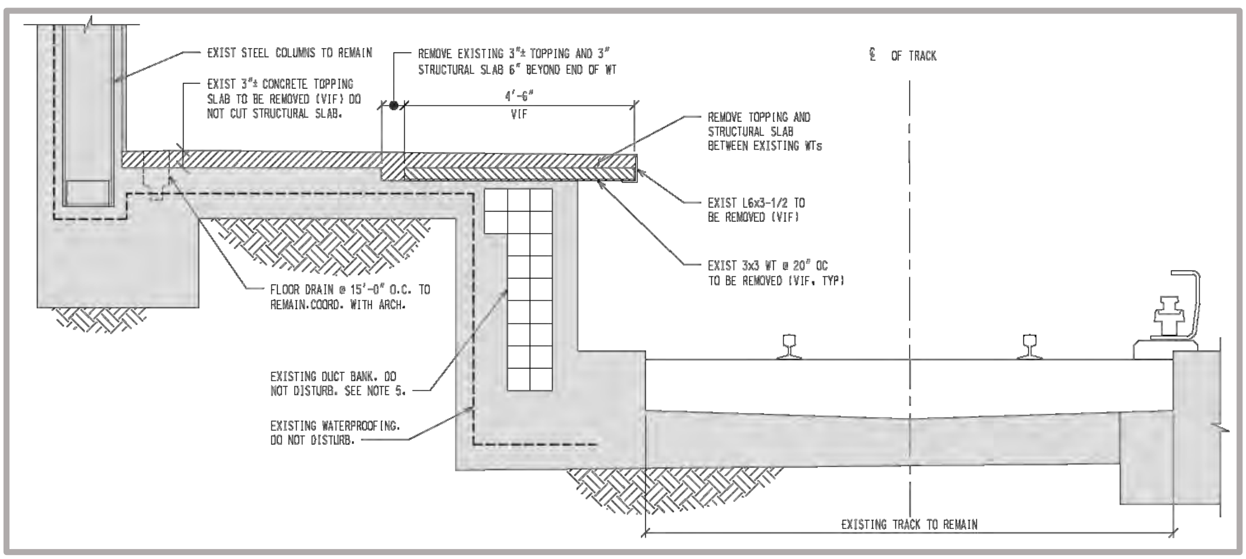

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

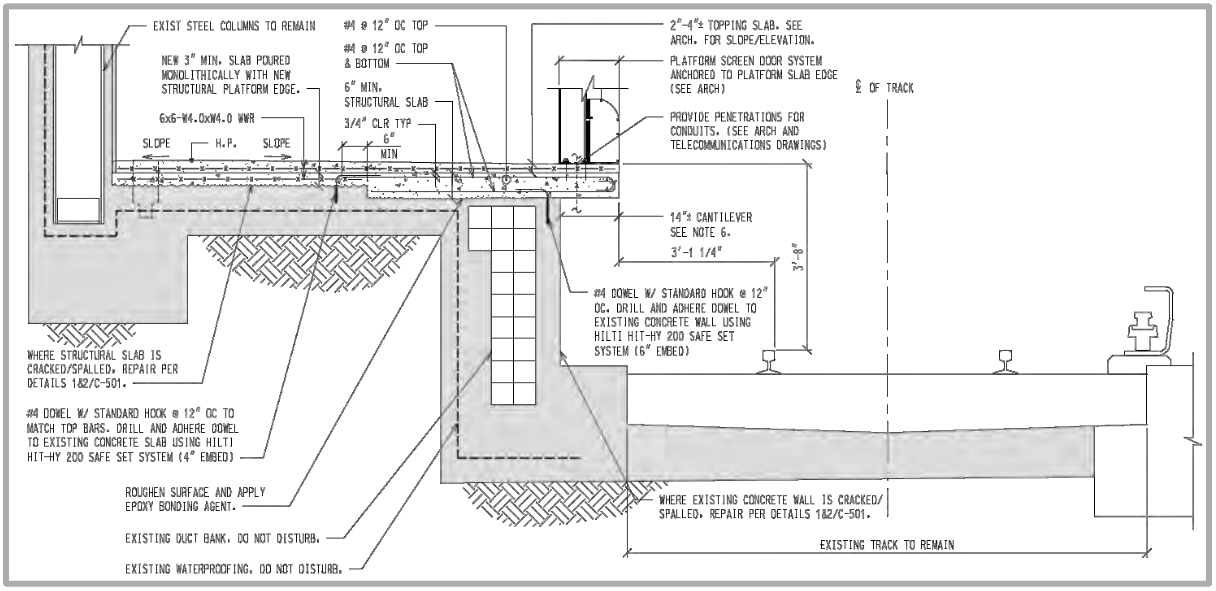

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

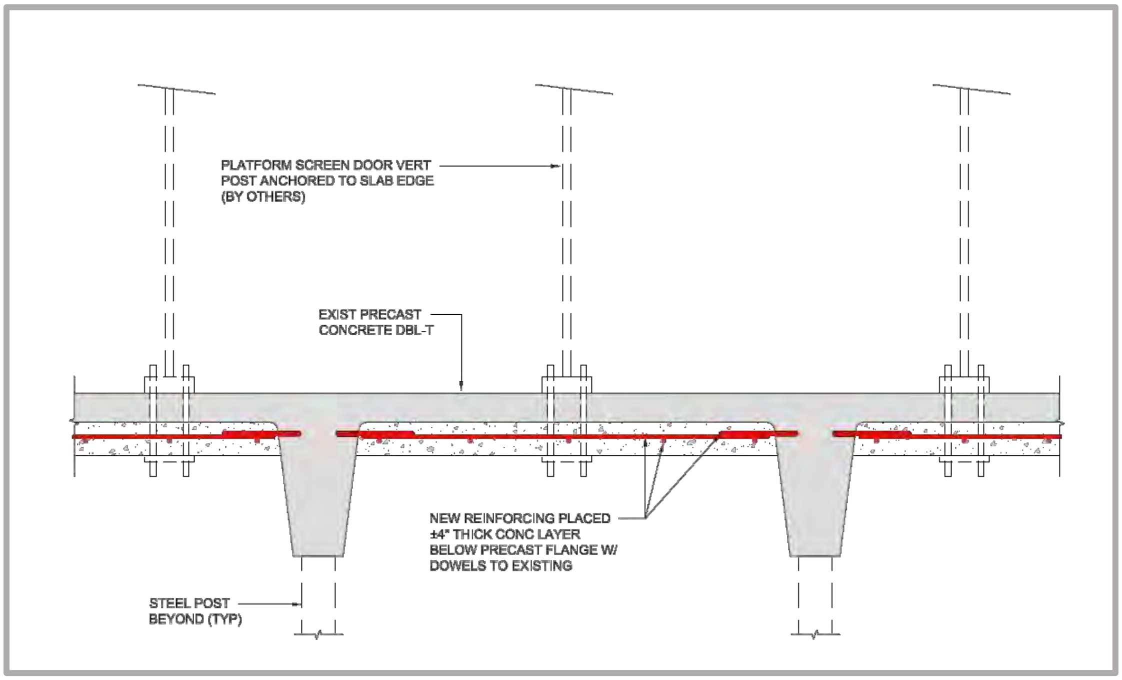

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5’ – 11” of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

MTA/NYCT

August 8, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

MTA/NYCT

August 8, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

8-Aug-19

STATION : STERLING STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	507	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	507	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,014**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,014	LF	7	7,098
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,070	SF	12	60,840
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	102	CY	2,500	255,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,016	EA	25	25,400
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,016	EA	25	25,400
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,014	LF	95	96,330
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,014	LF	15	15,210
26	Remove existing platform tiles	1,014	LF	12	12,168
27	Sawcut existing topping concrete at perimeter of removal area	1,014	LF	5	5,070
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,084	SF	8	48,672
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 12'-0" wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,014	SF	15	15,210

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

8-Aug-19

STATION : STERLING STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	480	SF	15	7,200
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	360	LF	110	39,600
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing mezzanine slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 3 Doors = 30 No. per platform)	60	EA	15,000	900,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #29 per Platform	58	EA	10,500	609,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,088	SF	750	1,566,000
61	Spare Parts - Approx. 10% of Material Cost	1	LS	190,020	190,020
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	60	EA	2,500	150,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

8-Aug-19

STATION : STERLING STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
71	Allow for conduit / cable runs for power and communications under platform edge	1,014	LF	60	60,840
72	PSD Connections	1	LS	75,000	75,000
73	Allowance for Electrical / Comms Work inside Control Room including Panels, etc.	1	EA	200,000	200,000
74	Power to PSD Room from EDR [Conduit & Cable]	100	LF	60	6,000
75	Reserve power to PSD Room from EDR [Conduit & Cable]	150	LF	60	9,000
76	No allowance for new lighting as if APG's are used		Note		EXCL.
77	Grounding				
78	Allowance for new grounding wiring for structural steel and new sensors throughout station	1	EA	25,000	25,000
79	MISC				
80	Testing and commissioning	1	EA	30,000	30,000
81	As Built, Shop Drwgs, Permits and approvals	1	LS	30,000	30,000
82					
83	**Communications**				
84	FA System				
85	Scope in connection with Fire Alarm System	1	LS	100,000	100,000
86	CCTV coverage				
87	CCTV Camera System [#1 per Door & additional #1 per Car]; including access nodes, panels, wiring, conduit, etc.	80	EA	12,000	960,000
88	CCTV Network Rack (w/ IE-5000, Fire Wall, Server, KVM, Net guard, PDU), Application Fiber Distribution Panel (AFDP)	1	LS	100,000	100,000
89	Berthing Technology Sensors				
90	Allowance for Berthing Technology for Control Train Berthing including software and hardware requirements	10	EA	16,000	160,000
91	Train Door Detection System				
92	Train Door Detection Sensor including software and hardware requirements	10	EA	15,000	150,000
93	Entrapment concerns				
94	Sick LMS100-10000 laser scanner [Allowance of 3 per opening]; including specialist sub-contractor mark-up	180	EA	4,629	833,263
95	Allowance for labor in mounting to the roof, the convertor boxes, the Ethernet+power wiring and the PSD room equipment.	180	EA	5,566	1,001,802
96	Engineering and Testing	1,000	Hrs	160	159,930
97	Centralized monitoring/control				
98	Allowance for the provision of a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.	1	LS	70,000	70,000
99	MISC				
100	Penetration, patching, selective demo and minor modifications	1	LS	25,000	25,000
101	Testing and commissioning (Except Entrapment, Berthing, TDDS)	1	LS	40,000	40,000
102	Site Survey and Inspections	1	LS	100,000	100,000

8-Aug-19

STATION : FULTON STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	538	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	538	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,077**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,077	LF	7	7,538
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,384	SF	12	64,610
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	109	CY	2,500	272,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,079	EA	25	26,971
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,079	EA	25	26,971
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,077	LF	95	102,300
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,077	LF	15	16,153
26	Remove existing platform tiles	1,077	LF	12	12,922
27	Sawcut existing topping concrete at perimeter of removal area	1,077	LF	5	5,384
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,461	SF	8	51,688
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	480	SF	8	3,840
30	New Work				
31	New concrete topping to match existing	1,077	SF	15	16,153

STATION : BOWLING GREEN

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	560	SF	15	8,400
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	360	LF	110	39,600
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Platform column restructuring**				
37	Demolition				
38	Install, maintain and remove temporary support	2	LS	15,000	30,000
39	Breakout existing platform slab for new column	2	LS	5,000	10,000
40	New Work				
41	Excavate for foundation for new column	2	EA	1,500	3,000
42	Foundation for new column	2	EA	5,000	10,000
43	New structural steel column	2	EA	20,000	40,000
44	Extend and repair beams above	2	LS	5,000	10,000
45	Grillage	2	EA	10,000	20,000
46					
47	**Equipment Room [7'-0" x 27'-6"]**				
48	Build off existing platform slab		Note		
49	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
50	CMU Wall for equipment room	415	SF	45	18,675
51	Vertical connections with existing structure	20	LF	25	500
52	Roof for equipment room	193	SF	30	5,775
53	Fire rated door including frame & hardware	1	EA	2,500	2,500
54	Exterior wall finish				
55	Ceramic Tiling to match existing	415	SF	40	16,600
56	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
57	Concrete cove to match existing	42	LF	20	830
58	Interior Wall Finish - Paint	690	SF	5	3,450
59	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
60	Allow for 4" thick concrete pads for equipment	48	SF	20	963
61	Allowance for Mechanical Scope	1	LS	40,000	40,000
62	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
63	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
64	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
65					
66	**Automatic Platform Gates [APGs] - 4'-6" High**				
67	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 3 Doors = 30 No. per platform)	60	EA	15,000	900,000
68	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #29 per Platform	58	EA	10,500	609,000
69	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
70	Platform End Gates (PEGs)	4	EA	13,000	52,000
71	Fixed Panels including framing and support; 4'-6" High	2,196	SF	750	1,647,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

8-Aug-19

STATION : BAYCHESTER AVENUE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	525	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	526	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,051**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,051	LF	7	7,355
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,253	SF	12	63,041
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	106	CY	2,500	265,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,053	EA	25	26,317
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,053	EA	25	26,317
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,051	LF	95	99,815
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,051	LF	15	15,760
26	Remove existing platform tiles	1,051	LF	12	12,608
27	Sawcut existing topping concrete at perimeter of removal area	1,051	LF	5	5,253
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,304	SF	8	50,433
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	520	SF	8	4,160
30	New Work				
31	New concrete topping to match existing	1,051	SF	15	15,760

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-5 Line Stations

8-Aug-19

STATION : MORRIS PARK

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	523	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	523	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,046**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR '6' SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: April 12, 2019

STV 100 Years

Table of Contents

Appendices
Appendix A: Tier 2-3 Technology Assessment
Appendix B: Structural Feasibility Report
Appendix C: Emergency Egress Width Analysis
Appendix D: Maintenance Cost Estimate
Appendix E: Rough Order of Magnitude Costs

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 38 newly evaluated stations, 33 have been found to be not suitable for the installation of PSDs.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at all of the 6-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 13% of the '6' Line Stations. Total implementation cost would be $136.6M for APGs and $172.3M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 5 feasible stations, the aggregate annual maintenance cost would be $4.6M.

1.0 Station Assessments

1.01 – MR 360 | Pelham Bay Park Station

Summary: *Pelham Bay Park Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Pelham Bay Park Station is an elevated station with one island platform. The platform structures is precast concrete. The width of the platforms is approximately 15'-0" throughout. The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Pelham Bay Parkway Station

Figure 2 *– Precast Slab*
Pelham Bay Parkway Station

1.02 – MR 361 | Buhre Avenue Station

Summary: *Buhre Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Buhre Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 12'-0" to 13'-8". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Buhre Avenue Westchester Avenue Station

Figure 2 *– Precast Slab*
Buhre Avenue Westchester Avenue Station

1.03 – MR 362 | Middletown Road Station

Summary: *Middletown Road Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Middletown Road Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11-2" to 12'-0". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

***Figure 1** – General Station Condition*
Middletown Road Station

***Figure 2** – Precast Slab*
Middletown Road Station

1.04 – MR 363 | Westchester Square East Tremont Ave Station

Summary: *Westchester Square East Tremont Ave.Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Westchester Square East Tremont Ave. Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 12'-0" to 14'-10". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Westchester Square East Tremont Station

Figure 2 *– Precast Slab*
Westchester Square East Tremont Station

1.05 – MR 364 | Zerega Avenue Station

Summary: *Zerega Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Zerega Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-10" to 11'-2". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Figure 1 *– General Station Condition*
Zerega Avenue Station

Figure 2 *– Precast Slab*
Zerega Avenue Station

1.06 – MR 365 | Castle Hill Avenue Station

Summary: *Castle Hill Avenue Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Castle Hill Avenue Station is an elevated station with two side platforms. The platform structures are precast concrete. The width of the platforms varies from approximately 11'-10" to 12'-0". The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

1.07 – MR 366 | Parkchester Station

Summary: *Parkchester Station is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see Appendix B).*

Description

The Parkchester Station is an elevated station with two center / island platforms. The platform structures are precast concrete. The width of the platforms are approximately 16'-6" throughout. The platforms are straight with one row of columns supporting their respective station canopies See figure 1 & 2 for reference.

Table of Contents

1.12 – MR 371 | Hunts Point Avenue Station

Summary: *Hunts Point Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The Hunts Point Avenue Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The corridor width at the southern end of the southbound platform is 3'-10". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Hunts Point Avenue Station

1.13 – MR 372 | Longwood Avenue Station

Summary: *Longwood Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The Longwood Avenue Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The corridor width at the southern end of the southbound platform is 3'-4". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – *Area of ADA non-compliance*
Longwood Avenue Station

1.14 – MR 373 | East 149th Street Station

Summary: *East 149th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity is adequate.*

Description

East 149th Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout most of the length of the platforms. Column faces measure approximately 4'-2" from the platform edge. The platform widths are approximately 12-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the northbound control area (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are mildly curved. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the last thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would be required for the installation of an APG system.

Table of Contents

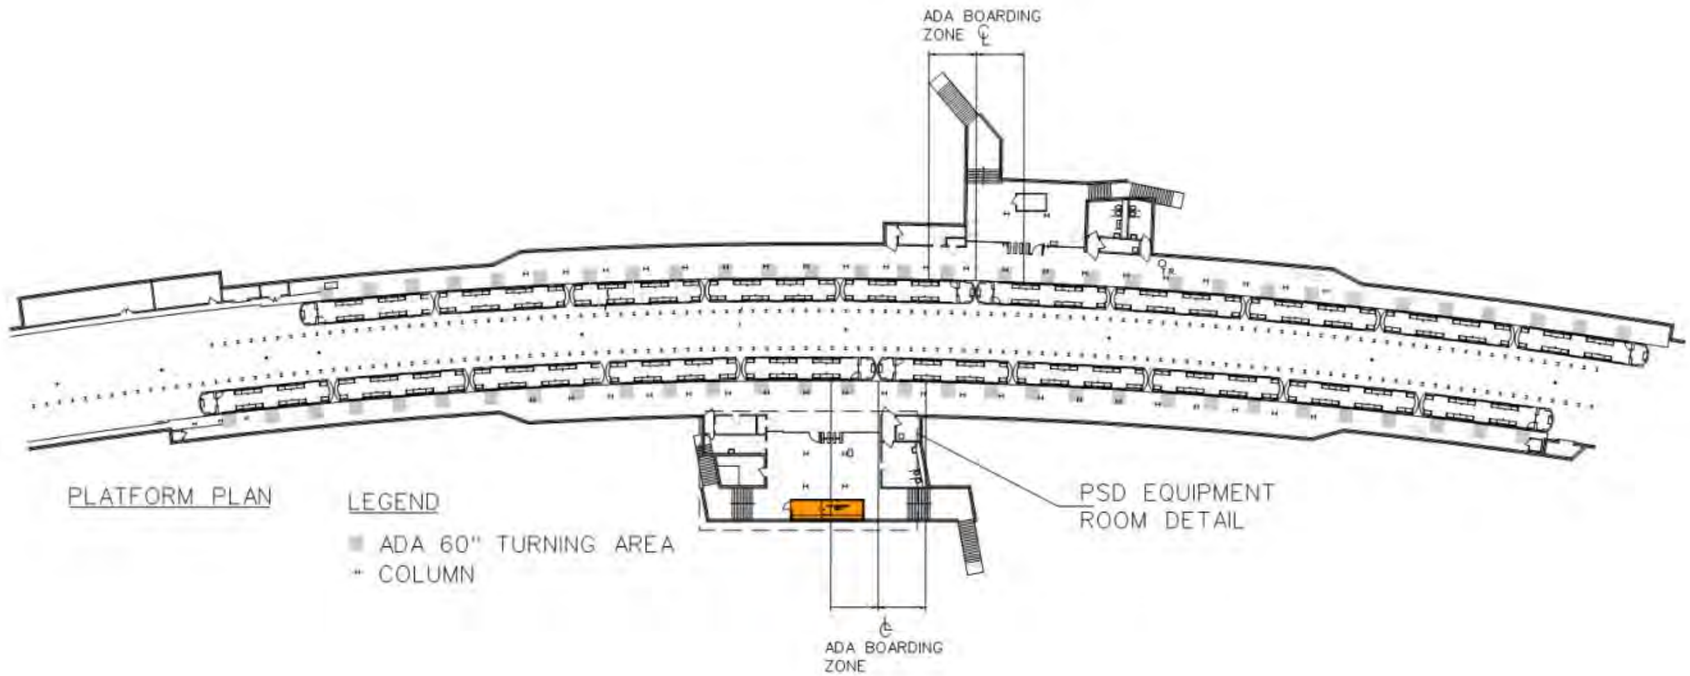

***Figure 1** – Overall Station Plan*
East 149th Street Station

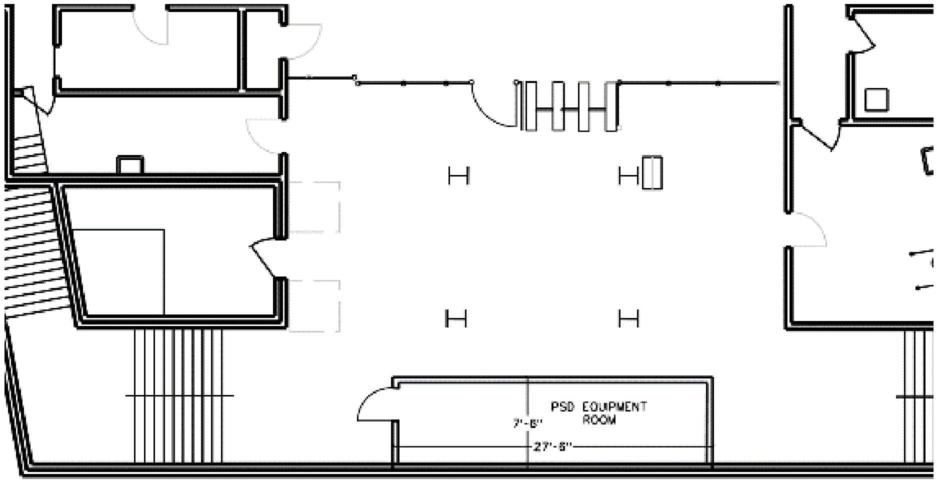

Figure 2 *– PSD Equipment Room 1 Detail*
East 149th Street Station

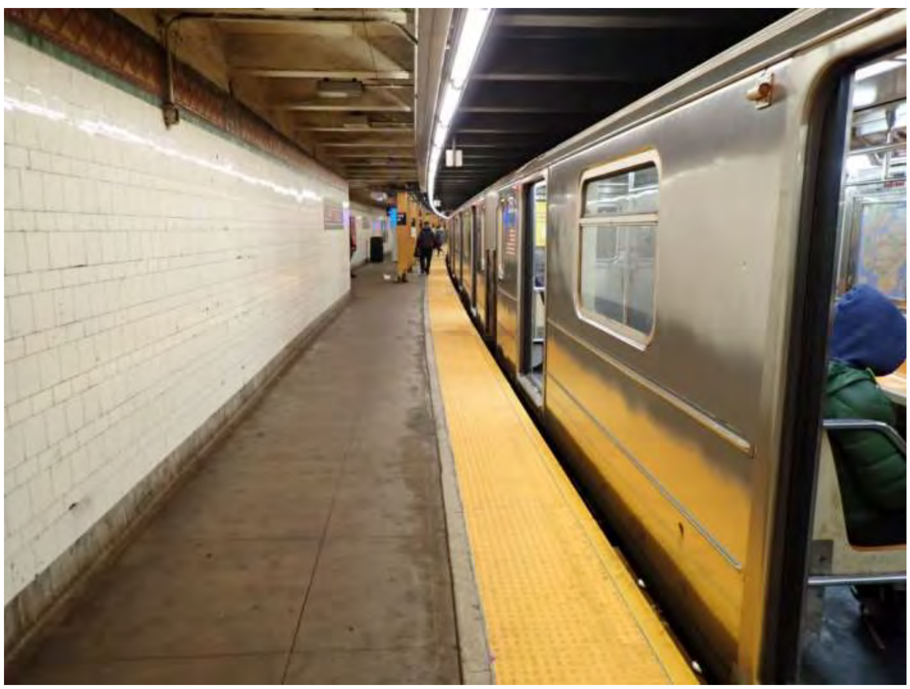

Figure 3 *– Typical platform view*
East 149th Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 & 2 see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)	
Station Name	East 149th Street
Peak Demand Load from ConEd Report, (kW)	39.2
Apparent Power (kVA)	49.0
Station Peak Demand Load, Max Current, (A)	136.1
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	294.2
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	506
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 800 A Service switch. Station has (2) separate meter readings for each Normal & Reserve service.

Table 1. Normal Service Power Capacity Analysis

Station Power Capacity Analysis (Reserve Service)	
Station Name	East 149th Street
Peak Demand Load from ConEd Report, (kW)	13.6
Apparent Power (kVA)	17.0
Station Peak Demand Load, Max Current, (A)	47.2
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	205
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	595
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 800 A Service switch. Station has (2) separate meter readings for each Normal & Reserve service.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.2M to install APGs and $34.2M to install PSDs (See Appendix E)

1.15 – MR 374 | East 143rd Street – Saint Mary's Station

***Summary:** East 143rd Street Station is not feasible for both APGs and PSDs due to lack of available space for the PSD equipment room.*

Description

East 143rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. There is a single row of columns on each platform.

Due to the limited width of the existing platforms, there is no available space for the equipment room. Figure 2 below shows the minimum width required (12'-11") for construction of a PSD equipment room on a station platform. Figure 1, below, demonstrates the lack of available space within the control area.

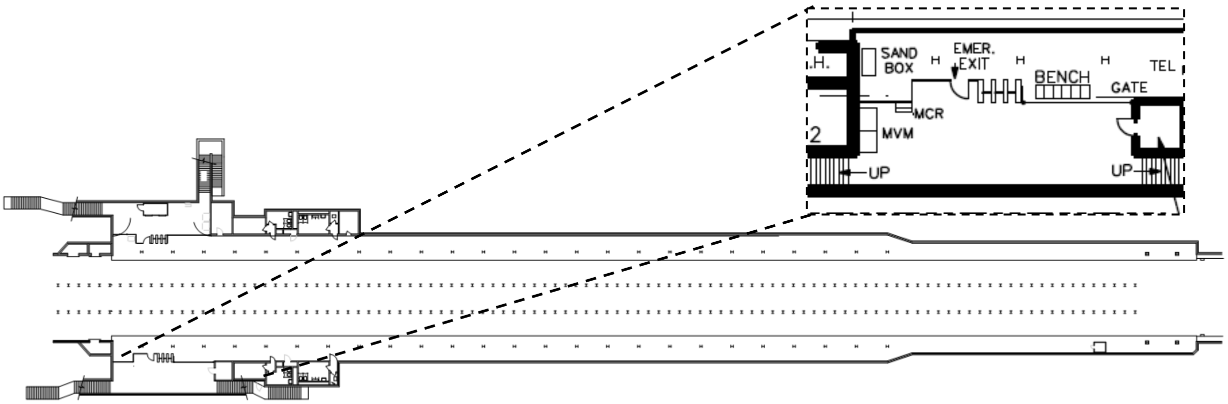

***Figure 1** – Congested/Narrow Station Plan*
East 143rd Street Station

Table of Contents

1.17 – MR 376 | Brook Avenue Station

Summary: *Brook Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity is adequate.*

Description

Brook Avenue Station is a below-grade station with two straight side platforms (**see Figure 1**). The platform structures are cast-in-place concrete. Columns are located through the central third of the platforms along the platform edge. The platform widths vary from approximately 7'-10" to 11-10". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the northbound control area (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would be required for the installation of both an APG and PSD system.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)	
Station Name	Brook Avenue
Peak Demand Load from ConEd Report, (kW)	55.2
Apparent Power (kVA)	69.0
Station Peak Demand Load, Max Current, (A)	191.7
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	349.8
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	450
Is Electrical Service Adequate?	Peak Demand Load from ConEd Report, (kW)
Notes	Service rating is based on field survey and 1 line diagram, having 800 A Service switch. Station has (2) separate meter readings for each Normal & Reserve service.

***Table 1**. Normal Service Power Capacity Analysis*.

Station Power Capacity Analysis (Reserve Service)	
Station Name	Brook Avenue
Peak Demand Load from ConEd Report, (kW)	1.6
Apparent Power (kVA)	2.0
Station Peak Demand Load, Max Current, (A)	5.5
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	164
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	636
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 800 A Service switch. Station has (2) separate meter readings for each Normal & Reserve service.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.1M to install APGs and $34.0M to install PSDs (See Appendix E)

1.18 – MR 377 | 3rd Avenue- 138th Street Station

Summary: *3rd Avenue -138th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 27" (see figure 1).*

Description

The 3rd Avenue -138th Street Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-0' to 17'-10". At the south end of the northbound platform, the width is 4'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 27" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
3rd Avenue -138th Street Station

1.19 – MR 392 | 125th Street

Summary: *125th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1). In addition, the station is infeasible due to the presence of columns near the platform edge (see figure 2).*

Description

125th Street Station is a below-grade station with two levels of straight center / island platforms. The no. 6 train utilizes both the upper and lower level. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 29'-8". At the lower platform, the implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

The upper platform is infeasible for both APGs and PSDs due to the presence of structural columns on the platform which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 2 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

1.22 – MR 395 | 103rd Street

Summary: *103rd Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

103rd Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platforms. The platform widths are approximately 7-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the mezzanine control area of the station (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Platform obstructions within 5' of edge:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted perpendicular to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station
Power Capacity Analysis (Normal service)

Station Name	103rd Street
Peak Demand Load from ConEd Report, (kW)	26.8
Apparent Power (kVA)	33.5
Station Peak Demand Load, Max Current, (A)	93.1
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	251.2
Station Service Power Capacity, (Main SB or SG Rating), (A)	400.0
Service Spare Capacity, (A)	148.9
Is Electrical Service Adequate?	**Yes**
Notes	Service rating of 400A is based on field observations. Station has only (1) meter readings for Normal service. The station Reserve meter was NOT accessible during field survey. (No meter in Reserve EDR) 1 Line diagram provided is not current.

Table 1. Normal Service Power Capacity Analysis

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.6M to install APGs and $34.5M to install PSDs (See Appendix E)

1.23 – MR 396 | 96th Street

Summary: *96th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 5'-0" (see figure 1).*

Description

96th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 5'-0' to 12'-10".

The platform width at the end of the southbound platform is 5'-0" or 60". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

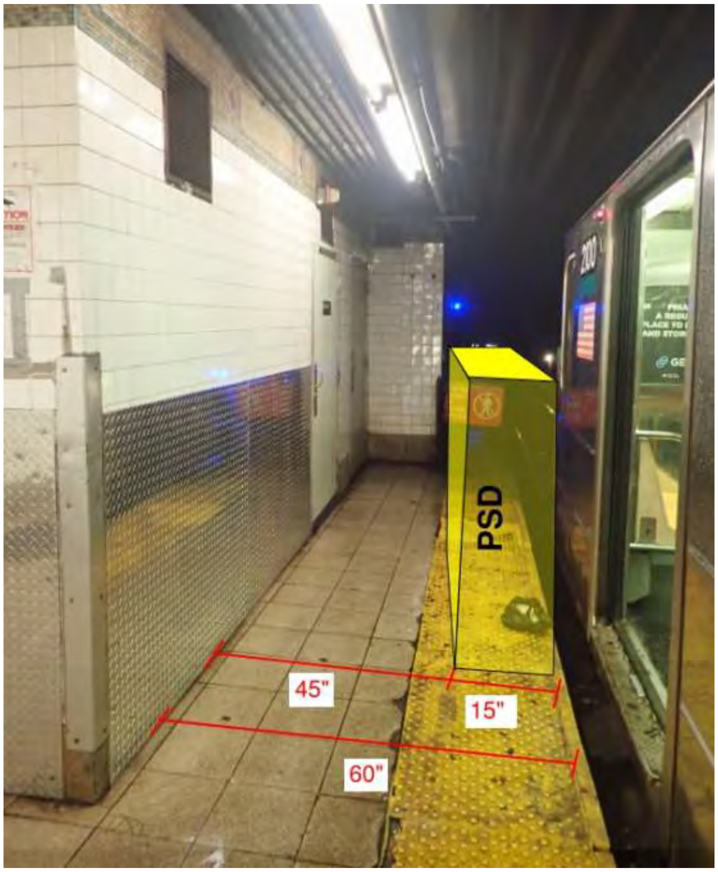

***Figure 1** – Non-Compliant egress condition*
96th Street Station

Table of Contents

1.24 – MR 397 | 86th Street

Summary: *86th Street is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the center stairs as the remaining width would be 31" (see figure 1).*

Description

The 86th Street Station is a below-grade station consisting of two side platforms on two levels. The No. 6 service normally runs at the upper level. At the upper level, the platforms are approximately 13'-8" wide. The platforms are straight with one row of columns at 46" from the edge of the platform. The implementation of a platform edge barrier would reduce this width at the staircase to 31" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA dimension*
86th Street Station- upper level

1.25 – MR 398 | 77th Street

Summary: *77th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

The 77th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-8". The implementation of a platform edge barrier would reduce the lesser width below the required minimum of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA condition*
77th Street Station

Table of Contents

1.26 – MR 399 | 68th Street Hunter College

Summary: *68th Street Hunter College Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of both platforms as the existing width is 4'-2" (see figure 1).*

Description

68th Street Hunter College Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-2' to 11'-10".

Platform width at the southbound end of the northbound & southbound platform is 4'-2" or 50". Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

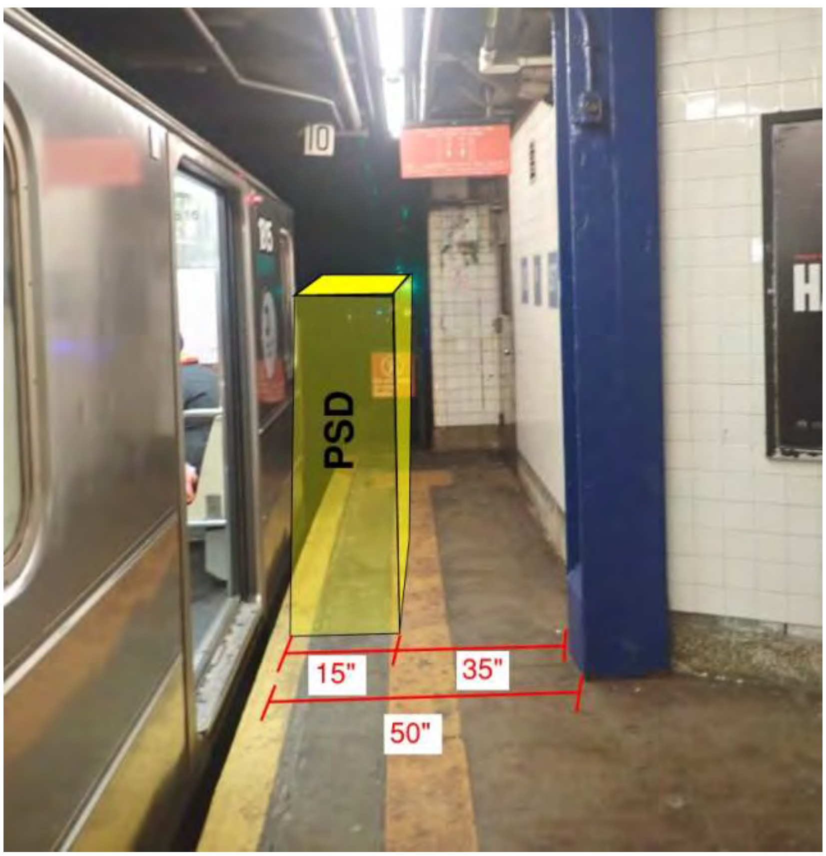

***Figure 1** – Non-Compliant egress condition*
68th Street Hunter College Station

1.27 – MR 400 | 59th Street Station

Summary: *59th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

59th Street Station is a below ground station with two side platforms on two levels. The No.6 line runs normally on the upper level (**see Figure 1**).. The platform structures are cast-in-place concrete. There is one row of columns located at 3'-10" from the platform edge. The platform widths range from 7-10" to 23'-2". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located on the northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for '6' Line Stations
(59th Street Station)

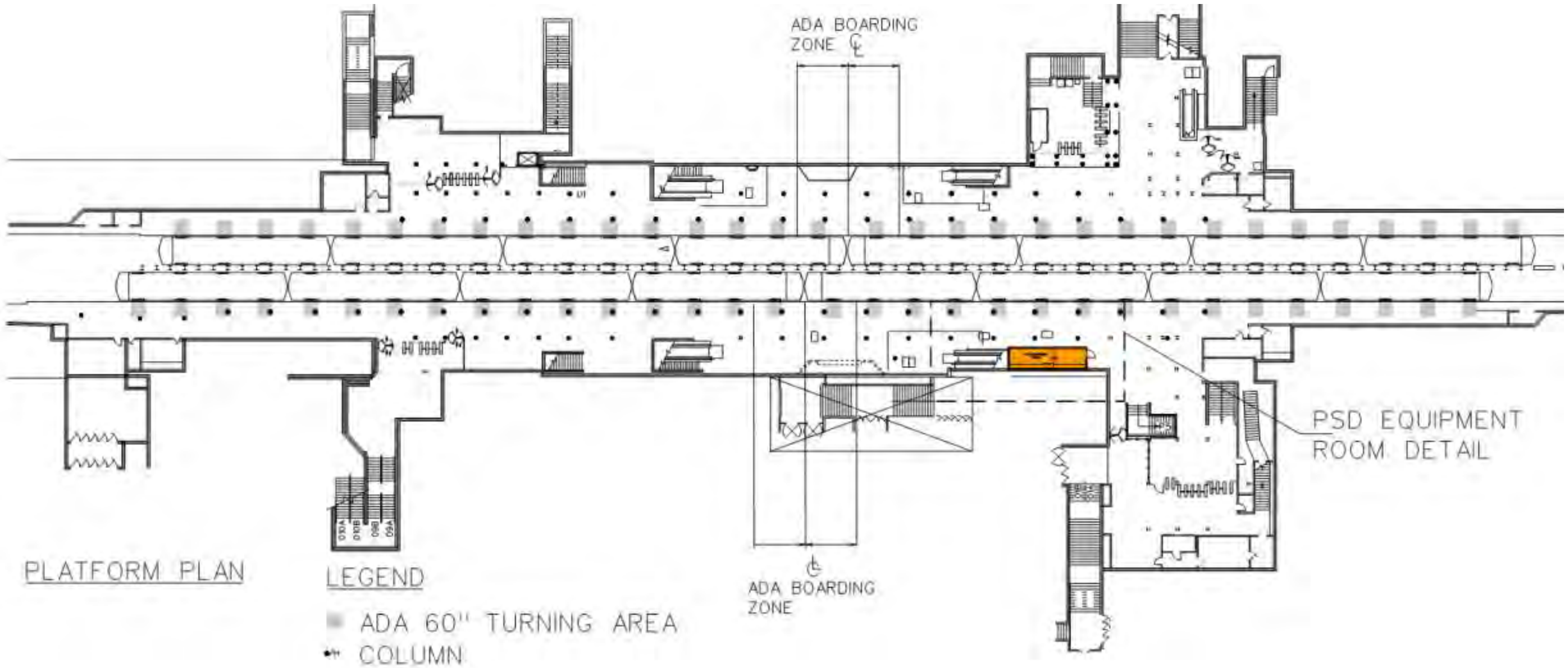

Figure 1 *– Overall Station Plan*
59th Street Station

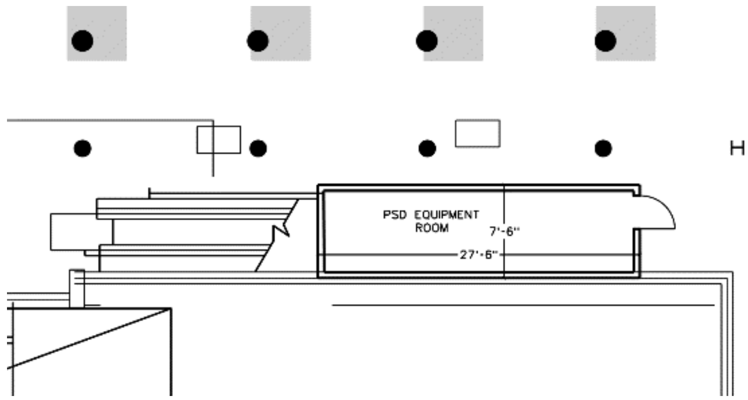

***Figure 2** – PSD Equipment Room Detail*
59th Street Station

***Figure 3** – Typical platform view*
59th Street Station

Platform obstructions within 5' of edge:

- Columns

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration

Power:

This station has adequate electrical capacity to support the implementation of an APG/PSD system. An analysis of electrical reserve service could not be performed due to inaccessibility during survey. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Table 1 see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)	
Station Name	59th Street
Peak Demand Load from ConEd Report, (kW)	65.6
Apparent Power (kVA)	82.0
Station Peak Demand Load, Max Current, (A)	227.8
Maximum Amount of Doors	60.0
PSD Total Load Including All Miscellaneous Loads, (A)	158.1
Total Load (Station Peak + PSD), (A)	385.9
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	814
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on field survey and 1 line diagram, having 1200 A Service switch. Station has only one meter readings provided for Normal service. No reserve meter reading provided.This analysis is for **Normal service**. No meter in Reserve EDR, but it is in Elevator Machine room and was not accesible during field survey.

Table 1. *Normal Service Power Capacity Analysis*

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $27.3M to install APGs and $35.1M to install PSDs (See Appendix E)

1.28 – MR 401 | 51st Street

Summary: *51st Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

51st Street Station is a below-grade station with two side platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are located throughout the platforms along the platform edge. Column faces measure approximately 3'-8" from the platform edge. The platform widths are approximately 11-4" to 20'-0". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be \$27.3M to install APGs and \$34.4M to install PSDs (See Appendix E)

Table of Contents

1.29 – MR 402 | 42nd Street Grand Central

Summary: *42nd Street Grand Central Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

The 42nd Street Grand Central Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-10' to 24'-0". The implementation of a platform edge barrier would reduce this width below the required minimum of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

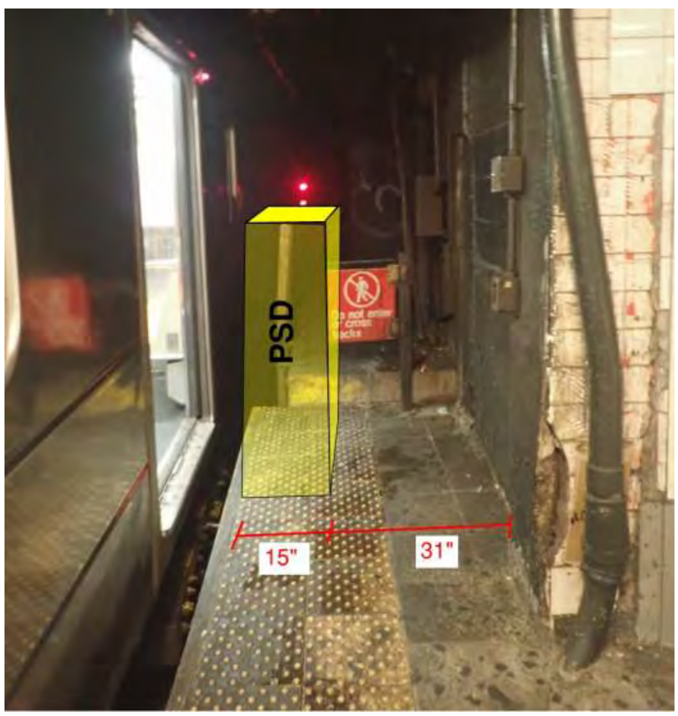

***Figure 1** – Non-compliant ADA condition*
42nd Street Grand Central Station

Table of Contents

1.30 – MR 403 | 33rd Street

Summary: *33rd Street Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

33rd Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
33rd Street Station

1.31 – MR 404 | 28th Street

Summary: *28th Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

28th Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The column pictured in Figure 1 measures approximately 14" from the platform edge. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 14" from the edge*
28th Street Station

1.32 – MR 405 | 23rd Street

Summary: *23rd Street Station is not feasible for both APGs and PSDs as the columns which are located 14" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

23rd Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 14" from the platform edge. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 14" from the edge*
23rd Street Station

1.33 – MR 406 | 14th Street- Union Square

Summary: *14th Union Square Station is not feasible for both APGs and PSDs due to the presence of platform edge gap fillers located at all southbound platform edges. The existing gap fillers are a dynamic assembly that extends the platform edge when a train arrives, and recedes when the train departs. This moving assembly prevents the installation of a static PSD system. Please see figure 1 for reference.*

Description:

Due to the sharp curvature of the platforms at 14th Street Union Square, platform edge gap fillers are necessary to bridge the gap between the train doors and the platform edge.

Figure 1 –*Platform Edge Gap Fillers*
14th Street Union Square Station

Table of Contents

1.34 – MR 407 | Astor Place 4th Avenue

Summary: *Astor Place Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 15" (see figure 1).*

Description

The Astor Place Station is a below-grade station with two curved side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 2'-6' to 10'-8". The implementation of a platform edge barrier would reduce this lesser width below the required minimum of 32". The remaining 15" or less* would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-compliant ADA condition*
Astor Place Station

1.35 – MR 408 | Bleeker St.-Broadway / Lafayette

Summary: *Bleeker St. Station is not feasible for both APGs and PSDs as the columns which are located 18" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Bleeker Street Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 18" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 18" from the edge*
Bleeker St. Broadway Lafayette Station

1.36 – MR 409 | Spring St.

Summary: *Spring St. Station is not feasible for both APGs and PSDs as the columns which are located 22" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Spring St. Station is a below-grade station consisting of two side platforms. It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 22" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Table of Contents

1.37 – MR 410 | Canal Street

Summary: *Canal Street Station is not feasible for both APGs and PSDs as the columns which are located 16" from the platform edge would impede both access for maintenance and the ability to egress the train through the hinged emergency exit doors.*

Description:

Canal Street Station is a below-grade station consisting of two side platforms (this report covers only the Lexington IRT line). It is not feasible for both APGs and PSDs due to the presence of structural columns on the platforms which are within the envelope that the proposed PSD system(s) would occupy. The columns pictured in Figure 1 measure approximately 16" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space. Furthermore, egress doors installed on an APG/PSD system would be obstructed by the present columns. Altering the proposed APG/PSD system to adapt to the existing conditions or relocating the present structural columns pose cost prohibitive scenarios.

Figure 1 – *Column 16" from the edge*
Canal Street Station

1.38 – MR 411 | Brooklyn Bridge City Hall

Summary: *Brooklyn Bridge City Hall Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met at the center stairs as the remaining width would be 17" (see figure 1).*

Description

The Brooklyn Bridge City Hall Station is a below-grade station consisting of two center / island platforms. The platforms are approximately 15'-6" to 21'-2" wide. The platforms are mildly curved with two rows of columns at 32" from the edge of the platform. The implementation of a platform edge barrier would reduce this width to 17" or less* which would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Appendix A

Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0 and Berthing Report)

Issued: 9/15/17

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> - *a. Column location in relation to the platform edge*
> - *b. Platform edge clearance adjacent to stairs and other impediments*
> - *c. Impacts to ADA path of travel and boarding areas*
> - *d. Conflicts of PSD/APG/RPSDs with Signals cables*
> - *e. Sufficient platform width*
> - *f. Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> - *a. Structural capacity of platforms to accept PSD/APG/RPSDs*
> - *b. Feasibility & location for PSD/APG/RPSDs equipment room*
> - *c. Confirmation of adequate power for PSD/APG/RPSDs*
> - *d. Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> - *e. Determination of communications requirements, availability and cost*
> - *f. Determination of gap detection and entrapment avoidance technology requirements*
> - *g. Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.

k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.

l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

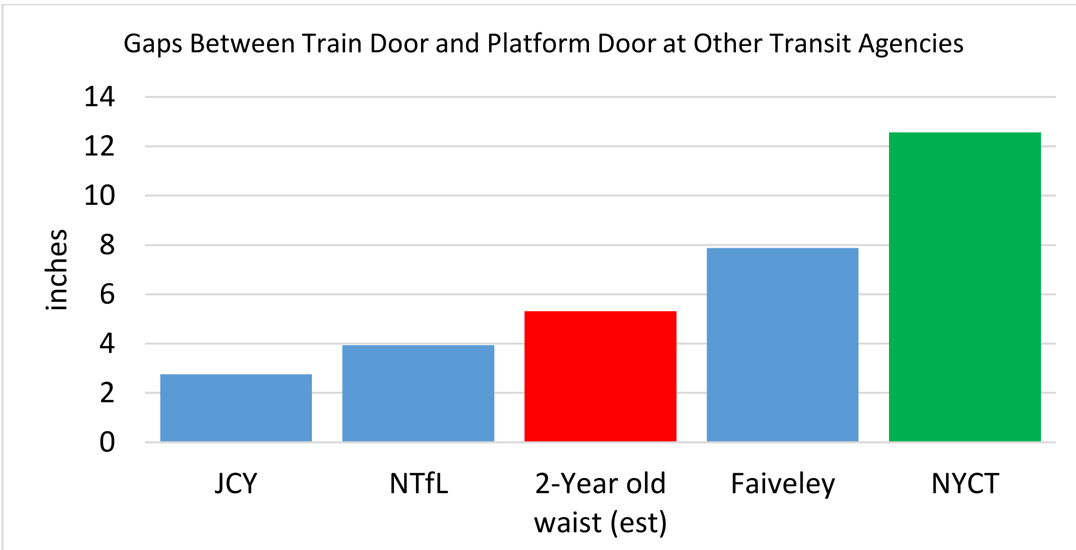

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

 *Figure 3 - Paris: no entrapment detection*	 *Figure 4 - Paris: no entrapment detection*	 *Figure 5 - France ATO: no entrapment detection*
 *Figure 6 - Paris, on curve: used 3 2D scanning lasers per door*	 *Figure 7 - Shanghai: End of platform light detection*	 *Figure 8 - Seoul: Platform observers*

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

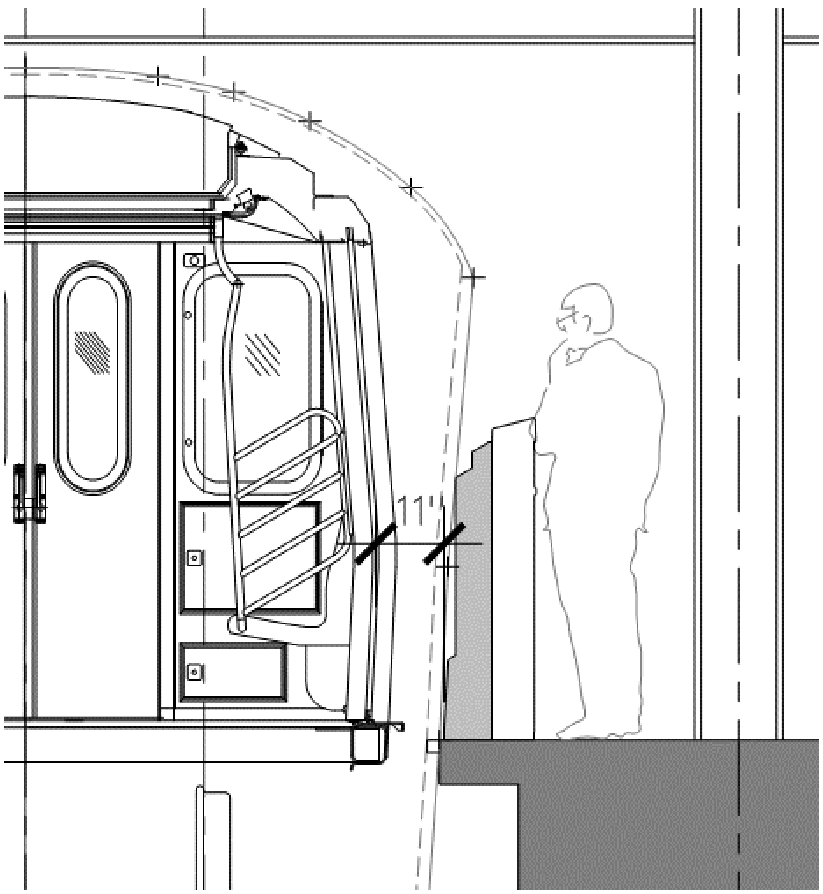

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5” by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor’s window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor’s window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **<u>In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.</u>**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **<u>When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.</u>**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **<u>When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.</u>**
- **<u>When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.</u>**
- **<u>C/R verifies that 'PSD Closed and Locked' indication is present.</u>**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **<u>Train Operator verifies that 'PSD Closed and Locked' indication is present.</u>**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **<u>and PSD/APG doors</u>** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **<u>and PSD/APG doors</u>** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **<u>of both car side doors and PSD/APG doors</u>** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	PSD System 1	PSD System 2	PSD System 3
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	**3rd Ave.**	**6th Ave.**	**14 St / Union Square**	**1st Ave.**
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are “existing” as defined by code. All the rolling stock is also to be considered “existing” under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60” radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36” of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

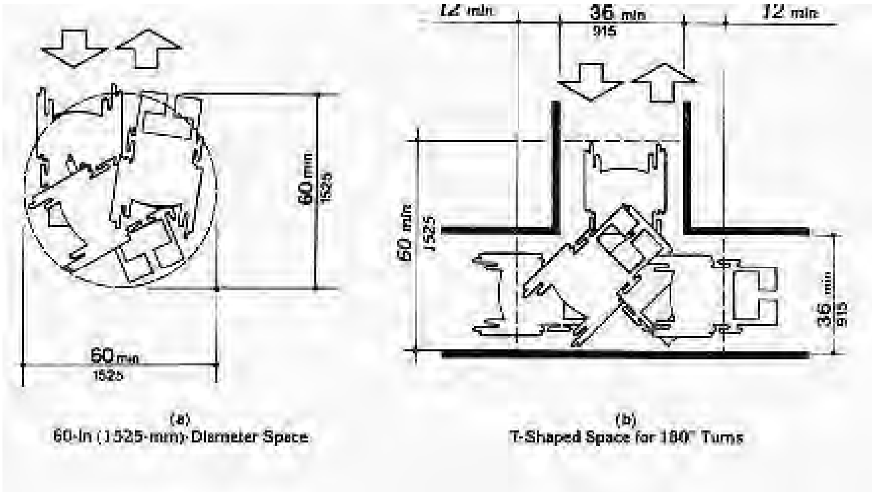
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

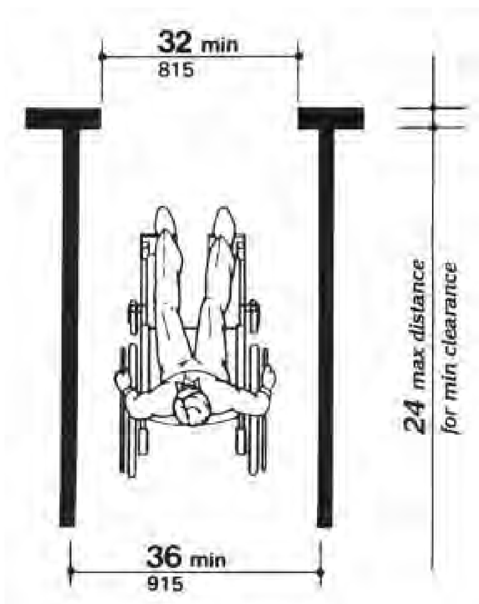


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

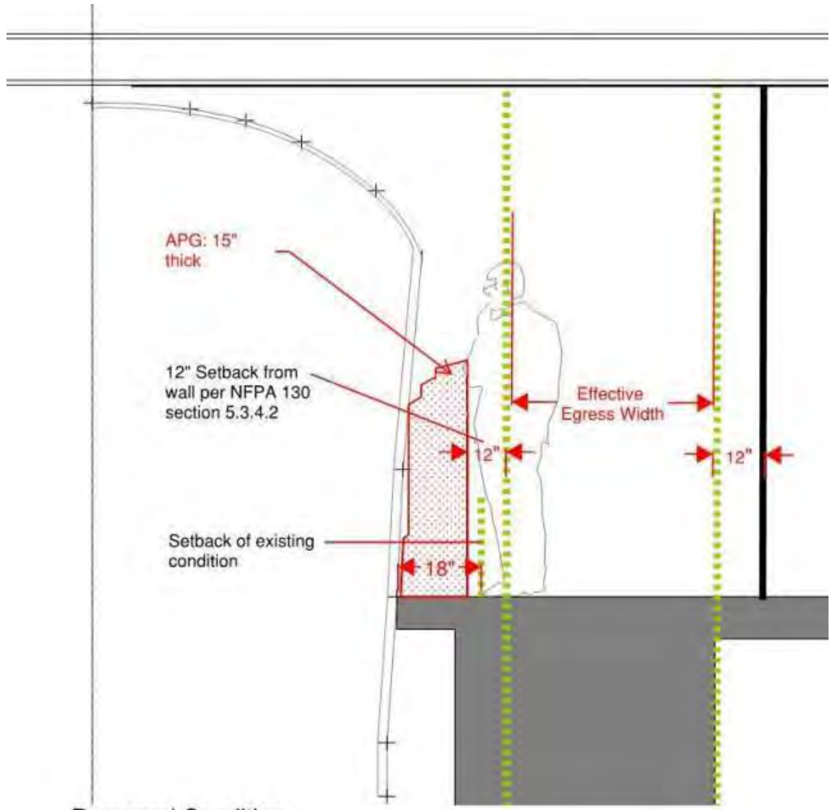
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Appendix A (Continued)

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	**Dedicated Loop**	**Wayside Only**
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	**CBTC**		**Dedicated loop**		**Wayside only**	
		Qty.	**subtotal**	**Qty.**	**subtotal**	**Qty.**	**subtotal**
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

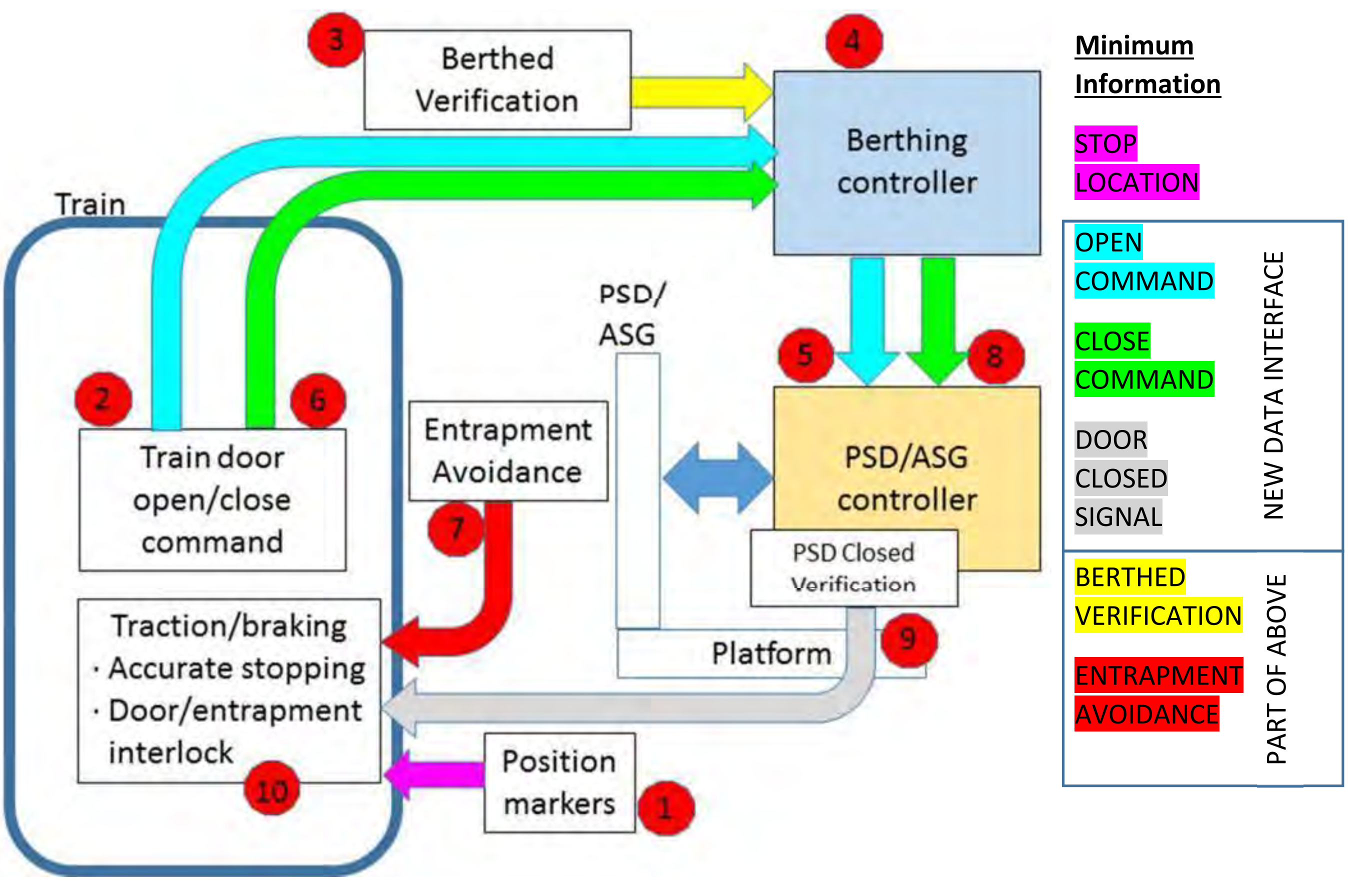
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

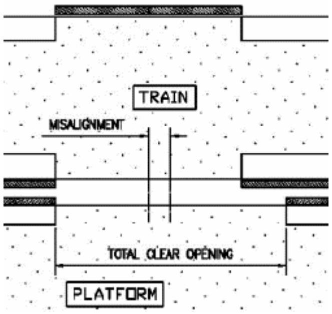
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

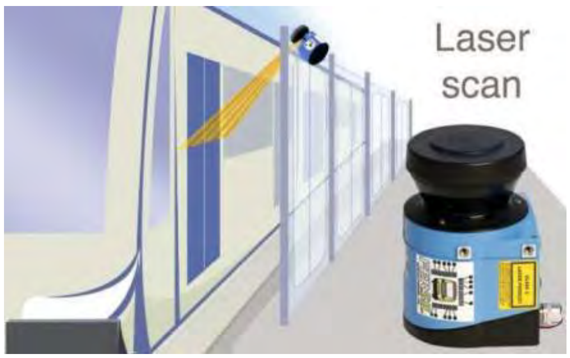
Dedicated Loop

The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically



If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.

For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B

Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

Issued: 5/9/18

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

APPENDIX B - Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

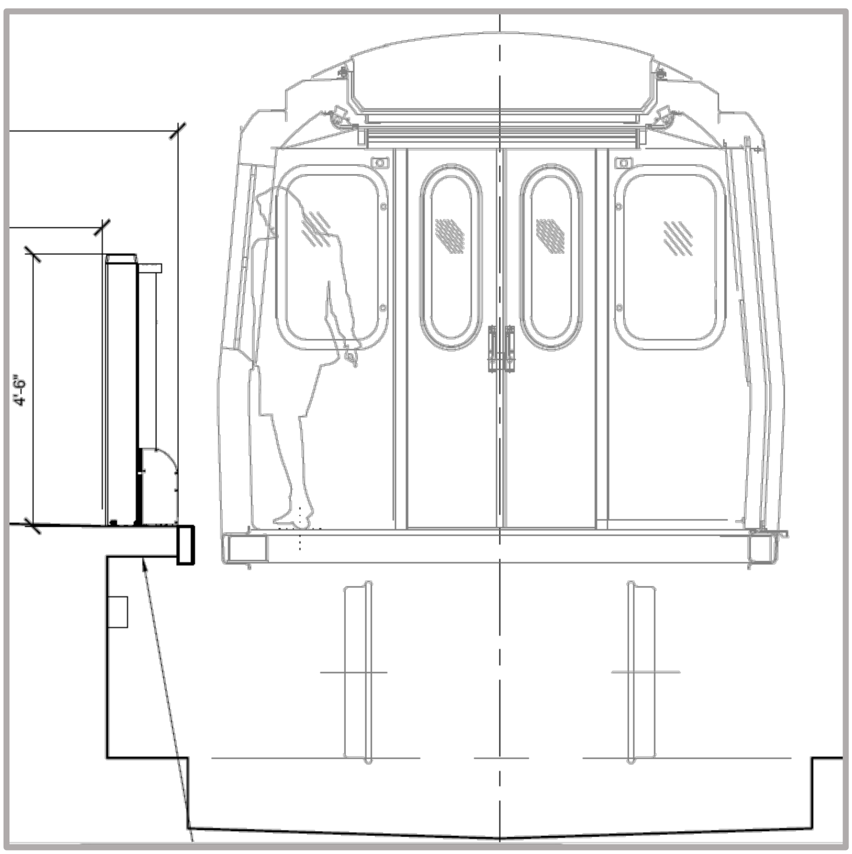


Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 lbs/ft.^{2} (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

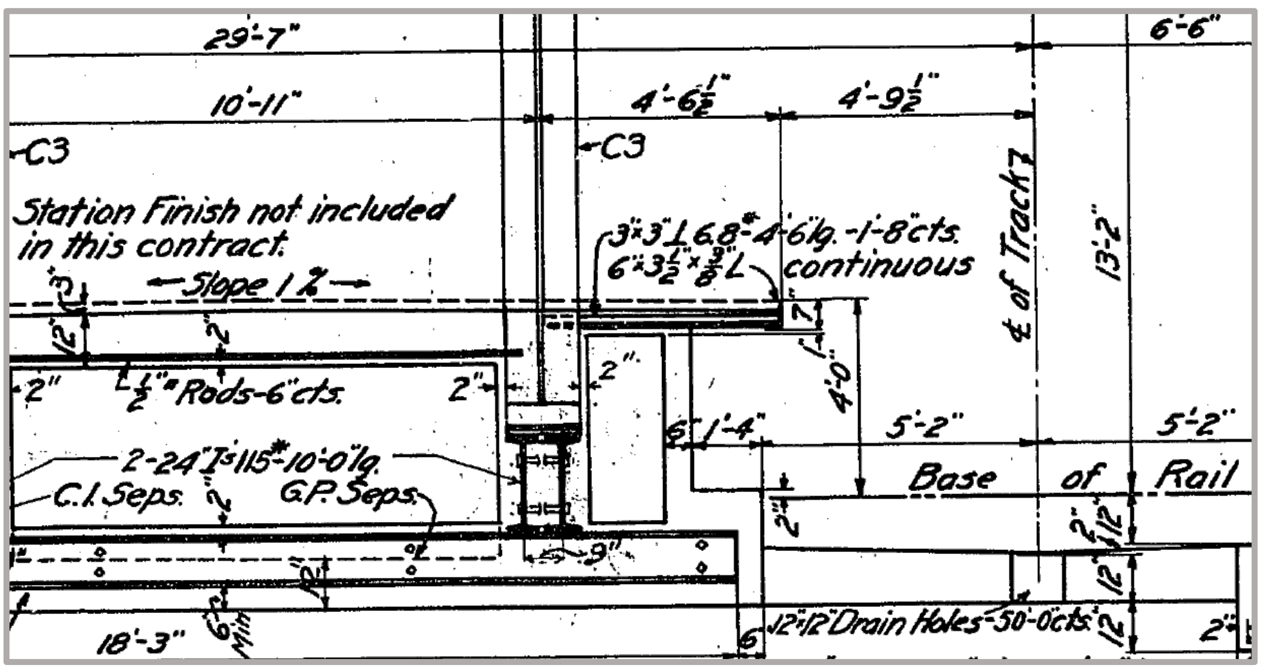

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

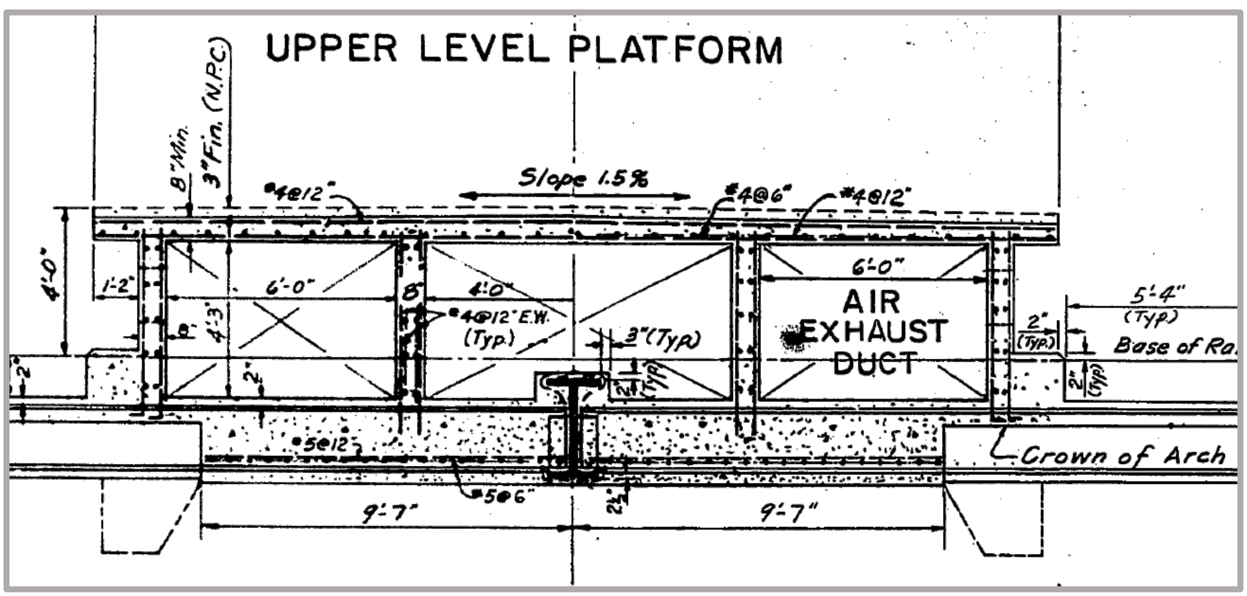

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

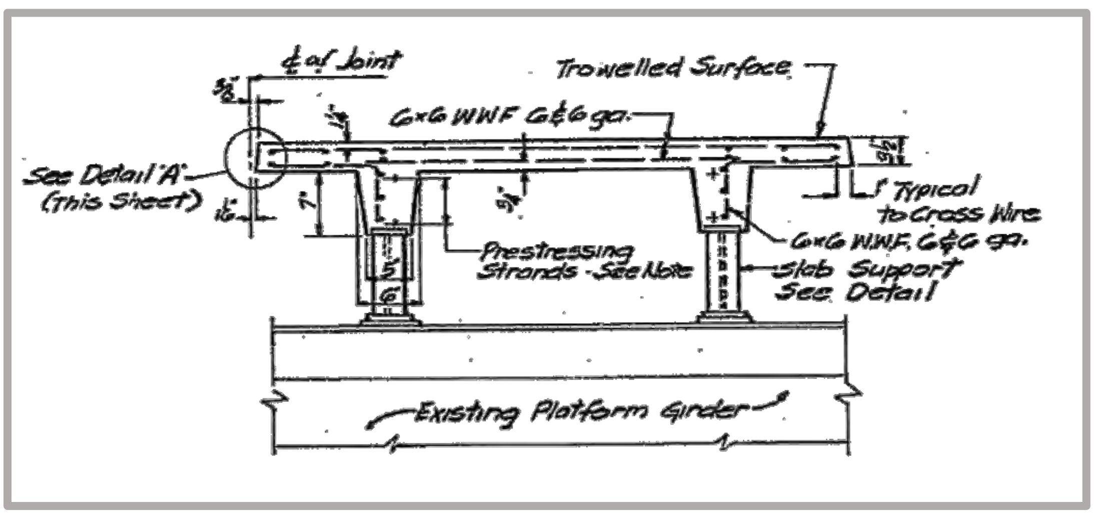

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

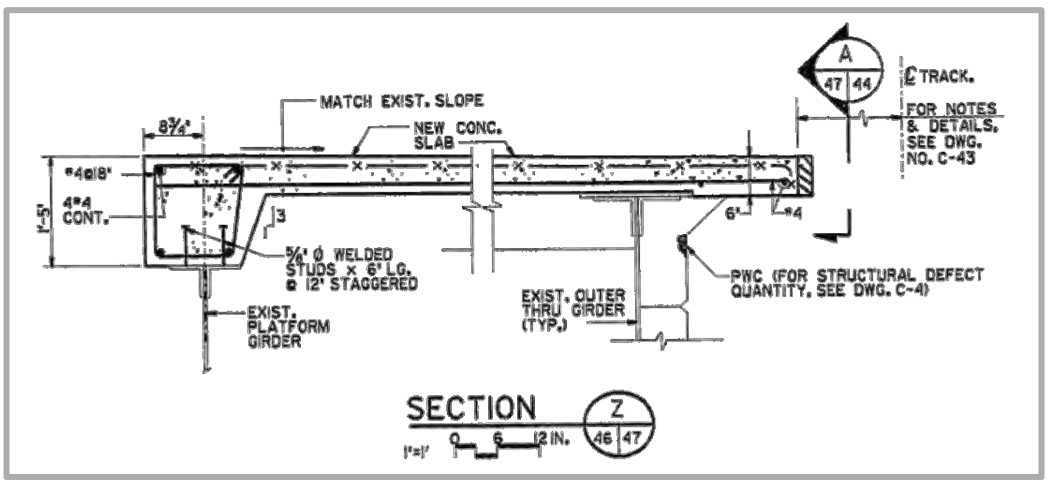

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

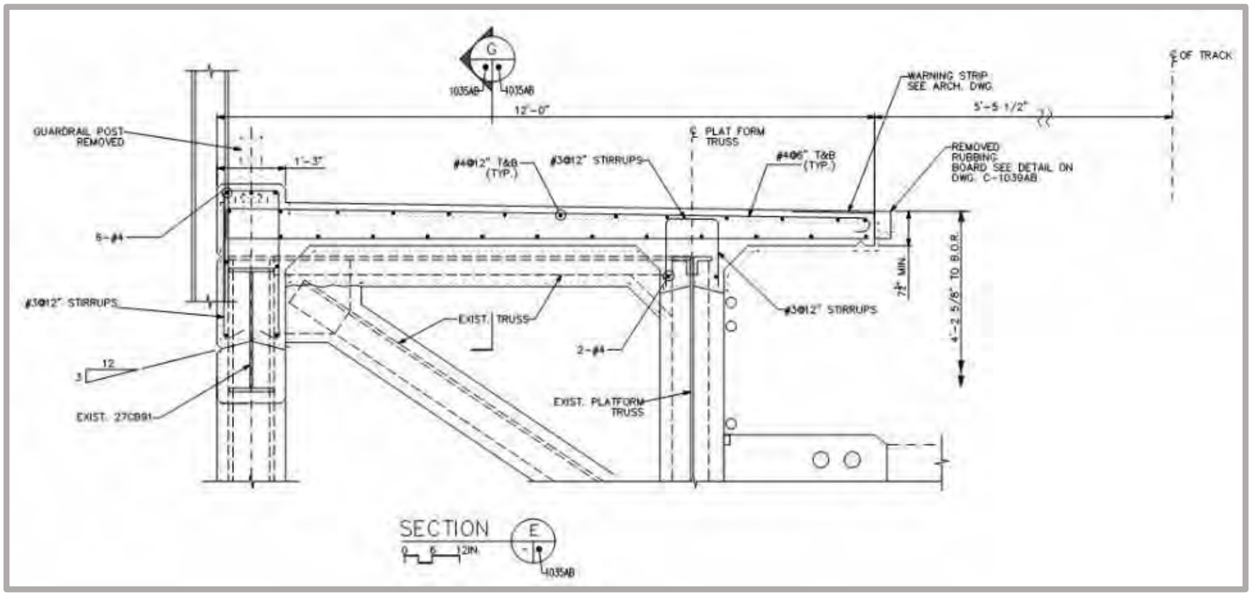

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

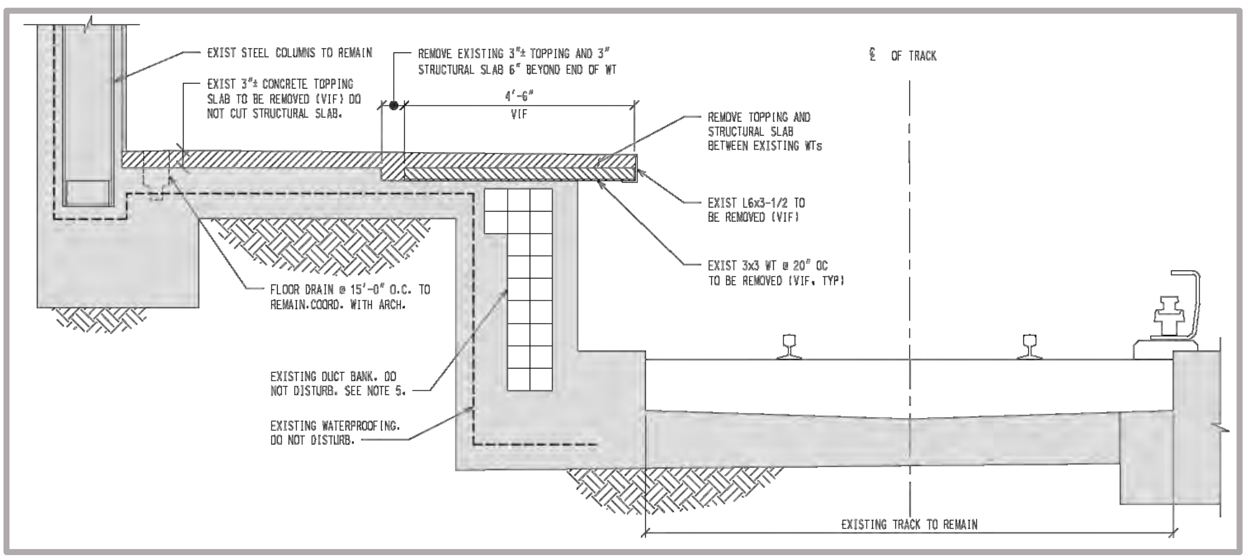

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

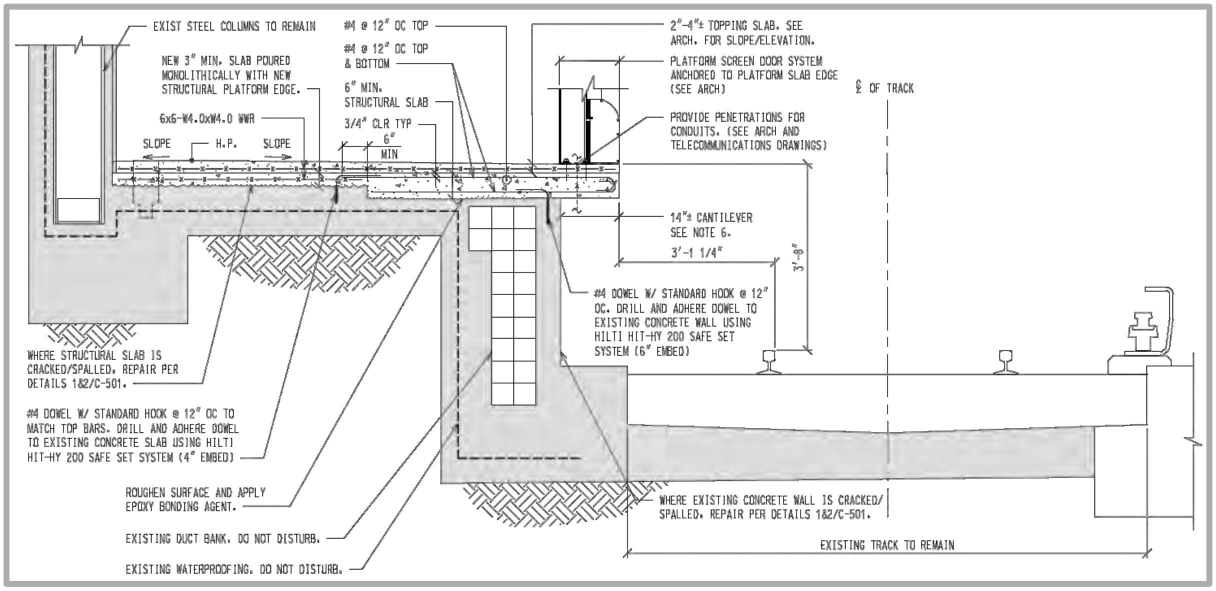

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

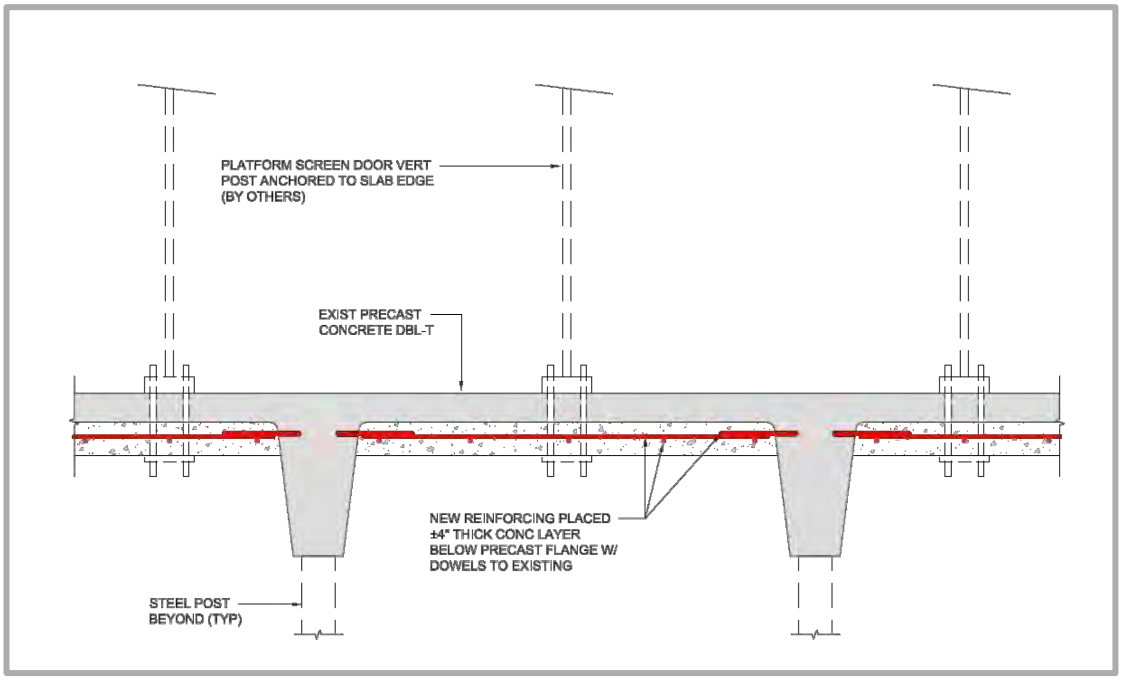

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C

Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

MTA/NYCT

April 11, 2019

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.2 *APGs / PSDs will provide 29 emergency egress doors with push bars per platform*
1.3 *Each platform edge will have 40 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 It is assumed that each train has 10 cars on this line
2.2 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.3 In respect of the PSD option, only platforms that have not been upgraded in the recent past will require platform edge replacement.
2.4 There are no special security requirements made necessary by installation of the APG system
2.5 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.6 This estimate does not provide for the replacement of Platform Edge Lighting
2.7 Premium cost for night time work is considered 50% of total labor cost

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

MTA/NYCT

April 11, 2019

BASIS OF ESTIMATE

3.0 ***Exclusions - Costs not included in the estimate:***

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems
3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length
3.4 Costs associated with NYCT State Of Good Repair improvements to the station
3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.
3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs
3.7 Escalation Cost is not included; Anticipate at 5% per annum.
3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.
3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium
3.10 NYCT project cost is not included
3.11 GO and flagging cost is not included
3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 ***Below the line or "soft" costs:***

4.1 Design and Construction Contingency
4.2 Contractor O & P
4.3 Insurance
4.4 NYCT project costs not included

5.0 ***Additional Notes***

5.1 Given the limited time available, no drawings were developed to support this estimate.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

11-Apr-19

STATION : EAST 149TH STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	534	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	526	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,060**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,060	LF	7	7,420
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,300	SF	12	63,600
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	107	CY	2,500	267,500
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,062	EA	25	26,550
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,062	EA	25	26,550
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,060	LF	95	100,700
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,060	LF	15	15,900
26	Remove existing platform tiles	1,060	LF	12	12,720
27	Sawcut existing topping concrete at perimeter of removal area	1,060	LF	5	5,300
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,360	SF	8	50,880
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width Approx. 12'-6" wide strip	520	SF	8	4,160
30	New Work				
31	New concrete topping to match existing	1,060	SF	15	15,900

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

11-Apr-19

STATION : EAST 149TH STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
32	New concrete topping at ADA boarding area to match existing	520	SF	15	7,800
33	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	360	LF	110	39,600
34	Misc. patchwork	1	LS	50,000	50,000
35					
36	**Equipment Room [7'-0" x 27'-6"]**				
37	Build off existing mezzanine slab		Note		
38	Form 8" wide concrete curb including dowelling to platform slab	42	LF	90	3,735
39	CMU Wall for equipment room	415	SF	45	18,675
40	Vertical connections with existing structure	20	LF	25	500
41	Roof for equipment room	193	SF	30	5,775
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	415	SF	40	16,600
45	Mosaic Band to match existing - Assuming 8" high	42	LF	120	4,980
46	Concrete cove to match existing	42	LF	20	830
47	Interior Wall Finish - Paint	690	SF	5	3,450
48	Allow for Misc. floor & ceiling finishes	193	SF	15	2,888
49	Allow for 4" thick concrete pads for equipment	48	SF	20	963
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
54					
55	**Automatic Platform Gates [APGs] - 4'-6" High**				
56	Automatic bi-parting gates; Assumed 6'-0" wide (10 Cars x 3 Doors = 30 No. per platform)	60	EA	15,000	900,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #29 per Platform	58	EA	10,500	609,000
58	Double egress/service gate in the center of the platform; #1 per Platform	2	EA	20,000	40,000
59	Platform End Gates (PEGs)	4	EA	13,000	52,000
60	Fixed Panels including framing and support; 4'-6" High	2,295	SF	750	1,721,250
61	Spare Parts - Approx. 10% of Material Cost	1	LS	199,335	199,335
62	Testing and commissioning	800	HRS	160	127,944
63	Product Warranty	1	LS	1,000,000	1,000,000
64	Allowance for Braille Signage	60	EA	2,500	150,000
65					
66	**Electrical**				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting				
70	Allowance for Circuit Breakers,Panels, UPS's in connection with PSD's	1	LS	200,000	200,000

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

11-Apr-19

STATION : 103RD STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	550	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	550	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,100**	**LF**

Tier 2-3 Report on Feasibility of Platform Edge Barriers for Train-6 Line Stations

11-Apr-19

STATION : 51ST STREET

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	**GENERAL NOTES**				
2	The estimate detail (lines 1 through 150 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (Page 4) the total of the estimated detail line items below appears as the Total Direct Cost at the top of the page. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. The summary page also contains an Alternative Option Premiums for the Platform Screen Doors in lieu of the APG's.				
4	LENGTH OF THE PLATFORM EDGE [SOUTH BOUND] =	534	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH BOUND] =	534	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	**1,067**	**LF**		
7	NUMBER OF TRAIN CARS ON THIS LINE =	**10**	**CARS**		
8					
9	**AUTOMATIC PLATFORM GATES [APG's]**				
10					
11	**Platform edge reconstruction**				
12	Demolition				
13	Remove existing polyethylene edge strip	1,067	LF	7	7,471
14	Remove 5' wide section of 3" deep structural slab to platform edge	5,337	SF	12	64,040
15	New Work				
16	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	108	CY	2,500	270,000
17	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,069	EA	25	26,734
18	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,069	EA	25	26,734
19	Cast in assemblies for PSD holding down bolts	640	EA	180	115,200
20	Polyethylene edge strip	1,067	LF	95	101,397
21	Provide sleeves for HV & LV wires	248	EA	110	27,280
22					
23	**Platform edge finishes**				
24	Demolition				
25	Remove existing tactile warning strip 2' wide	1,067	LF	15	16,010
26	Remove existing platform tiles	1,067	LF	12	12,808
27	Sawcut existing topping concrete at perimeter of removal area	1,067	LF	5	5,337
28	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	6,404	SF	8	51,232
29	Remove existing 3" concrete topping at 40' long ADA boarding area; Balance of platform width i.e. 10' wide strip	520	SF	8	4,160
30	New Work				
31	New concrete topping to match existing	1,067	SF	15	16,010

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR '7' (FLUSHING) LINE STATIONS

CONTRACT #: C-32514 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: July 23, 2018

STV 100 Years

Table of Contents

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C
- A study of the entire Canarsie L-line

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations.

The Tier 1 analysis of door arrangement in the vehicles dedicated to the Flushing Line found that there are no problems of incompatibility; one train car type (R188) and one train consist will be run on the Flushing line for the foreseeable future (the assumed design year for this study is between 2018 and 2032). In addition, this will be the second line in the NYCT system to receive computer based train control (CBTC) enabling the stop location of the trains to be consistent. This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

There are a total of 22 stations included in this study. Seven of the stations are below-grade and the remaining stations are elevated. Some of these stations have three tracks, offering express service or additional service related to specific events (in this case, Mets games). The stations are a mix of center/island and side platforms.

Of these 22 newly evaluated stations, 15 have been found to be not suitable for the installation of PSDs. The reasons for this finding vary but are generally related to space constraints and existing structure.

[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to low-height barriers]

The following summarizes the major findings:

- ADA clearance issues; the platform edge barriers are 15" wide. Where an existing object (wall, stair, railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Where these PSDs hamper the ability of a wheelchair to turn (a 5'-0" circle) and/or limit path of travel to less than 32", it is declared infeasible.
- Insufficient space for the PSD equipment room; the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 16'). Many stations do not have available space for these rooms.
- Platforms that are too narrow; due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements in regard to the placement of these new barriers in an existing station environment.

- Structural considerations; existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the wall and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used at all stations on the Flushing "7" Line. For a PSD installation, It is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. As example, evidence of damage from these carts is readily visible along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings, and shows that platform edge barriers are feasible at 32% of the "7" (Flushing) Line stations. Total implementation cost would be $283.0M for APGs and $353.3M for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; That estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 7 feasible stations, the aggregate annual maintenance cost would be $6,517,000.

'7' (Flushing) Line Summary of Feasibility (32% feasible; 7/22)

No.	Station Name	Station Type	Platform Type	Feasible Yes / No	Issues / Reason for Failure	Cost APGs	Cost PSDs
MR-447	Flushing-Main Street	Below-grade	Center/Island	Yes		$60.0M	$75.2M
MR-448	Mets-Willets Point	Elevated	Side and Center/Island	Yes		$59.7M	$74.7M
MR-449	111th Street	Elevated	Side	No	• ADA clearance		
MR-450	103rd Street-Corona Plaza	Elevated	Side	No	• Precast platform (Appendix B)		
MR-451	Junction Boulevard	Elevated	Center/Island	No	• Precast platform (Appendix B)		
MR-452	90th Street-Elmhurst	Elevated	Side	No	• Precast platform (Appendix B)		
MR-453	82nd Street-Jackson Heights	Elevated	Side	No	• Precast platform (Appendix B)		
MR-454	74th Street-Broadway	Elevated	Center/Island	No	• Precast platform (Appendix B)		
MR-455	69th Street-Fisk Avenue	Elevated	Center/Island	No	• Precast platform (Appendix B)		
MR-456	61st Street-Woodside Avenue	Elevated	Side	No	• Precast platform (Appendix B)		
MR-457	52nd Street-Lincoln Avenue	Elevated	Center/Island	No	• Precast platform (Appendix B)		
MR-458	47th Street-Bliss Street	Elevated	Side	No	• ADA clearance		
MR-459	40th Street-Lowery Street	Elevated	Side	No	• ADA clearance		
MR-460	33rd Street- Rawson Street	Elevated	Side	No	• ADA clearance		
MR-461	Queensboro Plaza	Elevated	Center/Island	Yes		$32.8M	$41.3M
MR-462	Court Square	Elevated	Side	No	• No space for equipment room		
MR-463	Hunters Point Avenue	Below-grade	Side	No	• ADA clearance		
MR-464	Vernon Blvd-Jackson Ave	Below-grade	Side	Yes		$32.9M	$41.2M
MR-465	42nd Street-Grand Central	Below-grade	Center/Island	Yes		$33.1M	$41.5M
MR-466	5th Avenue-Bryant Park	Below-grade	Center/Island	No	• ADA clearance		
MR-467	42nd Street-Times Square	Below-grade	Center/Island	Yes		$31.4M	$38.8M
MR-471	34th Street-Hudson Yards	Below-grade	Center/Island	Yes		$33.1M	$40.6M
					Total Estimated Cost	$283.0M	$353.3M

1.0 Station Assessments

1.1 Flushing-Main Street Station

Summary: Flushing-Main Street (MR-447) is feasible for both APGs and PSDs. As a terminating station, Main Street Station serves Hudson Yards-bound local and express trains. Train signal boxes on tracks 1 and M, would have to be relocated in the implementation of PSDs. As the platform edge appears to be recently renovated, structural work would only be required in the implementation of APGs (see structural report; Appendix B). Existing power is adequate.

Description

Main Street Station is a below-grade station with two mildly curved center/island platforms. There are three tracks (Tracks 1, M, and 2). Track 1 is to the north of the station, track M is in the middle (accessed on both sides), and track 2 is to the south of the station. Track 1 is for the local train while Tracks M and 2 provide express service (see figure 1 for the station plan). Access from the mezzanine level to the platforms are provided at multiple locations along the platform length. The platform structure is cast-in-place concrete. Back-of-house elements are located at the ends of the platform and in the mezzanine. The columns on the east end of the platforms are larger due to their tile surround and are spaced 18'-0" on center, while remaining steel columns are 15'-0" on center. Typically, the platform widths are approximately 19'-0". Both platforms taper at their ends, the narrowest width is approximately 14'-4" wide (see figure 3 for a typical platform view). Generally, there is a vertical clearance of approximately 8'-0" to the ceiling at the platform edge. Train signal boxes that hang over the platform edge at track 1 and M, reduce the vertical clearance to 7'-2".

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Train signal boxes on tracks 1 and M would need to be relocated in the implementation of full height PSDs (see figure 4).

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Hung conduit below the platform edge would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

As there are four platform edges requiring platform edge barriers, there is a need for a larger equipment room. The equipment room can be located at the west-end of the mezzanine level with approximate dimensions of 14'-0" x 26'-6" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.`

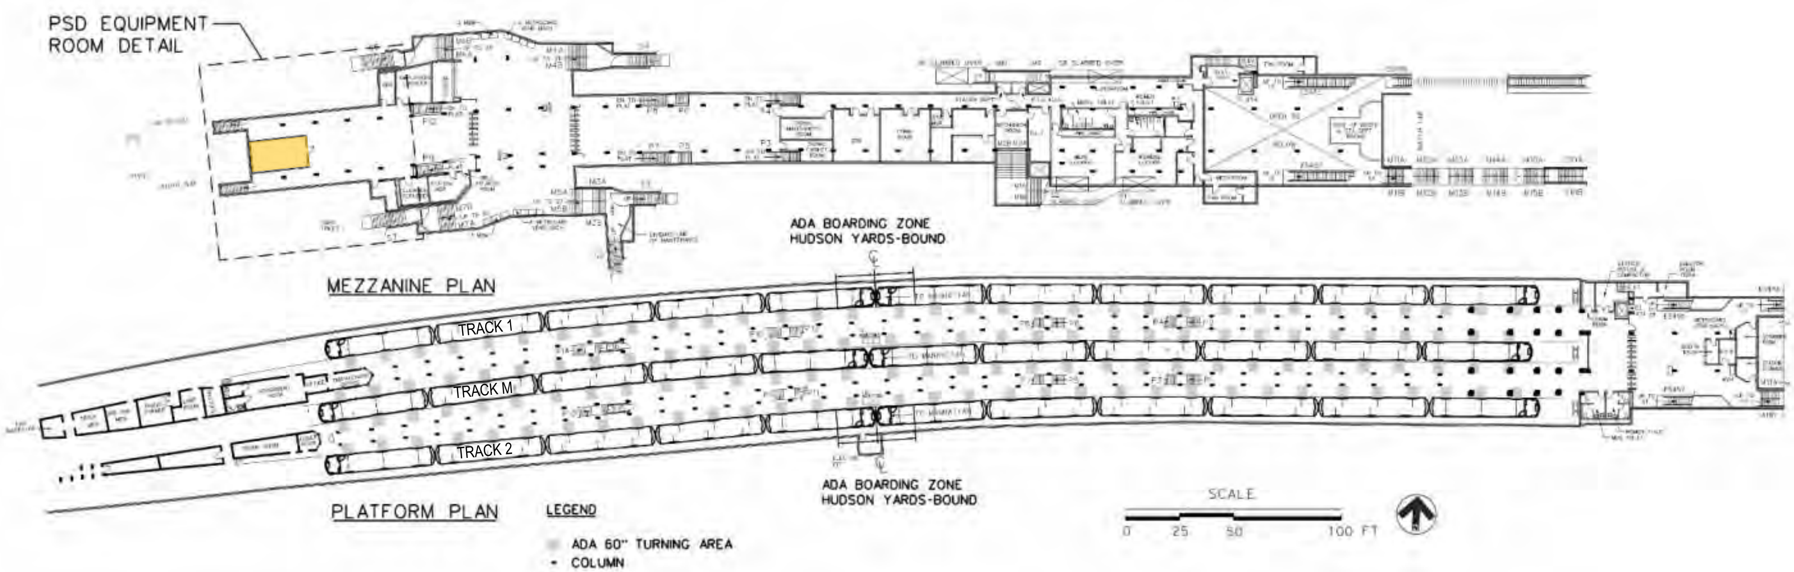

Figure 1 – Station Plan- Flushing-Main Street Station

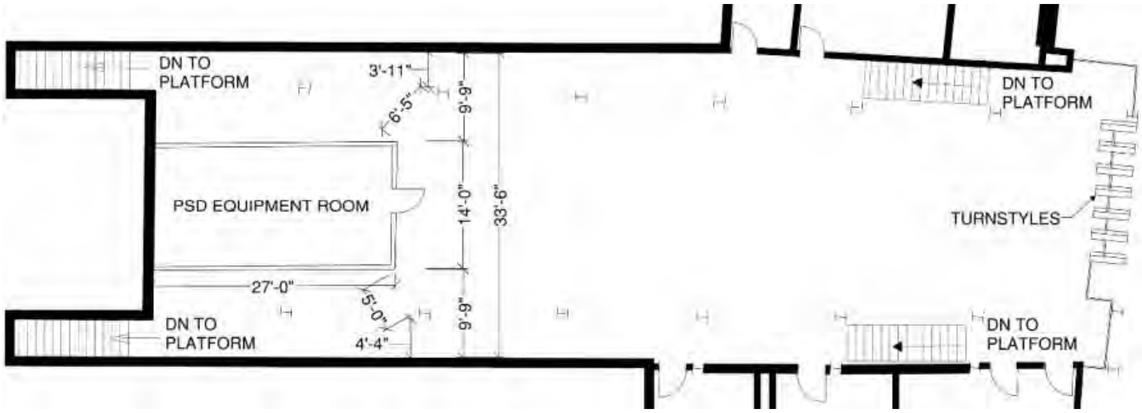

Figure 2 – PSD Equipment Room Detail – Flushing-Main Street Station

Platform Edge Condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 3. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

Northern Platform: Typically, columns are approximately 5'-6" from the platform edge. At the east-end of the platform, eight columns are 17" from the platform edge.

Southern Platform: Typically, columns are approximately 5'-6" from the platform edge. At the east-end of the platform, four columns are 17" from the platform edge; additionally, four columns are 3'-0" from the platform edge.

The use of 22" emergency egress hinged doors is impeded by approximately 4 existing columns (total on all platforms). As there are so few emergency egress doors impeded by the atypical condition at the east-end of the platforms, this station is still feasible.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alternations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table on the following page. Calculation is based on APG loads which are the most demanding.

Flushing Line Station Electrical Capacity Analysis	
NYC T Station MR Number	447
Station Name	Flushing - Main St
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	142.4
Peak Demand Load, Max Current (A)	494.1
PSD Total Load for 64 Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	659
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	541
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

Main Street Station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $60.0M to install APGs and $75.2M to install PSDs (See Appendix E)

1.2 Mets-Willets Point Station

Summary: Mets-Willets Point (MR-448) is feasible for both APGs and PSDs. Mets-Willets Point Station functions to accommodate users differently on game days and non-game days. To accommodate the surge in passengers, and to ensure that ADA routes are available on game days, additional tracks are used compared to a non-game day. Platform structural work would be required to support the added load of the platform edge barrier (see structural report; Appendix B). Existing power is adequate.

Description

Mets-Willets Point Station is an elevated station with three tracks serviced by two straight side and one center/island platform. The platforms are accessed at their centers with back-of-house elements below and at the ends of the platforms. Typically (non-game days), one side platform (track 1- Hudson Yards-bound) and the center platform (track 2- Flushing-Main Street-bound) are used. This station operates differently on game days to accommodate the many passengers arriving/departing from Citi Field. On game days, Track M accessed from the center/island platform runs additional Flushing-bound trains before the game and additional Hudson Yards-bound trains after the game. The side platform which is typically not used is opened on game days allowing for an ADA-accessible route to the stadium and mitigates large groups of passengers arriving at the station. If platform edge barriers were to be installed, they would be required at all four platform edges. See figure 1 for the Mets-Willets Point station plan. The platform structure is cast-in-place concrete. Along the length of all platforms, columns are typically spaced 20' on center. Both side platforms are approximately 22' wide. The center/island platform is approximately 24'-6 wide. About ¾ of the platform length is covered by a canopy. Typically, there is a vertical clearance of approximately 8'-0" to canopy beams at the platform edge (see figure 4 for a typical platform edge view).

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As about ¼ of the platform length is not covered by an overhead structure, an overhead structure would be required to install full height PSDs.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edge would need to be relocated to accommodate the requirements of the APG system. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies.

Equipment Room

As there are four platform edges requiring platform edge barriers, two full equipment rooms are required. These rooms can be located at the west-end of both side platforms. Both rooms would measure approximately 27'-0" x 7'-6" (see figures 2 and 3)

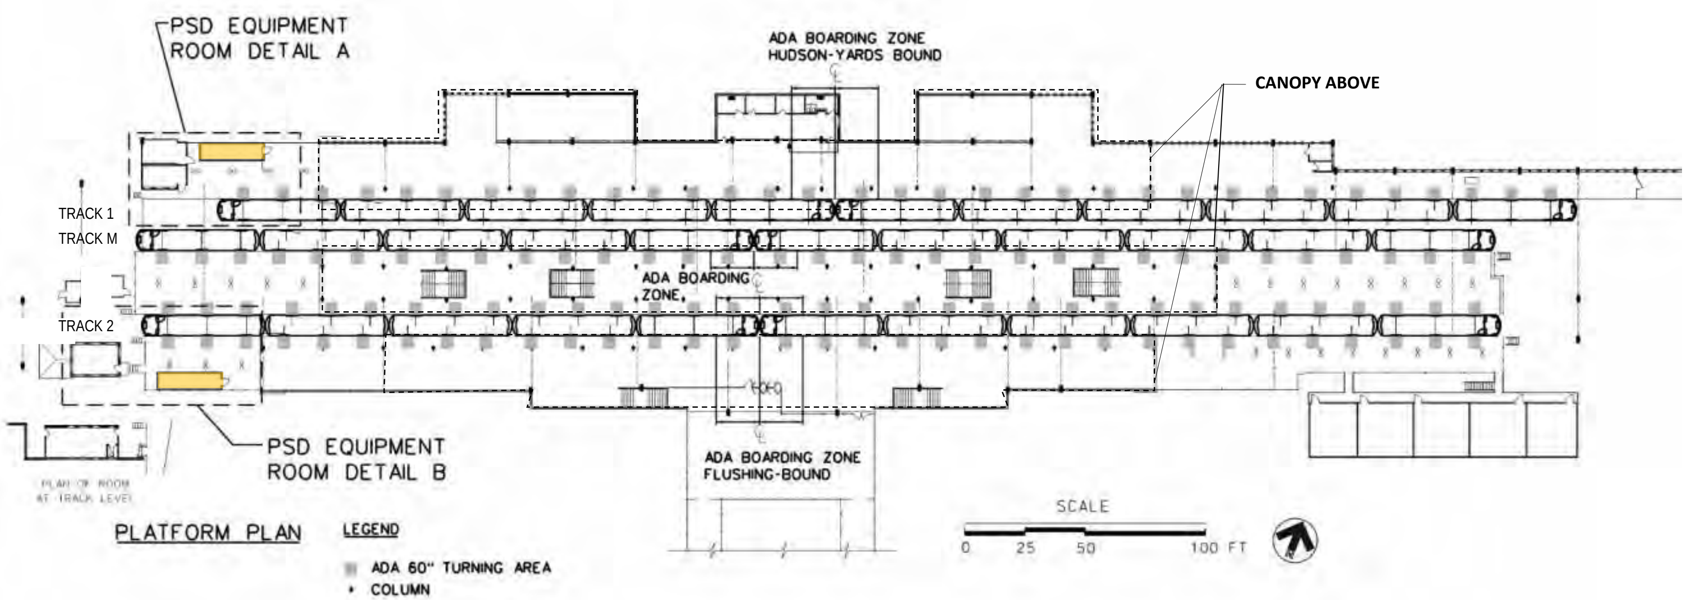

Figure 1 – Station Plan- Mets-Willet Point Station

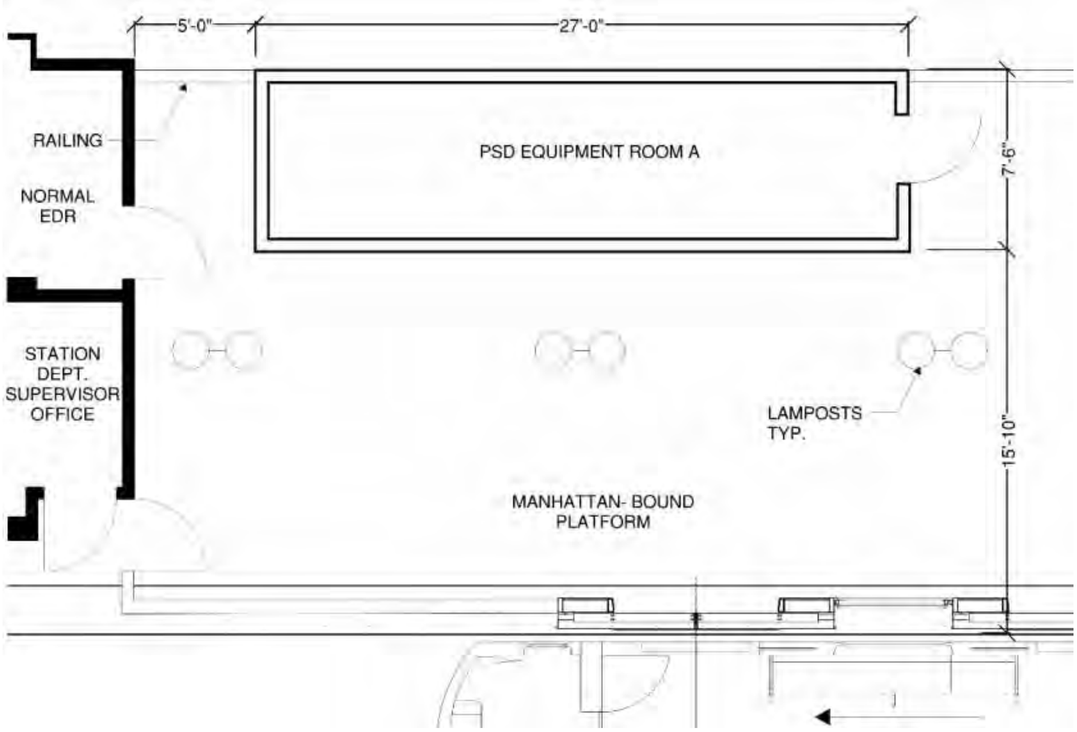

Figure 2 – PSD Equipment Room A Detail – Mets-Willets Point Station

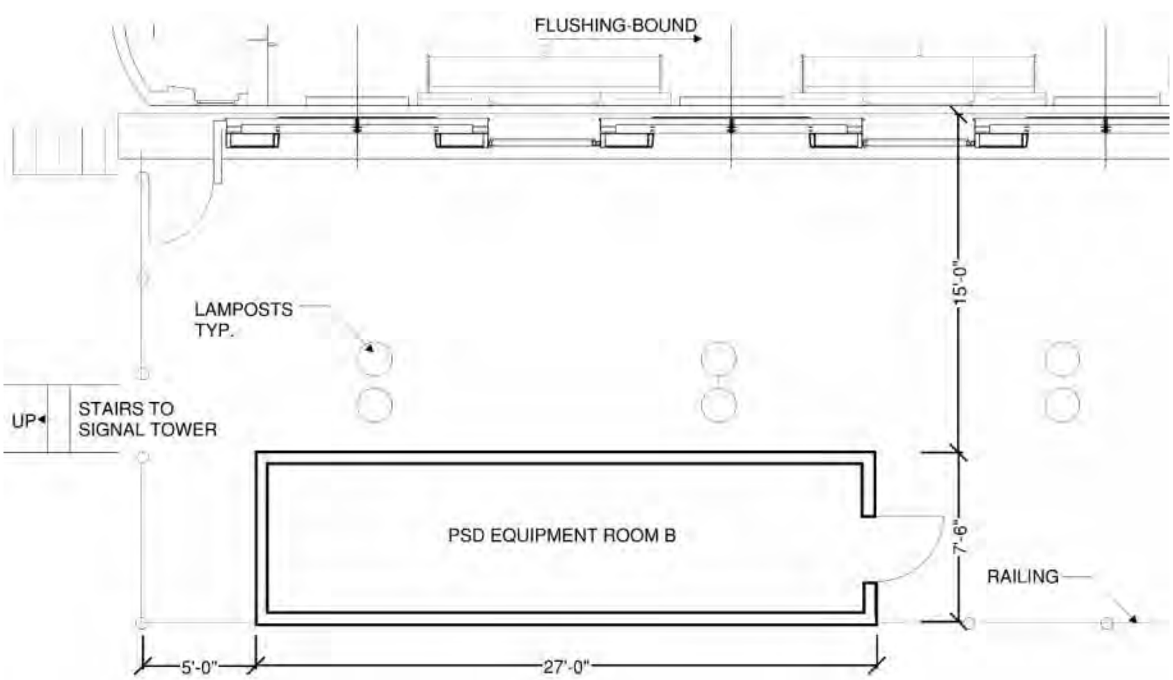

Figure 3 – PSD Equipment Room B Detail - Mets-Willets Point Station

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would be required for the installation of a PSD or APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.75. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

Flushing-bound (side platform): Column faces are typically 4'-4' from the platform edge. There are no obstructions at the ADA-designated doors

Center/Island Platform: Column faces are approximately 6'-0" from the platform edge. There are no obstructions at the ADA-designated doors

Hudson Yards-bound (side platform): Same as Flushing-bound conditions (see above).

Figure 4 – Typical platform view- Mets-Willets Station

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge with a vertical clearance of 7'-0". Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Flushing Line Station Electrical Capacity Analysis	
NYC T Station MR Number	448
Station Name	Mets - Willets Point
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	117.6
Apparent Power (kVA)	147.0
Peak Demand Load, Max Current (A)	408.0
PSD Total Load for 64 Doors, including All Miscellaneous Loads, (A)	165.0
Total Load (Station Peak + PSD), (A)	573
Station Service Power Capacity, (A)	1200
Service Spare Capacity, (A)	627
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $59.7M to install APGs and $74.7M to install PSDs (See Appendix E)

1.3 111th Street Station

Summary: 111th Street Station (MR-449) is not feasible for APGs or PSDs as they would create non-compliant ADA conditions. The stairs at this station align with the back of the platform and typically leave a clear path of 3'-4" for circulation along the length of the platform. This condition currently complies with ADA requirements. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would only be 25" (see figure 1)

Description

111th Street Station is an elevated station with straight side platforms. The platform structure is cast-in-place concrete. The platform widths vary slightly, but range from 7'-0" to approximately 10'-6". There are three staircases on each platform. Passengers currently walk in the clear space between the stair and platform edge (3'-4") to move along the length of the platform (see figures 1 and 2). Approximately 4/5 of the platform is covered by a canopy.

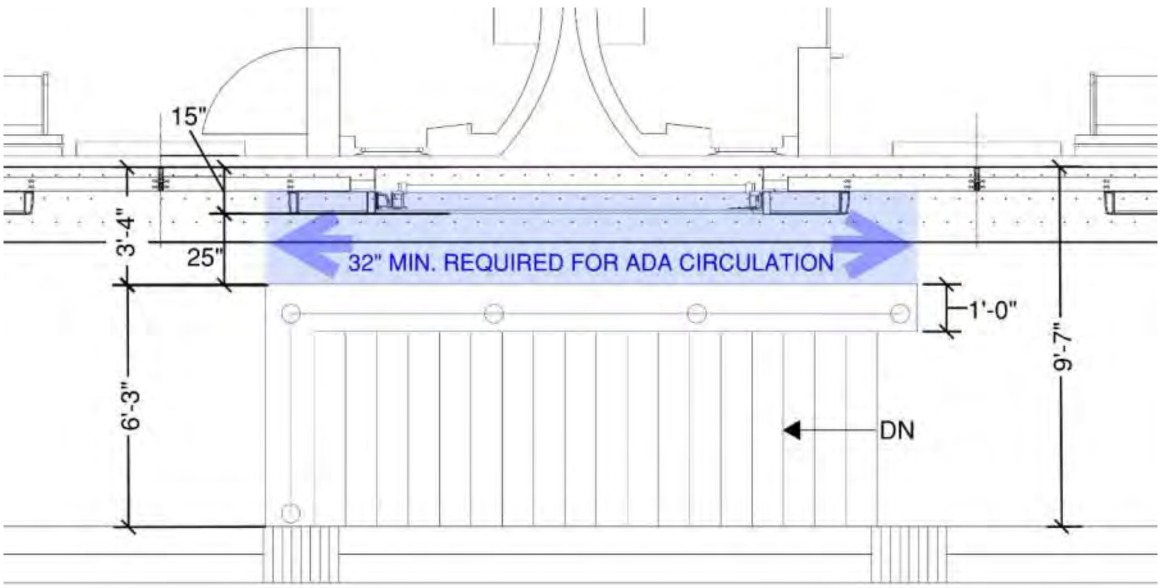

Figure 1– Typical platform condition at stairs – 111th Street Station

Table of Contents

Figure 2 – Typical stair location and platform condition – 111th Street Station

Table of Contents

1.4 103rd Street-Corona Plaza Station

Summary: 103rd Street-Corona Plaza Station (MR-450) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

103rd Street-Corona Plaza Station is an elevated station with two side platforms. Both platforms are straight with columns along the length of the platform supporting the canopy. The canopy covers about 2/3 of the station, with parts of the station uncovered at both ends (see figure 1). If the station was deemed feasible, an overhead structure would be required to install a platform edge barrier where there is currently no canopy.

Figure 1 – Typical platform condition – 103rd Street-Corona Plaza Station

Figure 2 – Precast T-Beam platform – 103rd Street-Corona Plaza Station

1.5 Junction Boulevard Station

***Summary:** Junction Boulevard Station (MR-451) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description

Junction Boulevard Station is an elevated station with two center/island platforms. Both platforms are straight with columns along the platform. The canopy covers about half of the station (see figure 1). If the station was deemed feasible, an overhead structure would be required to install a platform edge barrier where there is currently no canopy.

Figure 1– Typical platform condition – Junction Boulevard Station

Table of Contents

Figure 2 – Precast T-Beam platform – Junction Boulevard Station

1.6 90th Street-Elmhurst Street Station

Summary: 90th Street-Elmhurst Street Station (MR-452) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

90th Street-Elmhurst Street Station is an elevated station with two side platforms. Both platforms are straight with columns along the length of the platform supporting the canopy. The canopy covers about half of the platform (see figure 1). If the station was deemed feasible, an overhead structure would be required to install a platform edge barrier where there is currently no canopy.

Figure 1 – Typical platform view (much of platform is not covered by a canopy) – 90th Street-Elmhurst Street Station

Figure 2 – Precast T-Beam platform – 90th Street-Elmhurst Street Station

1.7 82nd Street-Jackson Heights Station

Summary: 82nd Street-Jackson Heights Station (MR-453) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

82nd Street-Jackson Heights Station is an elevated station with two side platforms. Both platforms are straight with columns along the platform supporting the canopy. The canopy covers about half of the station, with parts of the station uncovered at both ends (see figure 1).

Figure 1 – Considerable Portion of the Platform Not Covered – 82nd Street-Jackson Heights Station

Table of Contents

1.8 74th Street-Broadway Station

Summary: 74th Street-Broadway Station (MR-454) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

74th Street-Broadway Station is an elevated station with two side platforms. Both platforms are straight with columns along the platform supporting the canopy. The canopy covers the majority of the platform length. See figure 1 for a typical platform view.

Figure 1–Typical Platform Condition – 74th Street- Broadway Station

Figure 2–Precast T-Beam Platform – 74th Street- Broadway Station

1.9 69th Street-Fisk Avenue Station

Summary: 69th Street-Fisk Avenue Station (MR-454) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

69th Street-Fisk Avenue Station is an elevated station with two side platforms. Both platforms are straight with columns along the platform supporting the canopy. The canopy covers about half of the station, with parts of the station uncovered at both ends (see figure 1).

1.10 61st Street-Woodside Avenue Station

***Summary:** 61st Street-Woodside Avenue Station (MR-456) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).*

Description

61st Street-Woodside Avenue Station is an elevated station with two island/center platforms. Both platforms are straight with columns along the platform supporting the canopy. The canopy covers the majority of the station. See figure 1 for a typical platform view.

Figure 1– Typical Platform Condition – 61st Street-Woodside Avenue Station

Figure 2– Precast T-Beam Platform – 61st Street-Woodside Avenue Station

1.11 52nd Street-Lincoln Avenue Station

Summary: 52nd Street-Lincoln Avenue Station (MR-457) is not feasible for APGs or PSDs due to the elevated Precast T-Beam platform which has been deemed structurally insufficient to carry the load of a platform edge barrier system (see structural report; Appendix B and figure 2).

Description

52nd Street-Lincoln Avenue Broadway Station is an elevated station with two side platforms. Both platforms are straight with columns along the platform supporting the canopy. The canopy covers the majority of the station. See figure 1 for a typical platform view.

Figure 1 – Typical platform condition – 52nd Street-Lincoln Avenue Station

Figure 2 – Precast T-Beam platform – 52nd Street-Lincoln Avenue Station

1.12 46th Street-Bliss Street Station

Summary: 46th Street- Bliss Street Station (MR-458) is not feasible for APGs or PSDs as they would create non-compliant ADA conditions. The stairs at this station align with the back of the platform and typically leave a clear path of 3'-4" for circulation along the length of the platform. This condition currently complies with ADA requirements. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would only be 25" (see figure 1)

Description

46th Street-Bliss Street Station is an elevated station with straight side platforms. The platform structure is cast-in-place concrete. The platform widths vary slightly, but range from 7'-0" to approximately 10'-6". There are four staircases on each platform. Passengers currently walk in the clear space between the stair and platform edge (3'-4") to move along the length of the platform (see figures 1 and 2). Approximately 2/3 of the platform is covered by a canopy.

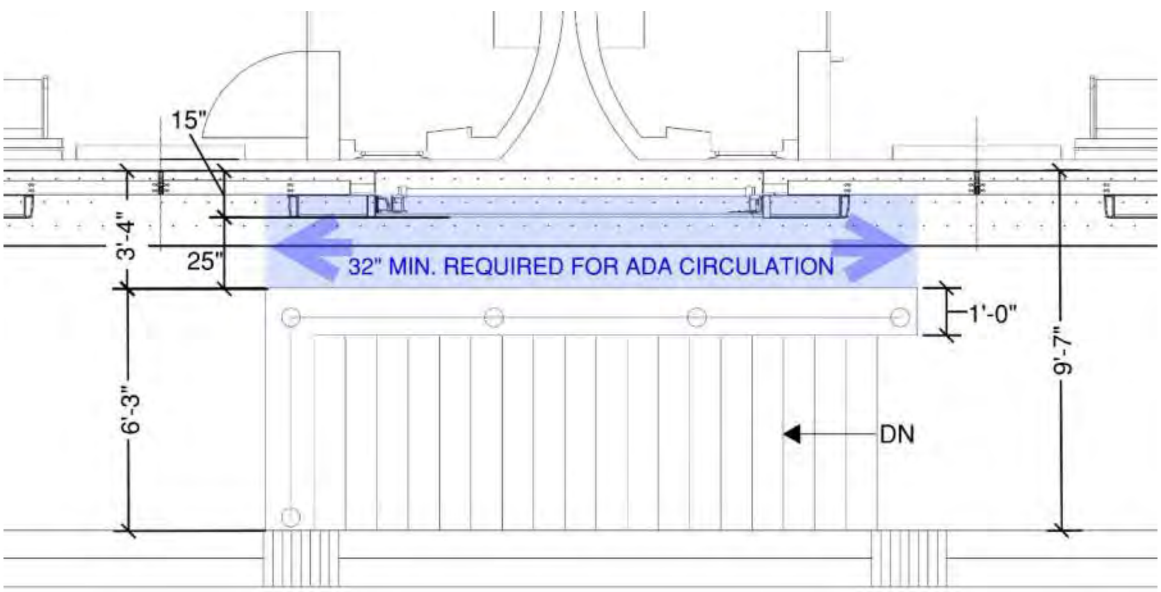

Figure 1 – Typical platform condition at stairs – 46th Street-Bliss Street Station

Figure 2 – Typical stair location and platform condition – 46th Street-Bliss Street Station

1.13 40th Street-Lowery Street Station

Summary: 40th Street-Lowery Street Station (MR-459) is not feasible for APGs or PSDs as they would create non-compliant ADA conditions. The stairs at this station align with the back of the platform and typically leave a clear path of 3'-4" for circulation along the length of the platform. This condition currently complies with ADA requirements. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would only be 25" (see figure 1)

Description

40th Street-Lowery Street Station is an elevated station with straight side platforms. The platform structure is cast-in-place concrete. The platform widths are approximately 9'-7". There are two staircases on each platform. Passengers currently walk in the clear space between the stair and platform edge (3'-4") to move along the length of the platform (see figures 1 and 2).

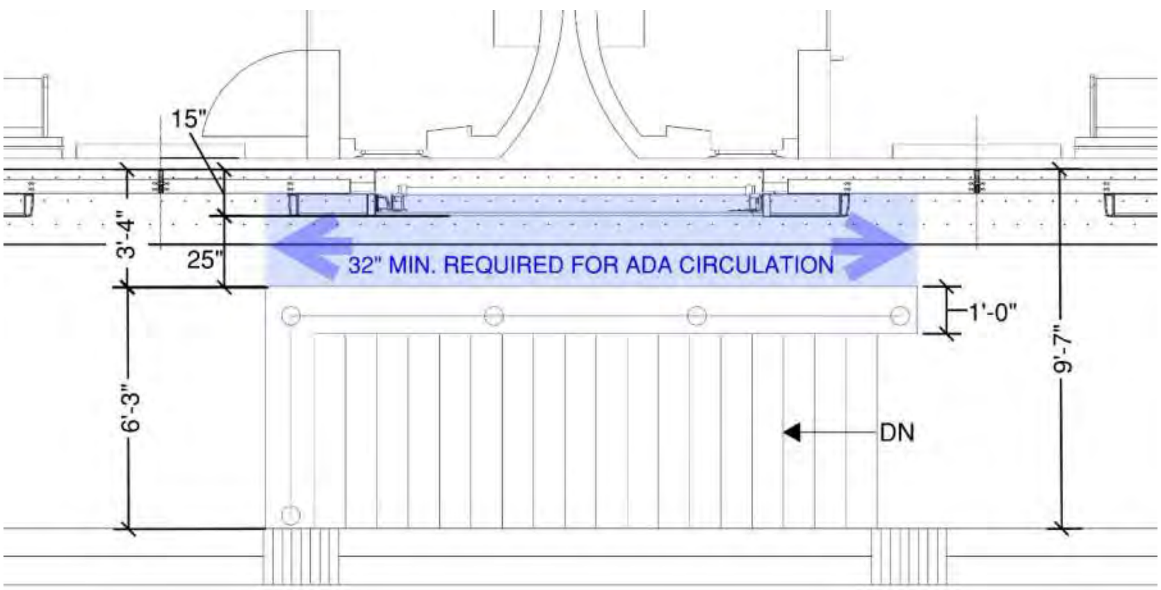

Figure 1– Typical platform condition at stairs – 40th Street-Lowery Street Station

Figure 2 – Typical stair location and platform condition – 40th Street-Lowery Street Station

Table of Contents

1.14 33rd Street- Rawson Street Station

Summary: 33rd Street- Rawson Street Station (MR-460) is not feasible for APGs or PSDs as they would create non-compliant ADA conditions. The stairs at this station align with the back of the platform and typically leave a clear path of 3'-4" for circulation along the length of the platform. This condition currently complies with ADA requirements. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would only be 25" (see figure 1).

Description

33rd Street- Rawson Street Station is an elevated station with straight side platforms. The platform structure is cast-in-place concrete. The platform widths vary slightly, but range from 6'-0" to approximately 9'-7". There are four staircases on each platform. Passengers currently walk in the clear space between the stair and platform edge (3'-4") to move along the length of the platform (see figures 1 and 2).

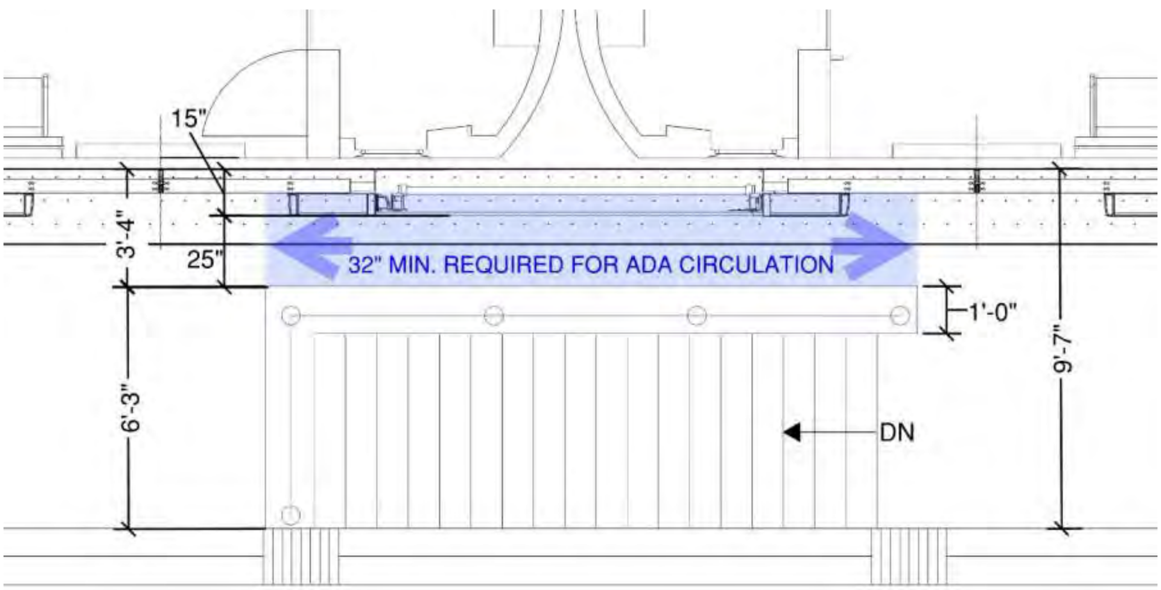

Figure 1– Typical platform condition at stairs – 33rd Street- Rawson Street Station

Figure 2 – Typical stair location and platform condition –33rd Street- Rawson Street Station

1.15 Queensboro Plaza Station

Summary: Queensboro Plaza Station (MR-461) is feasible for both APGs and PSDs. The "7", "N" and "W" trains are served on both the upper & lower levels, with the 7 train and N/W trains on opposite sides of the island platforms. The N/W sides of these platforms will be the subject of a future station report. There is a column in front of an ADA-designated door on both the upper & lower level platforms which is currently not compliant; this condition would not be exacerbated in the implementation of a platform edge barrier. The vertical clearance at the platform edge on both platforms is only 7'-2" in isolated locations. This is a potential obstacle for the installation of full height PSDs. Platform structural work will be required to support an APG system (see structural report; Appendix B). Existing power is adequate.

Description

Queensboro Plaza Station is elevated with two straight center/island platforms stacked on top of each other. Both platforms are accessed via an elevated mezzanine below the lower platform (southbound trains). See figure 1 for an overall station plan. Both platforms are made of cast-in-place concrete. Back-of-house elements are situated at the mezzanine level and both ends of the southbound platform. On the southbound platform, columns are spaced 48' on center with column faces 4'-8" from the platform edge. On the northbound platform, columns are spaced 24' on center with column faces 2'-2" from the platform edge. Both platforms are approximately 19'-6" wide. On the southbound platform, there is a vertical clearance of approximately 8'-0", which reduces to 7'-2" at the east-end of the platform. On the northbound platform, there is a vertical clearance of approximately of 7'-2" to canopy beams at the platform edge. The majority of the upper platform is covered by a canopy. See figures 3 and 4 for typical platform edge conditions at both levels.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As about 1/6 of the upper level platform length is not covered by an overhead structure, an overhead structure would be required to install full height PSDs.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall mounted conduits below the upper and lower platform edge would need to be relocated to accommodate the requirements of the APG system. Minimal overhead structure would be needed to accommodate cameras and sensors in the small portion of the platforms not covered by canopies

Equipment Room

One room can be accommodated at the eastern end of the southbound platform. The proposed room would measure approximately 27' x 7'-6" (see figure 2). As there are four platform edges at this station, two equipment rooms would be needed to accommodate all of the required equipment. An additional room can be located in a similar location on the northbound platform.

Table of Contents

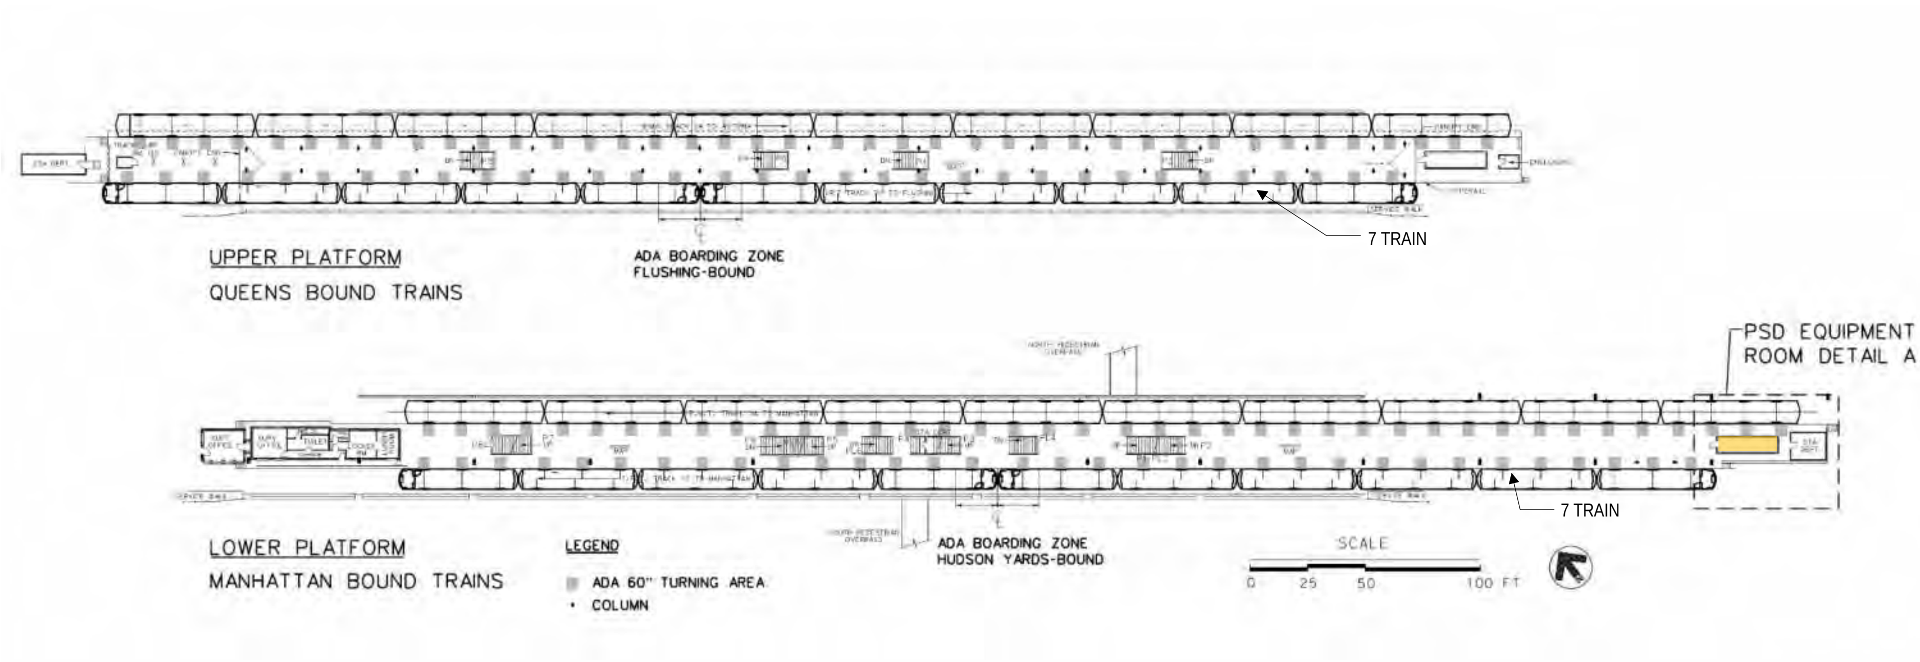

Figure 1 – Station Plan- Queensboro Plaza Station

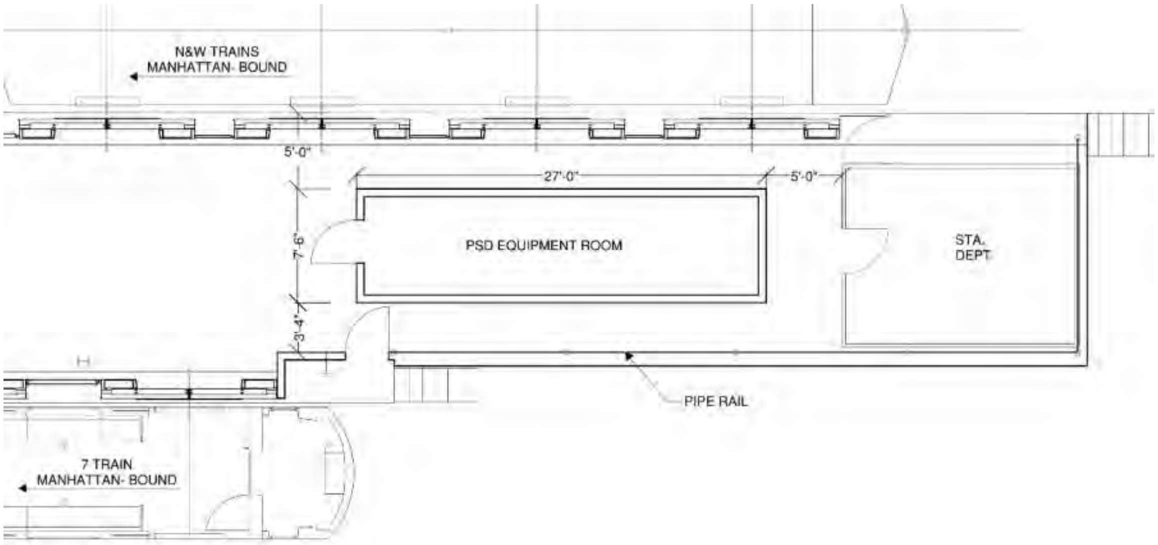

Figure 2 – PSD Equipment Room Detail - Queensboro Plaza Station

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.6. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

Hudson Yards-bound (Southbound): All columns are 26" from the Hudson Yards platform edge. One is in front of an ADA-designated door, however the implementation of a platform edge barrier would not exacerbate this already non-compliant condition.

Flushing-bound (Northbound): All columns are 51" from the platform edge. One column is in front of an ADA-designated door, however critical ADA dimensions are met.

Lighting:

Existing lighting: Linear fluorescent; approximately 1' from platform edge for southbound and centered under canopy on the northbound platform. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table on the following page. Calculation is based on APG loads which are the most demanding.

Flushing Line Station Electrical Capacity Analysis	
NYC T Station MR Number	461
Station Name	Queensboro Plaza
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	163
Apparent Power (kVA)	204
Peak Demand Load, Max Current (A)	566
PSD Total Load for 64 Doors, including All Miscellaneous Loads, (A)	165
Total Load (Station Peak + PSD), (A)	731
Station Service Power Capacity, (A)	1,200
Service Spare Capacity, (A)	469
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station (the two 7 line edges and one equipment room) is estimated to be $32.8M to install APGs and $41.3M to install PSDs (See Appendix E).

Figure 3 – Typical northbound platform edge- Queensboro Plaza Station

Figure 4– Typical southbound platform edge- Queensboro Plaza Station

1.16 Court Square Station

Summary: *Court Square Station (MR-462) is not feasible for APGs or PSDs as there is not enough area to adequately locate a PSD equipment room(s). Generally at side platform stations, equipment rooms can either be accommodated at the ends of the platforms, in back-of-house areas, or at the mezzanine level. At Court Square, the train length is as long as the platform, so a room cannot be located at the north-end of the platforms. The south end of the platforms provide connections to other lines in addition to accommodating back-of-house elements. Additionally, the mezzanine level is fully utilized and highly trafficked. Another obstacle at this station is the platform structure which is made of Fiber-Reinforced Polymer planks. Complex modifications would be required in order to allow for the installation of a PSD system.*

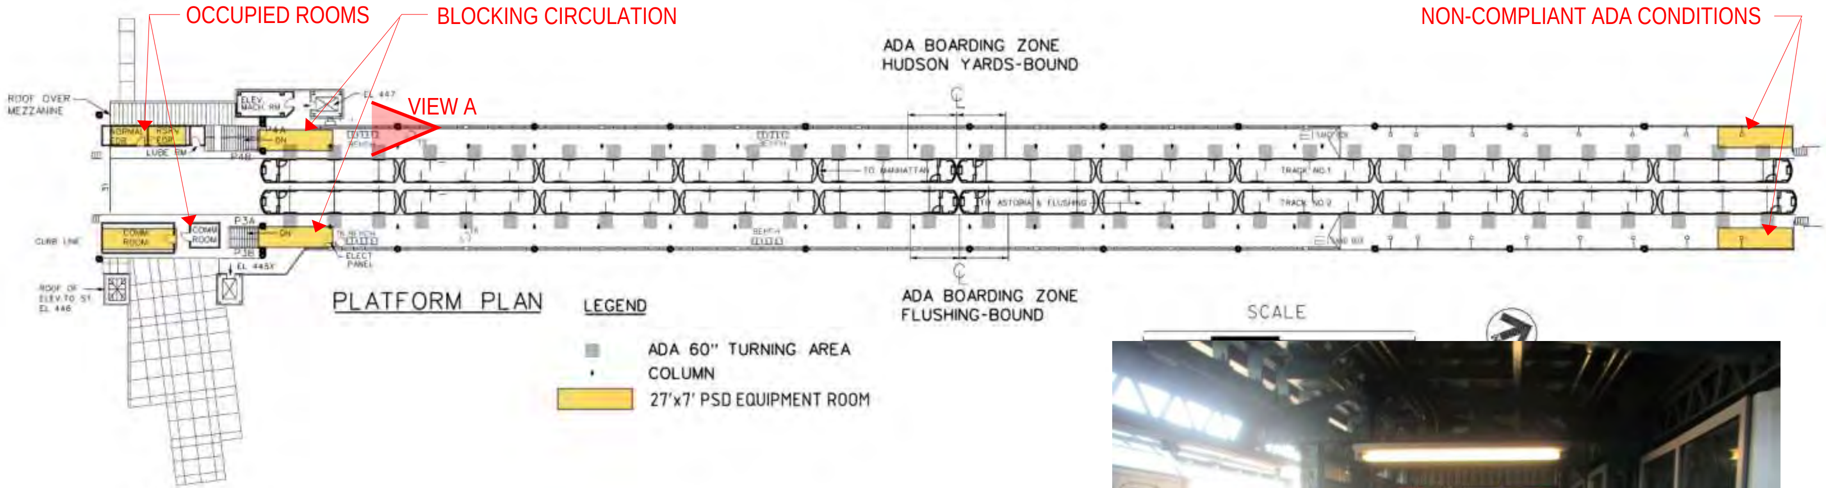
Description

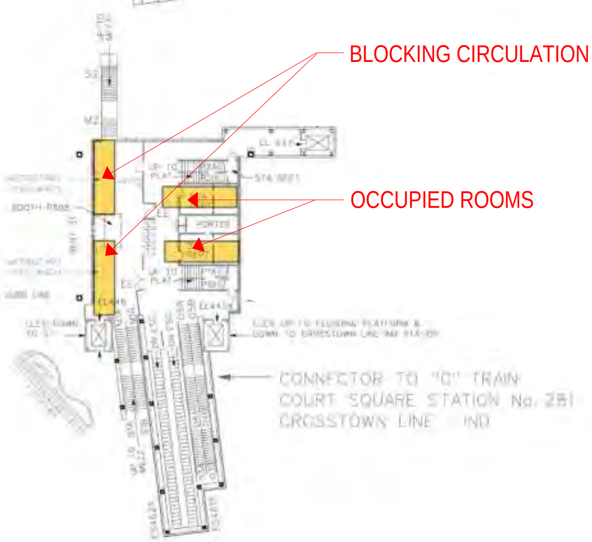
Court Square Station is an elevated station with straight side platforms. Court Square Station is a historically designated property. Typically, the platforms are approximately 12'-0" wide. The lack of space to accommodate an equipment room eliminates Court Square as a feasible station (see figure 1 on the following page).

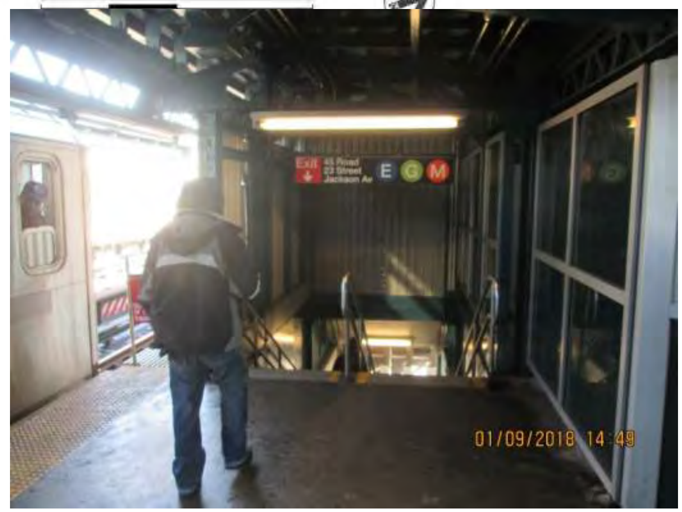
Fiber-Reinforced Polymer (FRP) Structure

The platform consists of a series of prefabricated FRP planks spanning perpendicular to the tracks with a cantilevered platform edge, similar to the precast concrete platforms found at elevated stations throughout the System. The FRP planks have been installed recently and are quite robust structurally. It is likely that the planks have sufficient strength to support the added weight and applied loads of a PSD system, however there would be challenges in the installation of a PSD system. Installation of the PSDs will likely require the addition of a steel or FRP edge member between the ribs of the planks in order to continuously support the PSD. The added member will also allow the PSD system to be thru-bolted to the planks and provide resistance to torsion at the edge of the cantilever. Installation of the edge member will be challenging, as the working clearances between the platform and the girder below will restrict the size of the member, tools, and equipment. The installation of conduits for power and communications would also be required. Holes for the conduits would have to be drilled through the FRP planks so the cables can be routed below the platform edge. The location of these holes must be compatible with both the FRP planks (i.e. they cannot pass through the ribs), as well as the PSD system itself, which presents a coordination challenge.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for ‘7’ (Flushing) Line Stations
(Court Square Station)







VIEW A: SOUTH-END OF PLATFORM (HUDSON-YARDS-BOUND)
CIRCULATION TO EXIT AND CONNECTIONS

Figure 1– Overall Plan highlighting lack of space for an equipment room – Court Square Station

Table of Contents

1.17 Hunters Point Avenue Station

Summary: Hunters Point Avenue Station (MR-463) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. Columns toward the platform edge which flank the stairs are 3'-6" away from the platform edge. At the stairs on the Flushing-bound platform, the 32"minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would only be 27" (see figure 1).

Description

Hunters Point Avenue Station is a below-grade station with straight side platforms. The platform structures are cast-in-place concrete. Access to the station upper mezzanine is available only at the east-end of the platforms. Platform widths vary, but are typically about 12'-0" wide. Typically, columns are spaced 15' on center approximately 3'-6" away from the platform edge. Currently at the stairs on the Flushing-bound platform, passengers walk in the clear space between the columns and the platform edge (3'-6") which complies with ADA requirements. See figure 2 for the location of this non-compliant condition at Hunters Point Avenue Station.

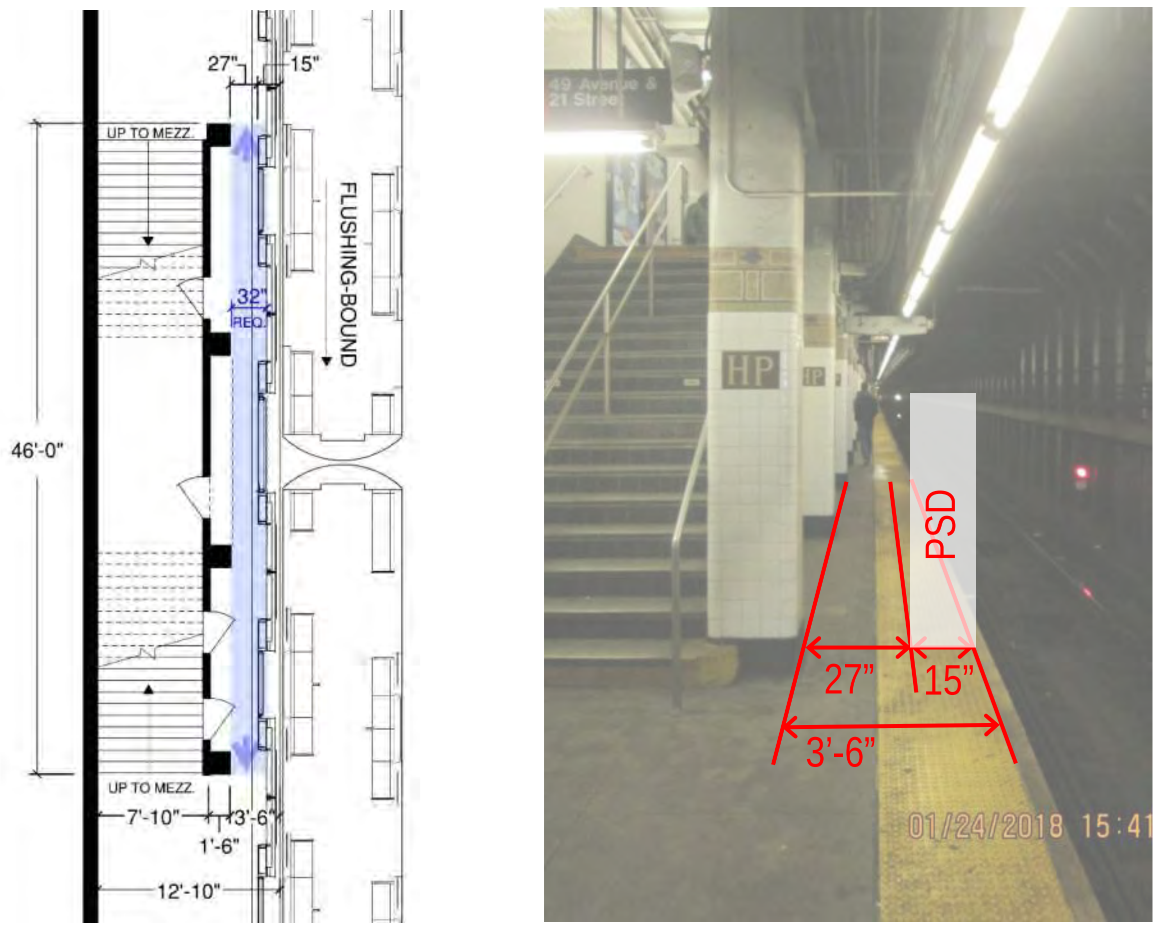


Figure 1 –ADA constraint at Flushing-bound stairs and photo of condition- Hunters Point Avenue Station

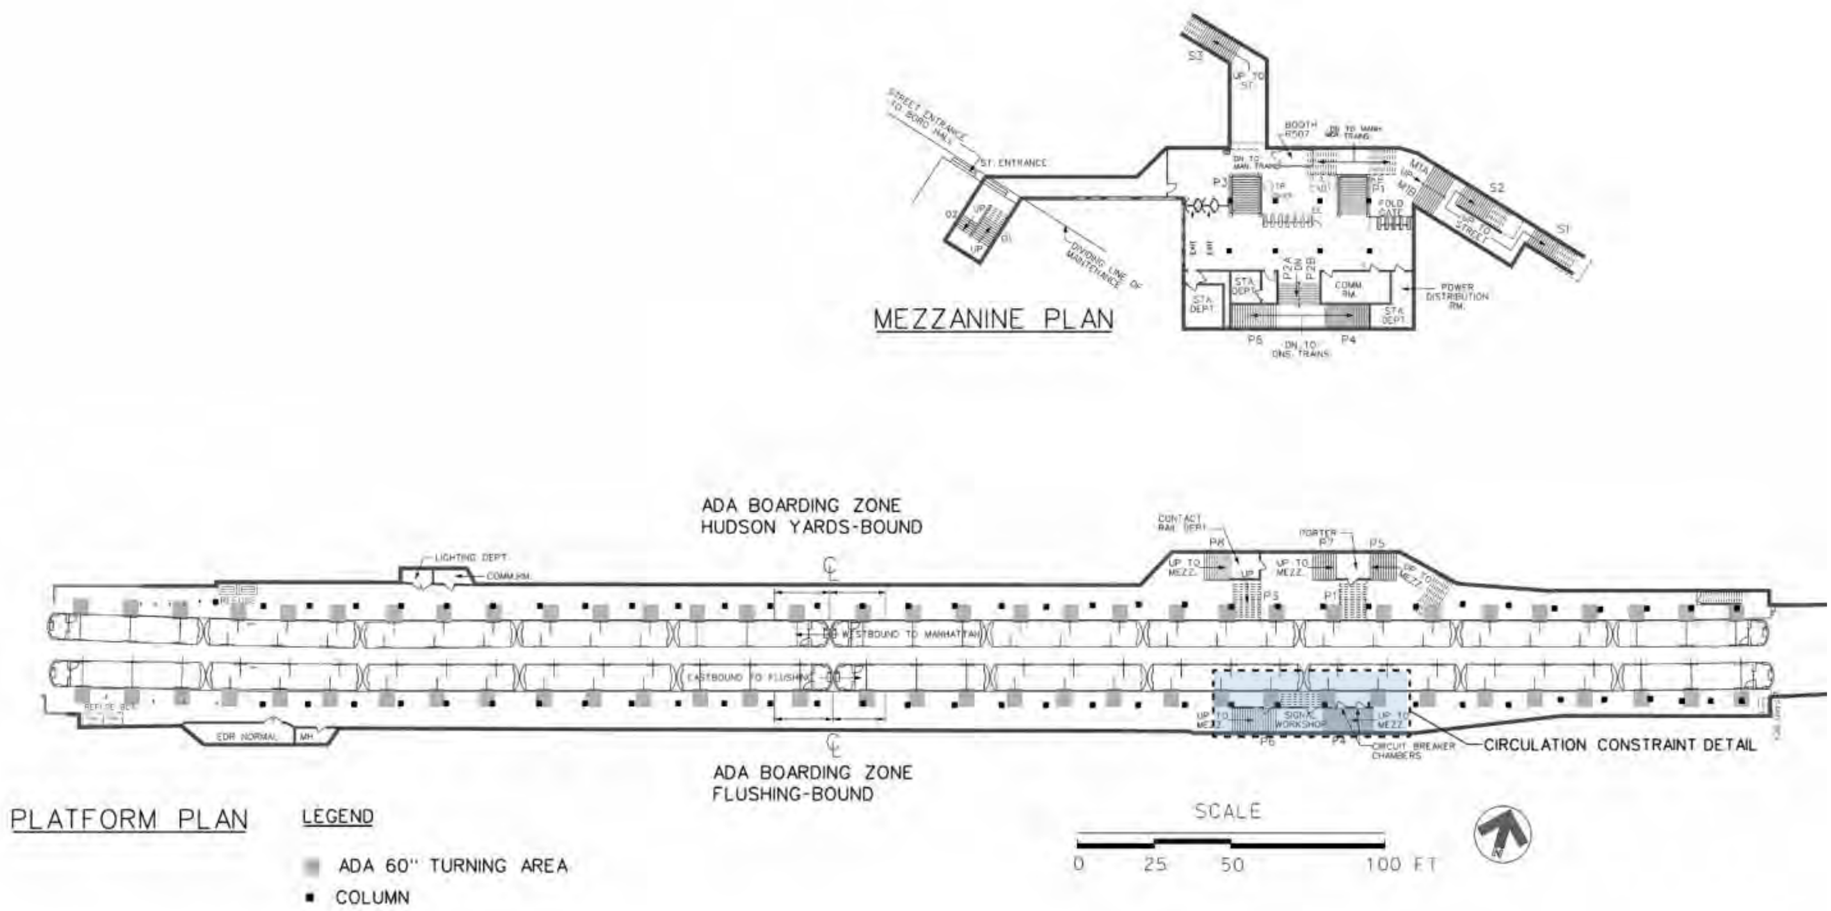

Figure 3 – Station Plan- Hunters Point Avenue Station

1.18 Vernon Boulevard-Jackson Avenue Station

***Summary:** Vernon Boulevard-Jackson Avenue Station (MR-464) is feasible for both APGs and PSDs. On both platforms, there is a column in front of an ADA-designated door. These existing non-compliant conditions would not be exacerbated in the implementation of a platform edge barrier. As the platform edge has been recently renovated, platform structural work would only be required for an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Vernon Boulevard-Jackson Avenue Station is a below-grade station with straight side platforms. The platforms are made of cast-in-place concrete and can be accessed from the street. For a plan of Vernon Boulevard-Jackson Avenue Station, see figure 1. Back-of-house elements are placed primarily on the eastern end of the platform or in the control areas. The platforms are approximately 11'-0" wide with columns spaced 15'-0' on center. Column faces are typically 4'-0" from the edge of the platform. Ceiling heights range from 8'-6" to 9'-6" at the edge of the platform. There are multiple conduits over the platform edges, with a larger number at and beyond the Hudson Yards-bound platform edge. See figure 3 for a typical platform view at this station.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. There is conduit below the Flushing-bound platform edge that would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

One room can be located at the east-end of the station at the Flushing-bound Jackson Avenue entry. There is a large landing within the paid area that is a few steps above the platform level. There is currently a barricade in this location, the equipment room measuring approximately 7' x 27' can be accommodated in its place (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 1.5. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

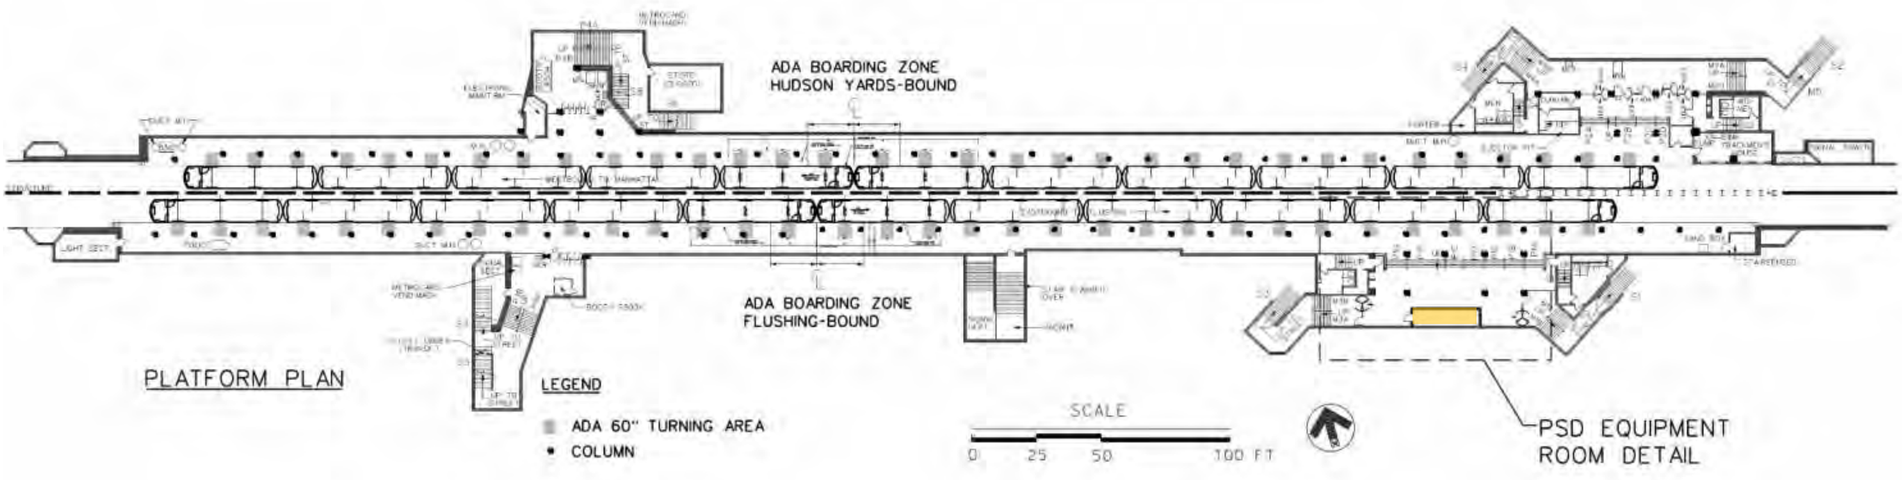

Figure 1 – Station Plan- Vernon Blvd.- Jackson Ave. Station

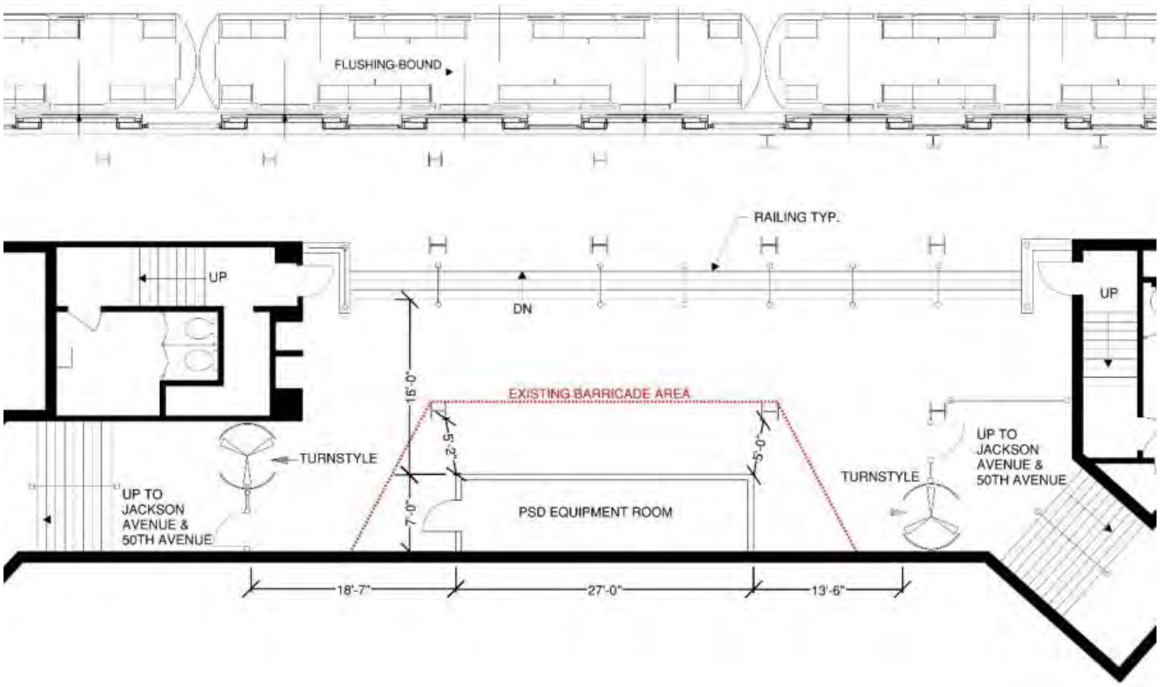

Figure 2 – PSD Equipment Room Detail - Vernon Blvd.- Jackson Ave. Station

Platform obstructions within 5' of edge:

Hudson Yards-bound: Most columns are 48" from the platform edge, however there are a few that are 24" from the platform edge. One column is in front of an ADA-designated door, however the implementation of a platform edge barrier would not exacerbate this already non-compliant condition.

Flushing-bound: Most columns are 48" from the platform edge, however there are a few that are 24" from the platform edge. One column is in front of an ADA designated door, however the implementation of a platform edge barrier would not exacerbate this already non-compliant condition.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table on the following page. Calculation is based on APG loads which are the most demanding.

Flushing Line Station Electrical Capacity Analysis	
NYC T Station MR Number	464
Station Name	Vernon Blvd - Jackson Ave
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	160
Apparent Power (kVA)	200
Peak Demand Load, Max Current (A)	555
PSD Total Load for 64 Doors, including All Miscellaneous Loads, (A)	165
Total Load (Station Peak + PSD), (A)	720
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	80
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.9M to install APGs and $41.2M to install PSDs (See Appendix E).

Figure 3 –Typical Platform Condition- Vernon Blvd.- Jackson Ave. Station

1.19 42nd Street-Grand Central Station

Summary: 42nd Street-Grand Central Station (MR-465) is feasible for both APGs and PSDs. There is an existing non-compliant ADA condition at one of the ADA-designated doors on the Hudson Yards-bound platform. This existing non-compliant conditions would not be exacerbated in the implementation of a platform edge barrier. There are a few ceiling-mounted conduits which follow the full arch of the ceiling, extending over both tracks. The locations of the conduits would have to be coordinated in the implementation of full height PSDs. As the platform edge has been recently renovated, platform structural work would only be required for an APG system (see structural report; Appendix B). It is assumed that existing power is adequate.

Description

42nd Street-Grand Central Station is a below-grade station with one center/island platform (see figure 1 for a plan of the station). The Hudson Yards-bound track is straight, while the Flushing-bound track is slightly curved at the west-end of the station. The platform structure is made of cast-in-place concrete. The platform is accessed from an upper level Mezzanine. Back-of-house elements are located at either end of the platform and on the mezzanine level. The platform is column free with the exception of four columns against the centrally located stairs towards the Hudson Yards-bound platform edge. The platform width varies, but typically is approximately 18'-6" wide. The ceiling is arched with a vertical clearance of 12'-0" at the platform edge.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. As noted in the summary, ceiling-mounted conduit would have to be coordinated or rerouted as they extend over the full span of the station (see figure 4).

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Both hung and wall-mounted conduits below the platform edge would need to be relocated to accommodate the requirements of the APG system.

Equipment Room

An equipment room can be accommodated at the west-end of the platform. The proposed room dimension is 27'-0" x 7'-6" (see figure 2).

Track Layout

The Hudson Yards-bound track is tangent. The Flushing-bound tack is mostly tangent, but is mildly curved and the west-end of the station. Thus, we are only expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs at the west-end of the Flushing-bound track. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

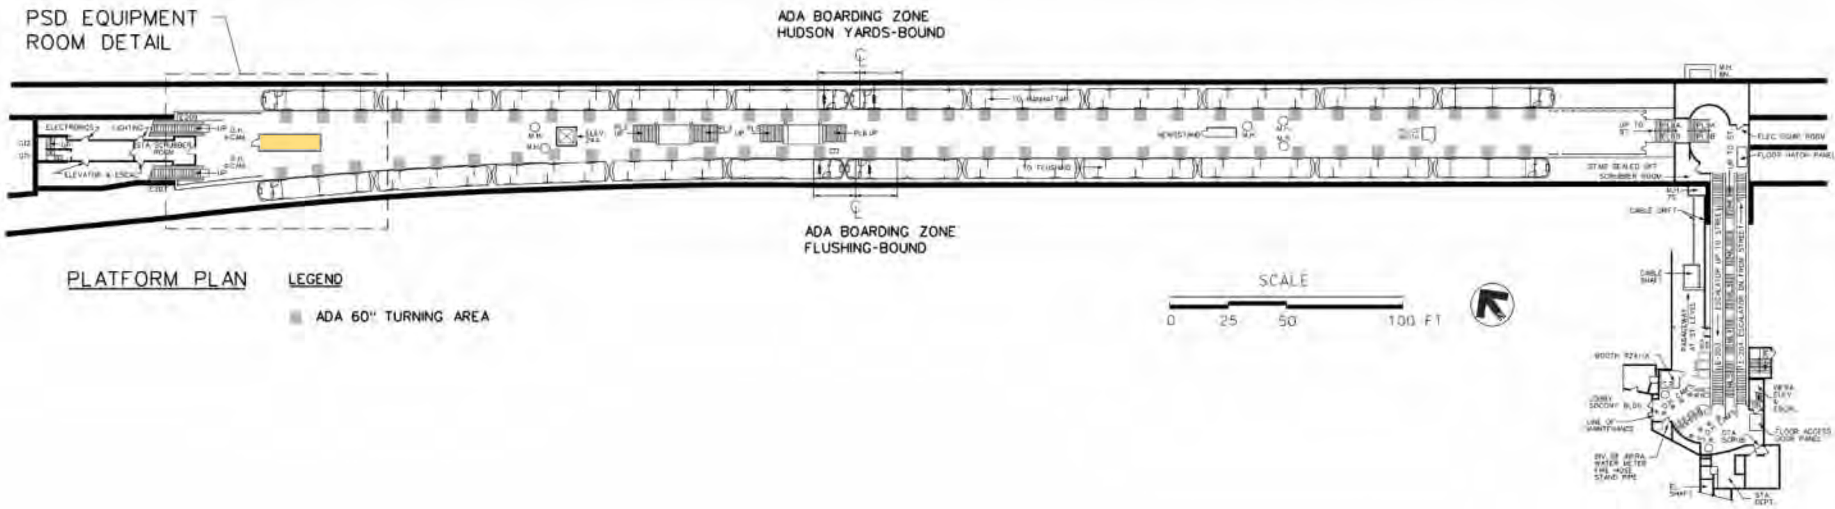

Figure 1 – Station Plan- 42nd Street- Grand Central Station

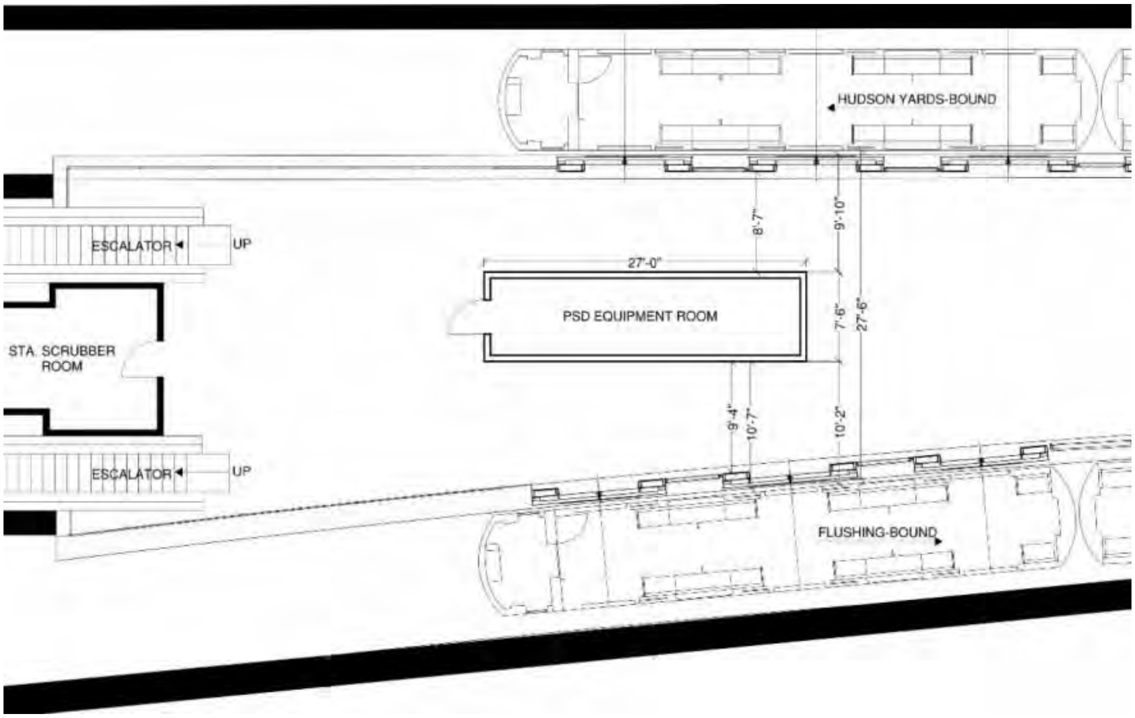

Figure 2 – PSD Equipment Room Detail – 42nd Street- Grand Central Station

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 3. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

Platform obstructions within 5' of edge:

Hudson Yards-bound: The four centrally located stairs are 5'-4" away from the platform edge, with columns 4'-7" away from the platform edge. One of these columns is in front of an ADA-designated door, however the implementation of a platform edge barrier would not exacerbate this existing non-compliant condition.

Flushing-bound: None

Lighting:

Existing lighting: In some locations, linear fluorescent lighting is used and is located approximately 24" from platform edge (see figure 3). Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration. At other parts of the station, lighting is further away from the platform edge and arranged forming diamond shapes at the middle part of the platform (see figure 4).

Power:

This information was not ascertainable at the time of the survey. However, we do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $33.1M to install APGs and $41.5M to install PSDs (See Appendix E).

Figure 3 – Typical platform view adjacent to central stairs – 42nd Street- Grand Central Station

Figure 4– Typical platform view looking towards the end of the platform ends – 42nd Street- Grand Central Station

1.20 5th Avenue-Bryant Park Station

Summary: *5th Avenue-Bryant Park Station (MR-466) is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. Columns toward the platform edge which flank the stairs are 3'-10" away from the platform edge. At all stairs along the length of the platform, the 32" minimum requirement for ADA compliant wheelchair movement would not be met as the remaining circulation width would be 31" (see figure 1). At the stairs, clearances along both platform edges would not comply with the required minimums.*

Description

5th Avenue-Bryant Park Station is a below-grade station with a slightly curved center/island platform. The cast-in-place concrete platform is accessed by 5 centered stairways and one stairway on the western end of the platform (see figure 2). Column spacing along the platform is approximately 15' on center with column faces 3'-10" to the edge of the platform. The platform is approximately 17'-8" wide, but tapers to a narrow 9'-2" at the east-end of the platform. Currently at all stairs along the length of the platform, passengers walk in the clear space between the columns and the platform edge (3'-10") which complies with ADA requirements. The implementation of a platform edge barrier would result in non-compliant ADA conditions that would not allow for ADA compliant wheelchair movement along the length of the platform.

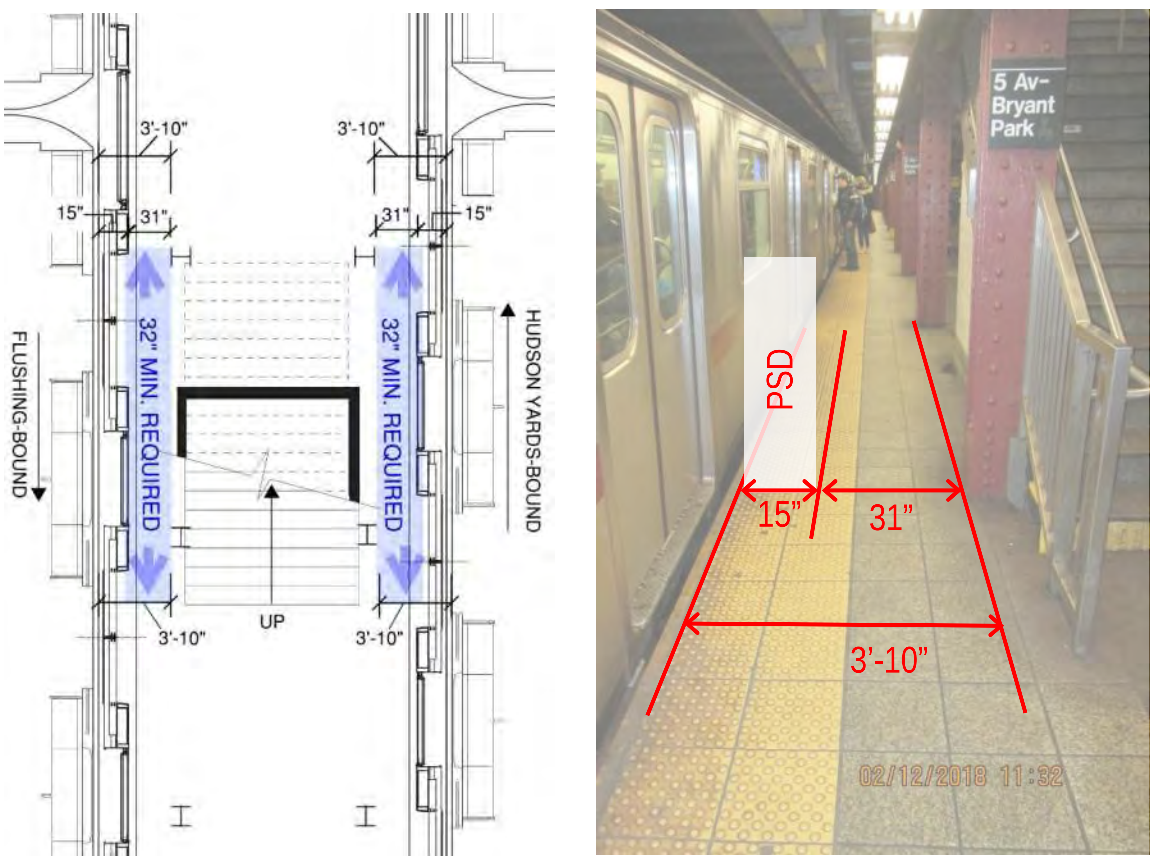

Figure 1 – Typical constraint at all stairs and photo of existing conditions- 5th Avenue-Bryant Park Station

Table of Contents

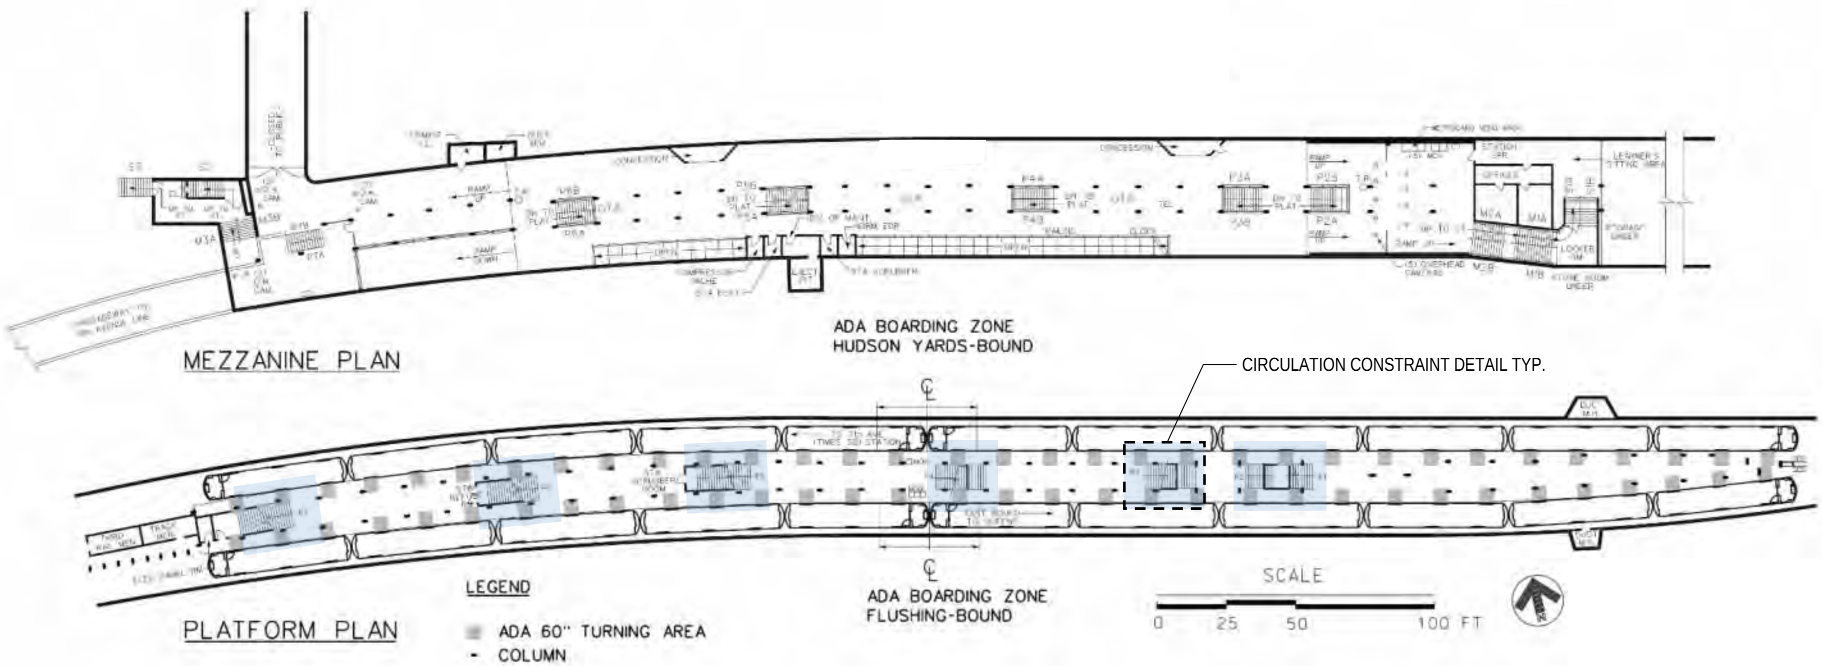

Figure 2 – Station Plan- highlighting constrained areas at all stairs- 5th Avenue-Bryant Park Station

1.21 42nd Street-Times Square Station

Summary: 42nd Street-Times Square (MR-467) is feasible for both APGs and PSDs. At both platform edges, there is one train signal box with a vertical clearance less than 7'-0" which would have to be relocated in the implementation of a full height PSD system. As the platform edge has been recently renovated, platform structural work would only be required for an APG system (see structural report; Appendix B). Existing power is adequate.

Description

42nd Street-Times Square Station is a below grade station with a straight center/island platform. The cast-in-place concrete platform is accessed at various locations along the length of the platform. Back-of-house elements are located at the ends of the platform as well as at the mezzanine level. Typically, the platform is approximately 29'-4" wide. Columns are spaced 15' on center, column faces are usually 9'-0" from the edge of the platform. Vertical clearances vary at different parts of the platform. Towards the western-end of the platform, vertical clearance lowers from 8'-2" to 7'-0". There are many conduits over the platform, with less over the platform edge. See figure 1 for the 42nd Street-Times Square station plan and figure 3 for a typical platform edge view at this station.

Full Height PSDs: As indicated in the summary, coordination/relocation of train signal boxes would be required in the implementation of a full height system. Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

*Half Height PSDs (aka APGs)***:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting. Wall-mounted conduit below the platform edges would need to be coordinated to accommodate the requirements of the APG system.

Equipment Room

One room can be accommodated on the lower mezzanine next to the scissor lift storage room. The proposed room dimension is approximately 26'-6" x 7'-0" (see figure 2).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, structural work would only be required for the installation of an APG system. The 2012 NYCT conditions survey gave the platform edges an average rating of 2.25. On a scale of 1 to 5, a rating of 1 indicates no apparent deterioration and 5 indicates that the observed deterioration will require immediate repair.

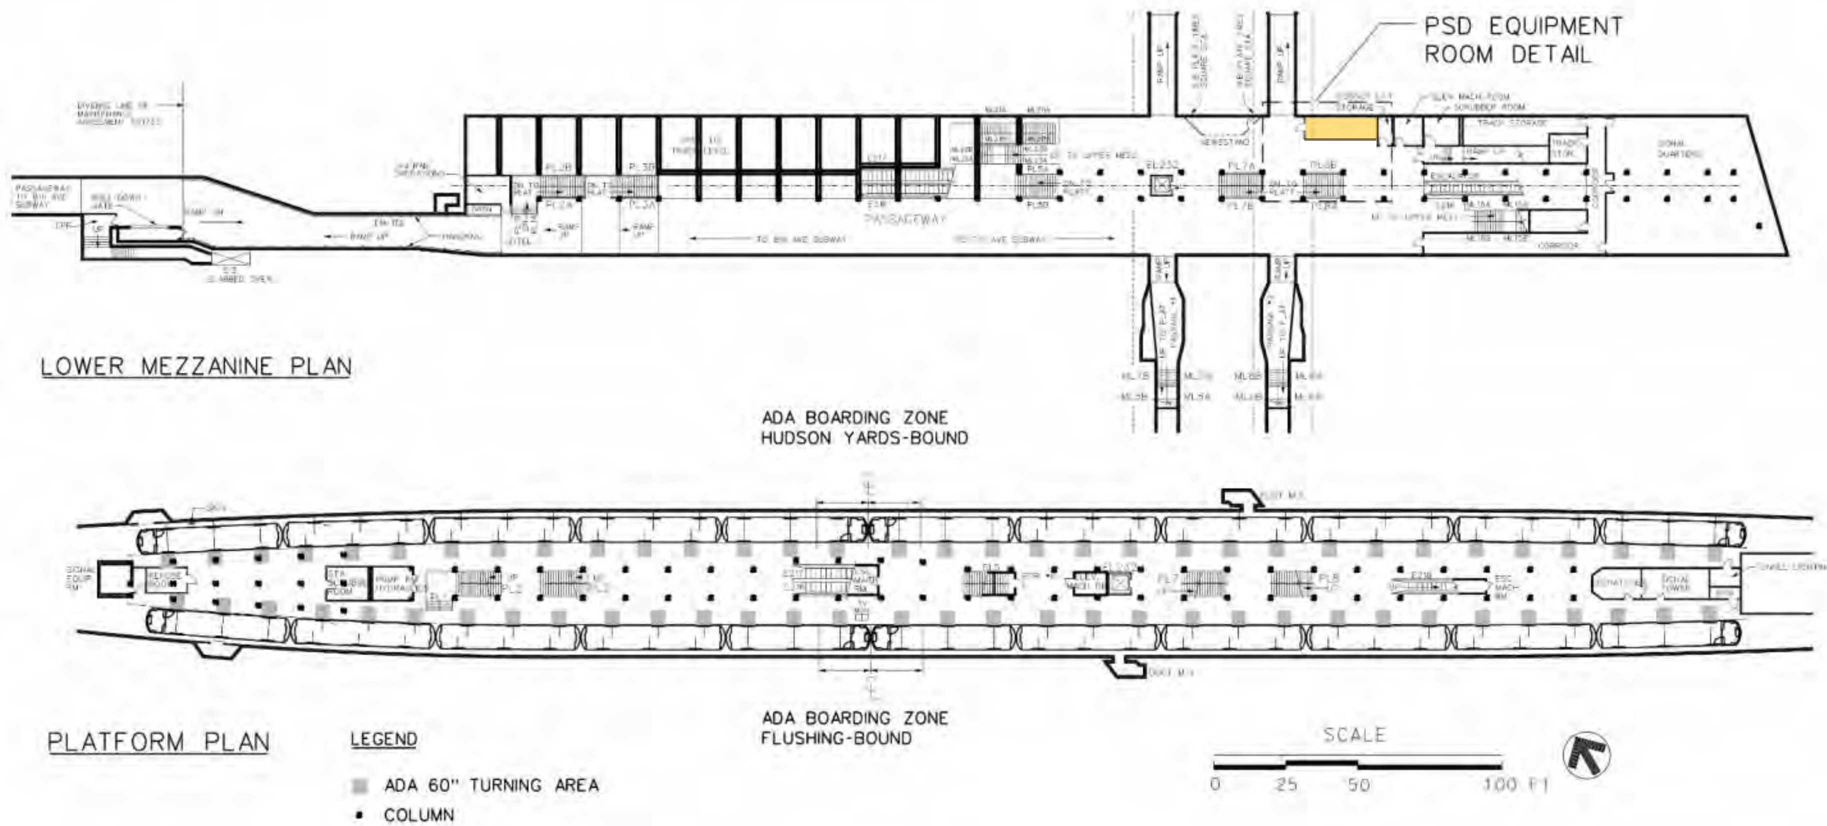

Figure 1 – Station Plan- 42nd Street-Times Square Station

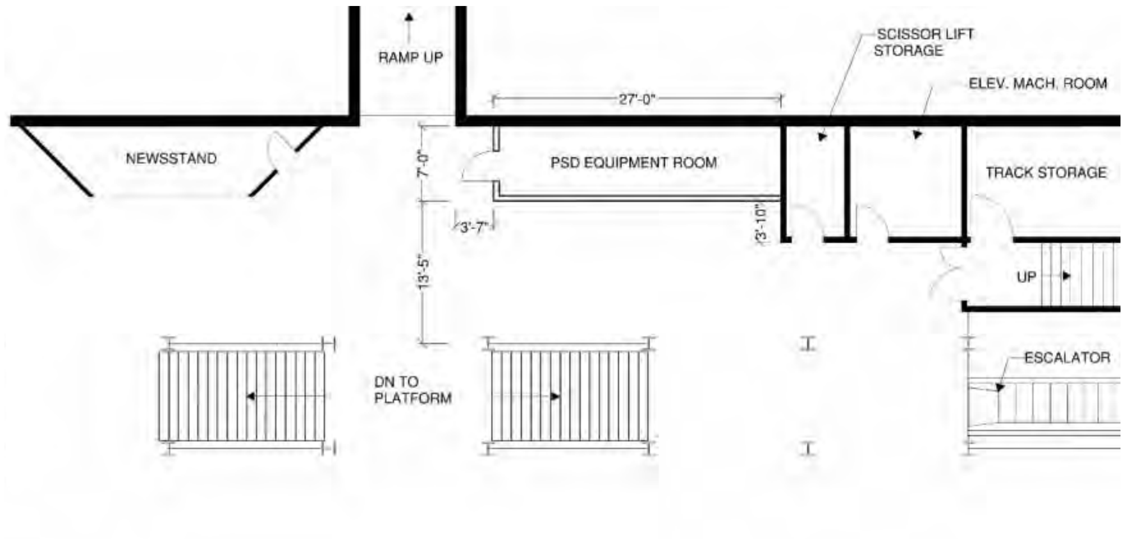

Figure 2 – PSD Equipment Room Detail - 42nd Street-Times Square Station

Platform obstructions within 5' of edge:

Hudson Yard-bound: Five columns on the western side of the station are 30" from the platform edge. Four of these columns are currently in front of train doors, however the implementation of a platform edge barrier would not exacerbate these existing conditions.

Flushing-bound: Five columns on the western side of the station are 30" from the platform edge. Two of these columns are currently in front of train doors, however the implementation of a platform edge barrier would not exacerbate these existing conditions.

The use of 22" emergency egress hinged doors are impeded by approximately 1 existing column (total on both platforms).

Lighting:

Existing lighting: Linear fluorescent; approximately 12" from platform edge with a vertical clearance of 8'-2". Depending on the specific APG / PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table on the following page. Calculation is based on APG loads which are the most demanding.

Flushing Line Electrical Power Capacity Analysis	
NYC T Station MR Number	467
Station Name	42nd St - Times Square
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	94
Apparent Power (kVA)	118
Peak Demand Load, Max Current (A)	328
PSD Total Load for 64 Doors, including All Miscellaneous Loads, (A)	165
Total Load (Station Peak + PSD), (A)	493
Station Service Power Capacity, (A)	2,000
Service Spare Capacity, (A)	1,507
Electrical Service is Adequate or Not	Yes

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.4M to install APGs and $38.8M to install PSDs (See Appendix E).

Figure 3 – Typical platform edge condition- 42nd Street-Times Square Station

Table of Contents

1.22 34th Street-Hudson Yards Station

Summary: 34th Street-Hudson Yards Station (MR-471) is feasible for both APGs and PSDs. As there are no columns along the length of the station, there are no ADA obstructions. While the 34th Street-Hudson Yards station is newly constructed, platform structural work will be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.

Description

34th Street-Hudson Yards Station is a below-grade station with a straight center/island platform. As the terminating station in Manhattan, the two tracks serve Flushing-bound trains. There are eight stairs at multiple locations along the length of the platform providing access from the mezzanine level. The platform structure is made of cast-in-place concrete. Back-of-house elements are found on both ends of the platform and at the mezzanine level. The mezzanine is sleek, featuring curved walls and ceilings. See figure 1 for the platform plan and possible room locations.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs): This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, entrapment prevention sensors may be ceiling-mounted or on the APG unit itself. In any case, there will be CCTV cameras over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

Two rooms can be symmetrically located beneath the stairs at the west and east-end of the platform. Both rooms will measure approximately 7'-6" x 27'. As both conditions are very similar, see figure 2 for a representation of the location for both equipment rooms. In order to maintain the sleek look on the mezzanine and minimize visual impact on the platform, the equipment rooms can be tucked below stairs at towards the ends of the platform (see figure 3 for an image of this condition).

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform edge condition

As the construction of this station was completed in 2015, structural work would only be required for the installation of an APG system. As this station was only completed in 2015, the platform edge was not scored in the 2012 NYCT conditions survey.

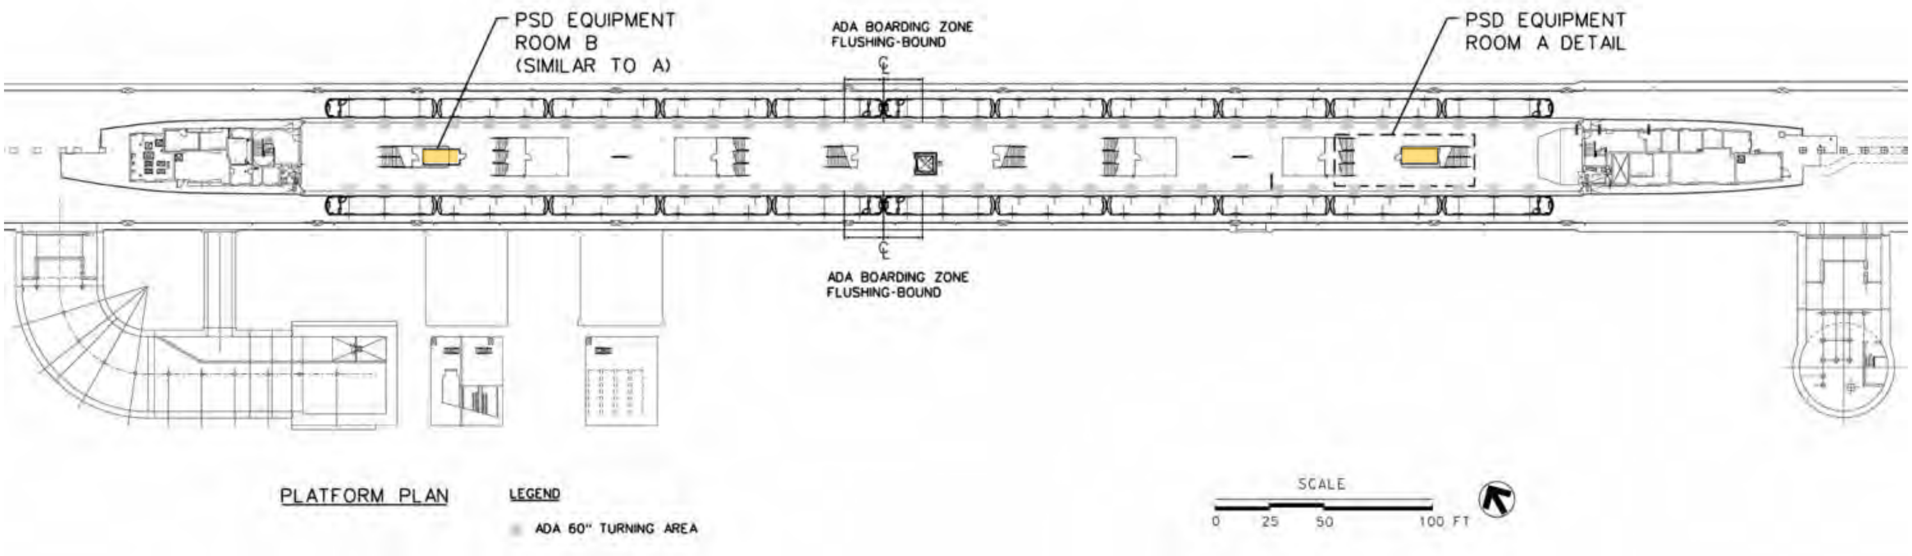

Figure 1 – Station Plan- 34th Street- Hudson Yards Station

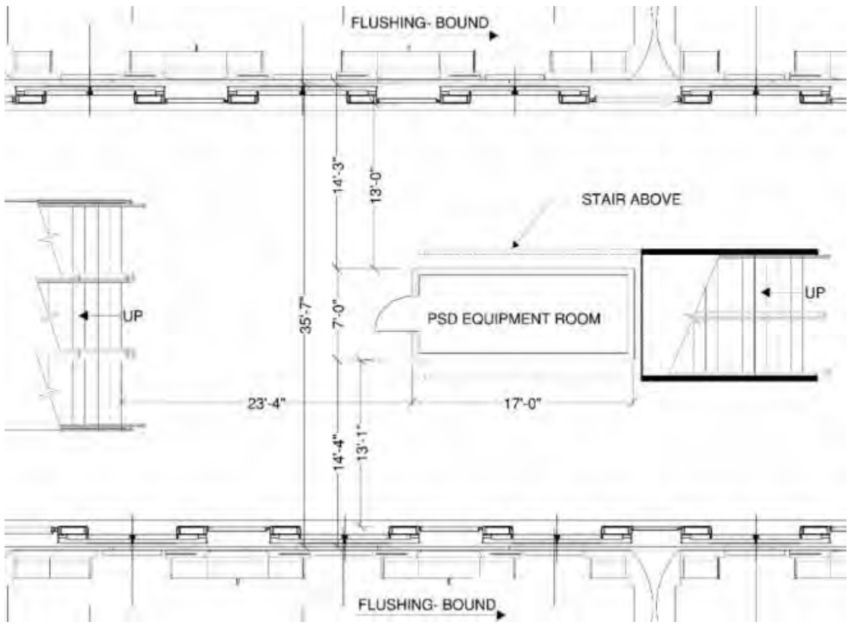

Figure 2 – PSD Equipment Room Detail (similar conditions at both rooms) -34th Street- Hudson Yards Station

Platform obstructions within 5' of edge:

Flushing-bound: No obstructions within 5' of the edge.

Lighting:

Existing lighting: Linear fluorescent; approximately 24" from platform edge. Depending on the specific APG / PSD design used, there could be no or minimal alternations to the existing lighting configuration.

Power:

Power is adequate. See Electrical table below. Calculation is based on APG loads which are the most demanding.

Flushing Line Station Electrical Capacity Analysis	
NYC T Station MR Number	471
Station Name	34th Street - Hudson Yards

Appendix A: Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

1.0 Executive Summary

This Technology Assessment was first submitted to NYCT as part of the first Line report that recommended the location of the Pilot PSD installation. It is included in the Line reports that follow as an Appendix for reference in the series of Line reports that will make up the System-wide Feasibility Study analyzing the challenges to be met, modifications required, and rough order of magnitude cost associated with the integration of automated fall protection into the existing NYC Transit system. This system-wide study will be performed over the coming months and years.

To quote from our scope of work for this system-wide study:

> ***1.0*** *The study will employ a hierarchical approach to assess the feasibility of installing Platform Screen Doors (PSDs), Automatic Platform Gates (APGs) or Rope Platform Screen Doors (RPSDs) via development of a screening criteria that defines 'fatal flaws' and/or critical cost factors. These screening criteria shall be recorded . . . for future reference.*
>
> ***1.1*** *Feasibility criteria addressed in Tier 1 screening will include the mix of cars classes at a given platform edge and the feasibility of PSD/APG/RPSDs given the mix of car door locations.*
>
> ***1.2*** *For subway stations and platform edges that pass Tier 1 screening, subsequent feasibility criteria for Tier 2 Stations' screening will include the following:*
>
> a. *Column location in relation to the platform edge*
> b. *Platform edge clearance adjacent to stairs and other impediments*
> c. *Impacts to ADA path of travel and boarding areas*
> d. *Conflicts of PSD/APG/RPSDs with Signals cables*
> e. *Sufficient platform width*
> f. *Extreme non-tangent track*
>
> ***1.3*** *For subway stations and platform edges that pass Tier 2 screening, subsequent feasibility criteria for Tier 3 Stations will include the following:*
>
> a. *Structural capacity of platforms to accept PSD/APG/RPSDs*
> b. *Feasibility & location for PSD/APG/RPSDs equipment room*
> c. *Confirmation of adequate power for PSD/APG/RPSDs*
> d. *Preliminary screening for the need to perform computational fluid dynamics (CFD) modeling for a given station due to existing conditions.*
> e. *Determination of communications requirements, availability and cost*
> f. *Determination of gap detection and entrapment avoidance technology requirements*
> g. *Determination of light fixture or other conflicts due to existing conditions*
>
> ***1.4*** *The scope will include field surveys of all stations and platforms that pass Tier 1 screening, as required.*
>
> ***1.5*** *A feasibility report that compiles all findings, including recommended technology(s) and rough order of magnitude estimates for Tier 3 stations will be provided on a Line by Line basis.*

2.0 Technology Overview

Platform screen doors (PSDs) and automatic platform gates (APGs) are permanent glazed barrier systems erected along the edge of a platform. Rope Platform Screen Doors (RPSDs) are horizontal cable barrier systems that raise and lower at the platform edge. These systems and solutions provide numerous benefits to the subway system including increased safety, reduction of track fires, potentially improved operations and

a customer focused user experience. While there are many benefits, there are also challenges including entrapment, berthing and additional complexity to the subway system.

There are common advantages, challenges to overcome and disadvantages to introducing platform edge barrier technologies into an existing subway system that was never designed for such technology. A simple analogy to the challenge of installing these barriers is to look at New York City before cars and after cars. The introduction of cars changed the way the streets were designed. The downtown area has narrow winding streets with tight vehicle lanes, even one way, where cars squeeze through the concrete canyons. Midtown has wide streets and avenues with multiple lanes for driving and parking. Midtown was designed for the technology, where downtown was not. This effort seeks to put a new safety technology into crowded stations designed over 100 years ago for a lower population and less frequency.

Listed below are the common advantages and disadvantages of these systems. The types of systems and their individual Pros and Cons are identified in the following sections of this chapter.

2.0.1 Platform Edge Barrier Systems

Pros

a. Eliminates the possibility of customers being pushed off the platform.
b. Reduces the possibility of suicide. Effectiveness diminishes as the height of the barrier system reduces.
c. A reduction in track fires from less debris being thrown on the tracks. Effectiveness diminishes with lower heights and opacity of barrier system.
d. There will be a significant reduction in illegal track access.

Cons

a. Space constraints, due to layout of station including potential column interferences and platform widths, must be reconciled with the Americans with Disabilities Act (ADA) and Building Code of NY State (BCNYS) requirements.
b. Requires sufficient space for barrier system electronic control equipment and/or a new control room if space is not available in existing station communication room(s).
c. New maintenance requirements of a new electro-mechanical system (most of it can be done from the platform) including cleaning of the trackside glass, cleaning of the gap detection sensors, routine belt replacement, etc.
d. Requires structural capacity to accept selected cantilevered barrier system. Some stations may require remediation work to reinforce the platform edges.
e. Requires sufficient electrical power and sufficient bandwidth for RCC monitoring.
f. Station maintenance from the trackside must be performed through barrier openings.
g. Will increase the time needed for station cleaning.
h. Interference with police radio coverage from antennas on the track wall will require additional study and potentially increase antenna installations.
i. Passengers currently have 100% availability to the subway car doors. When there is a fault in the system or a mechanical breakdown (reportedly rare at other agencies), there will be a reduction in access to the car doors.

j. Grounding requirements include the need to paint columns within arm's reach of the platform barriers with a non-conductive coating, similar to vinyl ester, to reduce stray voltage touch potential.
k. Lighting directly above the platform edge will likely need to be relocated to accommodate structure and overhead gap detection devices.
l. Other cabling/conduit under the platform edge or elsewhere in this area will also need to be relocated.

Photo 1 – Free-standing PSDs at Westminster Station, London, UK.

2.1 Platform Screen Doors (PSDs)

Physical Characteristics

Platform screen doors are tall, vertically glazed barriers that are installed along the platform edge to separate the track way from the platform. Platform screen door systems are modularized and consist of glazed bi-parting doors, glazed fixed panels and glazed emergency exit doors with a common header on top. The header is made of aluminum or steel and houses the electro-mechanical equipment that operates the doors including the motorized drive system, controls and wiring. A single motor controls both leaves of a door opening.

The PSD assembly is typically 8'-0" tall to the top of the header. The bi-parting doors are aligned to the train doors when the car is berthed. There is a berthing tolerance in the sizing of the door opening widths, making the PSD openings wider than the car body doors. This will allow enough clearance between the two sets of doors to maintain ADA clearance requirements should the train not berth accurately.

PSDs may be cantilevered from the platform, hung from structure overhead or span from platform to overhead structure. Due to the variability of existing conditions in the NYCT system, PSDs cantilevered from the platform present the most flexible option.

There may be additional construction above the PSD header to physically separate the track-way from the platform. This is usually the case in new stations where the platform can be air conditioned or air tempered for customer comfort. In the existing NYCT system however, installation of PSDs in below grade stations should be based on design criteria developed from Computation Fluid Dynamics (CFD) modeling addressing temperature rise, ventilation and smoke control. The results may require more or less air movement above or through the PSD barrier.

PSD Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. There is a reduction of piston effect on customers. This may potentially contribute to higher train speeds entering and leaving the stations.
c. There will be a significant reduction in illegal track access.
d. The presence of the doors will allow the customers to queue up at the door locations, potentially reducing dwell time.
e. Depending upon the degree of enclosure there may be a sound attenuation benefit, reducing the sound from the trains.

PSD Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. Each below grade station requires CFD analysis.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing PSD door locations for the lines they will be designed to operate on.

Photo 2 – Automatic Platform Gates at Châtelet Station, Paris, France

2.2 Automatic Platform Gates (APGs)

APG Physical Characteristics

Automatic Platform Gates (APGs) are a lower version of PSDs. They are typically 6' high, but can be as low as 4'-6". They operate in the same way as PSDs. APGs are often used instead of PSDs at exterior stations, when the arrangement of the station or airflow requirements do not allow for an 8' tall PSD or the platform will not sustain the higher structural forces of a PSD.

APG systems are an arrangement of shorter glazed bi-parting doors with pylons on each side to house the motors and accept the doors as they operate. There are also fixed glazed panels and emergency egress doors, similar to PSDs. There are no multiple mounting options and are only secured on top of the platform. APGs generally weigh less because of their height.

There are twice as many motors on APGs than PSDs for the same amount of doors. All wiring is done under the platform edge on the track side of the doors, meaning additional core drilling through the platform.

APG Pros

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs except as may be affected by their shorter height.
c. Minimal impact on air movement and ventilation. With additional experience CFD analysis may not be required at all underground stations.

APG Cons

a. Refer to the Platform Edge Barrier Pros/Cons for additional bullet points.
b. In most respects, similar to PSDs.
c. Door locations are fixed, requiring a captive fleet of cars and consists.
d. Future subway car purchases will be required to maintain the existing APG door locations for the lines they will be designed to operate on.
e. Maintenance issues unique to APGs:
    - Double the amount of motors as PSDs (each motor operating a single leaf).
    - APGs only come with belt drive motors, which do not last as long as the screw drives available on PSDs.
    - The electrical load of the doors will increase with APGs, though the motor sizes are slightly smaller because the weight of the doors is less.
    - Cabling to connect the doors is located below the platform on the track side which may require a track outage for maintenance; additional core drills into the platform for the wiring connections; and possibly space constraints at some stations.

Photo 3 – Roped Platform Screen Doors, (closed in left image, open in right image)

2.3 Roped Platform Screen Doors (RPSDs)

RPSD Physical Characteristics

Roped Platform Screen Doors (RPSDs) systems consist of two vertically lifted panels made up of horizontal cables spanning between vertical pilasters which house the vertical structure, lifting motors and mechanisms. The vertical pilasters are spaced at 20 to 30 feet along the platform edge and when the doors are open (up) the majority of the platform edge is open to accommodate multiple doors between each pair of pilasters. With a pair of motors in each pilaster and lighter door panels there are fewer motors and likely reduced electrical loads.

Currently these systems have had limited use on rail systems in Korea and Japan. They were not included in the International Research trip and report conducted in 2016 by NYCT and STV (NYCT Contract #: C-32514, Final Report Submission: September 21, 2016).

RPSD Pros

a. No impact on air movement and ventilation, i.e., CFD analysis not required at underground stations.
b. Can accommodate multiple doors locations, car classes and consists.
c. The electrical load of the doors is lower due to reduced number of motors and weight.
d. There is no glass to clean.

RPSD Cons

a. Vertically opening RPSDs are not synchronized with bi-parting car doors. Passengers may be more likely to be caught under closing RPSDs thus requiring sensors to stop RPSDs until space below is clear, possibly resulting in delays. This may also increase the likelihood of entrapment between RSPDs and car doors.
b. Due to the sequential raising of the two RPSD panels, fingers, hands, or other objects may be caught in the roped panels as they rise.
c. Subway car doors are horizontally bi-parting, while RPSDs open vertically, potentially creating boarding and alighting hazards that are not present in bi-parting systems.
d. RPSDs do not provide pre-boarding cues to door locations.
e. Concern is raised regarding hanging and swinging from the raised roped panels
f. The horizontal cables are easily climbed when in the closed position.
g. Very limited control of objects that may be thrown on tracks.
h. Requires a minimum of approximately 10 feet clear vertical height above platform edge.
i. Does not significantly reduce or eliminate potential for debris thrown onto the tracks.
j. Does not prevent dropped items from falling on the tracks.

Based upon limited information from South Korea it should be noted that these were removed and replaced with APGs in one instance. We have not yet determined why.

While RPSDs can accommodate multiple car classes, they do not fulfill many of the original design criteria for this project and introduce new hazards that appear problematic.

PSDs and APGs have been installed in most non-American subway systems around the world with little issue. PSDs and APGs will force NYC Transit into using captive fleets on each line where they are installed. While this may be seen as a drawback to the design of new cars in the future, it will simplify the car classes and potentially, operations.

2.4 Key Factors to Technology Selection

In order to recommend a system for trial installation a number of key factors must be assessed. These include:

- Operational impact

- Adaptability to accommodate multiple car classes and train consists
- Effect on existing platform lighting often located above the platform edge
- Station ventilation
- Police Radio antennas (leaky coaxial cable)
- Conflict with Signal cables
- Electrical load
- Degree of fall protection
- Visual impact

We have summarized and graded these factors in the following matrix. The grading is somewhat subjective in that the value placed on each factor is equal. APGs appear to be the best choice for a pilot installation. However, we recommend thorough post-pilot analysis before a large system-wide roll out is undertaken.

Refer to the table on the next page.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Assessment of Platform Screen Door Technologies					
Assessment Factors		**PSDs**	**APGs**	**RPSDs**	**Grading system**
General Factors	**Specific Subfactors**				
1. Safety - What are the relative benefits of this technology to public safety?					0 - 5 (with 5 highest benefit)
	Protection to the public	5	4	1	higher the number the better
2. Capital Cost - What is the anticipated relative installation cost of this technology?					0 - 5 (with 5 lowest cost)
	Cost of technology itself	2	3	3	higher the number the better
	Cost of impact to existing station systems	2	3	2	***RPSD's have not been priced**
3. O&M Cost - What is the likely relative operations and maintencne cost of this technology?					0 - 5 (with 5 lowest cost)
	Number of motors/elements requiring service	3	2	4	higher the number the better
	Ease of cleaning glass	1	2	5	
	Ease/number of sensors requiring maintenance/cleaning	3	3	3	
4. Operations - What is the impact of the technology on current operations protocols?					0 - 5 (with 5 lowest impact)
	Extent of changes in protocol for train operations	1	4	1	higher the number the better
	Extent of changes to maintenance protocols	1	1	1	
5. Risks - What are the foreseeable risks in safety and operations of this technology?					0 - 5 (with 5 lowest risk)
	Risks to conductors	1	5	1	higher the number the better
	Risks of entrapment	3	3	1	
Raw Score		22.00	30.00	22.00	
Weighting of the Factor No.	**Weight of Each Factor**				
1.	25.0%				
2.	20.0%				
3.	20.0%				
4.	20.0%				
5.	15.0%				
Weighted Score		4.30	5.05	4.20	**Highest value is best**

Technology	**Comments**
Platform Screen Doors (PSDs) (> 8' in height)	Recommended for new underground stations; benefits air tempering and smoke control systems; not recommended for existing stations as impact to existing systems, particularly station ventilation, are too high
Automated Platform Gates (APGs) (< 6' in height)	Recommended for existing underground, open cut, and elevated stations where feasible; provides most of the benefits of PSDs with marginally lower cost and fewer impacts to existing systems and existing operating procudures
Roped Platform Screen Doors (RPSDs) (full height vertical lift rope screens)	Guillotine operation is not intuitive; risk of head injury during closing or pinching of fingers & hands; vertical lift requires additional height (10"-0" min.); technology has very limited use worldwide; horizontal cables encourage climbing

Figure 1 - Platform door technologies; comparative analysis. Note: RPSD costs are "order of magnitude" based on costs of similar systems.

3.0 Operations Issues

3.1 Berthing Control Systems

In order for the platform door system to function, the doors must only open when a train is present and accepting/discharging passengers. The majority of PSD/APG suppliers do not detect interface directly with the train but interface to an ATO (Automatic Train Operating) system or a 3rd party berthing controller. The berthing controller (or ATO system) must:

- Transmit door open/closed commands from the train to the wayside
- Verify that the train is stopped
- Verify that the train doors are aligned with the platform doors
- Monitor platform door closure, to avoid movement of train when a door is open
- Monitor for individuals trapped between the platform doors and train (required if the gap is large enough to be a concern)

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY.

Berthing controllers can be procured that integrate via CBTC, via a new dedicated onboard/wayside loop, or that are installed only on the wayside and monitor the train using sensors. A wayside only system is proposed for the pilot. This avoids modifications to all the applicable vehicles for a one station pilot, while still providing NYCT with an understanding of how well platform doors will work in NY. Status of doors will be provided to crew via indicator lights, with no automated propulsion cutout.

If, prior to this pilot, NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, initially investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Equipment on trackbed	Maybe	Probably	Maybe
Requires vehicle work	Yes	Yes	No
New wayside sensors for each platform (excluding entrapment)	0	0	8
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure. (see section 3.2)

3.2 Gap Detection Systems

Entrapment distance refers to the space between the track side of the platform door and the car door. The project team visited transit agencies in Europe and Asia where platform doors had been installed. Each agency had different train types, wayside clearance diagrams, station entering speeds and vehicle dynamic envelopes. They all differ from NYC Transit's operating criteria. Because of the conservative criteria used to establish NYC Transit vehicles' limiting line of car clearance, the entrapment distance is comparatively large and may cause life safety conditions where a person could be trapped between the train doors and PSDs.

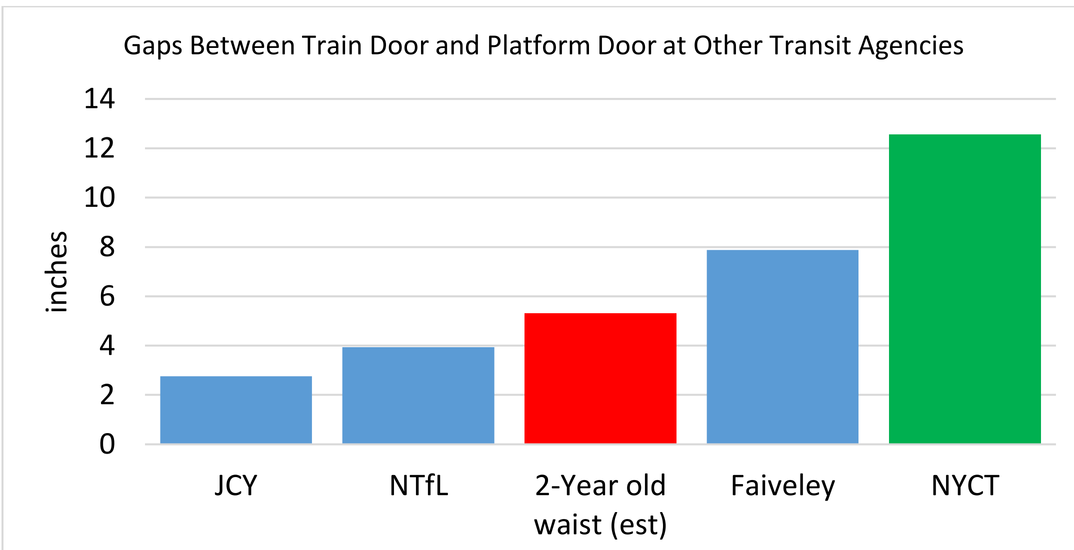

Figure 2 - Comparative gaps in various transit systems - JCY- Shanghai, NTfL - London, Faiveley - Paris

Images of Other Agency PSD Gaps

Figure 3 - Paris: no entrapment detection

Figure 4 - Paris: no entrapment detection

Figure 5 - France ATO: no entrapment detection

Figure 6 - Paris, on curve: used 3 2D scanning lasers per door

Figure 7 - Shanghai: End of platform light detection

Figure 8 - Seoul: Platform observers

Currently, NYCT has a gap at least double the recommended gap. Per the car equipment drawings for R160 (13017-03502b, sht 5 of 5, Rev b), the vehicle door is 55.4" from track centerline. Per NYCT drawing ML-CT-BT (Rev 2), the Limiting Line of Line Equipment (LLLE) ranges from 65.5" to 70.9" (depending on height of measurement) from track centerline. This provides an area of entrapment on the order of 10" to 15.5", which is greater than the recommended gap. The recommended gap is based on the size of the smallest human body which could possibly be entering the train – a toddler.

LLLE mark	Lateral distance from track CL	Height above platform	Gap between LLLE and vehicle door*
C	65.5"	0"	10.07"
D	66.8125"	27.375"	11.3825"
E	70.875"	73"	15.445"

* This gap dimension does not include any additional movement due to vehicle or track wear.

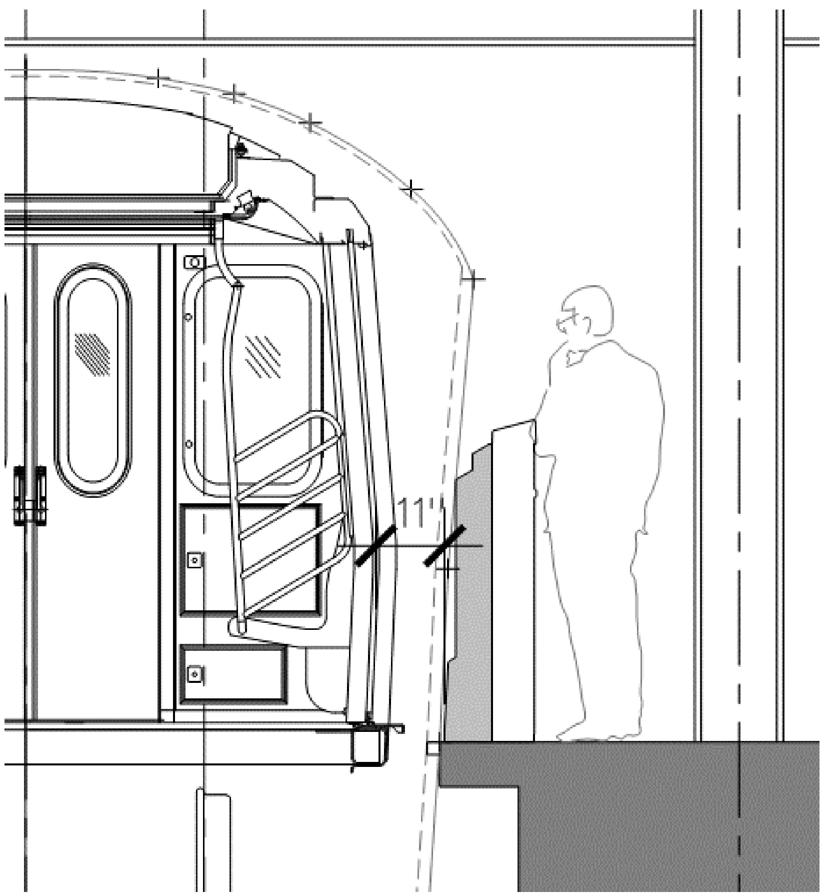

Figure 9 – Section - NYCT B-division showing Limiting LIne of Line Equipment and gap created between platform and train door

Based on our research, there are three alternative solutions to this problem. The first is gap detection where laser sensors are installed above the gap to detect obstructions. Laser detection devices need to be cleaned at least every 6 months. False detection from thrown objects, swirling newspapers, birds or lack of cleaning may create false positives and lead to train delays. Below is a calculation of reliability for detectors.

Entrapment Detection Reliability

0.02%	false detection rate per sensor per departure (per ClearSy discussion)
24	sensors per platform
0.48%	false detection rate per departure = 1 - (1- 0.0002)^24
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
70%	false detection rate for 1 platform over one day = 1 - (1- 0.0048)^249

	Impact per station
2	or fewer false detections on most days (binomial distribution 50%)
5	or fewer false detections on 95% of days (binomial distribution 95%)
71	or fewer false detections per month (on average)

Entrapment Detection+ Wayside Berthing Reliability

0.02%	false detection rate per sensor per departure (assuming same failure rate as entrapment)
32	sensors per platform
0.64%	false detection rate per departure = 1 - (1- 0.0002)^32
249	departures per day per platform (based on schedule, counted 249-318 departures/day)
80%	false detection rate for 1 platform over one day = 1 - (1- 0.0064)^249

	Impact per station
3	or fewer false detections on most days (binomial distribution 50%)
6	or fewer false detections on 95% of days (binomial distribution 95%)
95	or fewer false detections per month (on average)

Impact of Wayside Berthing System

24	more false detections per month
34%	more false detections per month

The second option is to modify the parameters that define the limiting line of car clearance that would effectively reduce the gap by moving the PSDs closer to the platform edge. This can be done by reducing the assumptions of one suspension failing and/or reducing the entering speed of the cars so that there is less rolling of the car. RATP noted that they recalculated vehicle clearances for platform screen door clearances in order to reduce the gap between the train and platform doors.

They did this by removing some of the 'excessive' criteria items due to higher speeds and multiple tolerances that were unlikely to occur concurrently.

A third recommendation would be for NYCT to have the manufacturer install rubber “bumpers” on the edge of each platform door, such that most of the gap is filled by the flexible rubber edge. This solution was employed on the Paris Metro (see photo below)

Figure 10 - Rubber bumper on leading edge of platform APG door at bottom of photo

The dynamic envelope we have been given by NYC Transit MOW restricts our ability to address entrapment with rubber bumper extensions on the leading edges of the bi-parting PSDs. To reduce the risk of entrapment enough to consider elimination of the gap detection system, we would have to extend approximately 6” into the line equipment envelope. This would leave a 5” gap between the platform and car doors allowing approximately 2” of lateral train movement before any contact is made with a moving train. While elastomeric/rubberized extensions may be effective on straight track, a combination of gap detection, CCTV and rubber extensions may be required on non-tangent platform edges. These extensions are an option that may greatly reduce the need for gap sensors and would reduce the corresponding failures and related delays. This would only be possible if the restrictions of the NYC Transit MOW dynamic envelope were relaxed.

Recommendation – Gap Detection

STV is recommending that entrapment detection be used for the pilot, and that NYCT make long-term plans to reduce the gap to less than 5" by:

- Creating a new Limiting Line of Line Equipment (LLLE) for PSD platforms, allowing a closer alignment of the train car with the platform edge.
- On new vehicle procurements, reduce the distance between the Limiting Line of Car Clearance (LLCC) and the exterior face of the vehicle door

Due to the entrapment system being fail-safe and the large number of doors to be equipped, this is expected to result in 1 to 3 departure delays per 32-door platform per day. This will require a bypass procedure to be included in the final design of the platform doors. For the pilot, install entrapment detection and camera assisted visual verification at every door.

If NYCT decides to proceed past the pilot, a plan should be put into place to modify the vehicle and wayside clearance to geometrically prevent entrapment.

3.3 Train Operations

There will be significant differences in operating procedures between the PSD, APG and RPSD systems.

With PSD and RPSD, train operators will no longer be able to open their window and visually observe the platform edge before leaving the station. They may still check monitors on the platform after first being informed by the berthing system that doors are closed and gaps are clear.

By contrast, an APG system designed to a height below the bottom of the conductor's window will permit operations to remain unchanged because the conductor will continue to be able to lean out of the window and will have full visibility forward and aft.

For the purpose of this pilot, where only one out of 24 stations on the line will have the installation, consistency of operation is essential. The APG system, designed for a height to match the bottom of the conductor's window, is therefore recommended.

For any platform doors system, train crew will still rely on the berthing system to signal that the platform doors are closed, that the gap is clear, and that the train can safely leave the station.

The new operating procedure steps are identified below as **bold/underline**:

- Train side door operation is by Master Door Controller (MDC) key and zone (front and rear) controlled.
- Side door opening operation is initiated when the Conductor (C/R) confirms that he/she is in front of the Conductor Board located along the platform at the appropriate location for the length of train in operation. The Train Operator has activated the Door Enable system (except on R32, R62 and R62A car classes), granting permission to the conductor to open the train side doors.

- **In parallel, the wayside berthing system will detect the arrival of the train. Once the train is stopped in the correct location, the PSD/APG will receive Door Enable. Doors will not yet open.**
- The C/R turns the MDC key to the "ON" position and depresses the left and right side Door Open pushbuttons, transmitting open commands to the train side doors. Train operator and conductor indication is withheld.
- **When the wayside berthing system detects that the train side doors have started to open, the PSD/APG are opened.**
- The C/R leaves the train side doors open for at least 10 seconds to afford customers sufficient time to board and alight.
- Closing is initiated by the C/R, depressing the Close pushbutton in the rear zone, followed by the Close pushbutton in the front zone.
- **When the wayside berthing system detects that the train side doors have started to close, the PSD/APG are commanded closed.**
- **When all PSD/APG are closed, the 'PSD Closed and Locked' (outside C/R and Train Operator locations) are illuminated.**
- **C/R verifies that 'PSD Closed and Locked' indication is present.**
- When all train side doors are closed and locked, C/R indication is established. T/O indication is established when the C/R turns the MDC key to the RUN position.
- **Train Operator verifies that 'PSD Closed and Locked' indication is present.**
- After the train moves, the C/R observes the platform, while the train is moving, for a distance of 75 feet. During this time he/she observe the front of train, then the rear, then the front and then closes his/her cab window.
- All passenger car side doors **and PSD/APG doors** are equipped with door obstruction sensing systems that conform to NYCT requirements for flexible and rigid object detection. On newer car fleets, local recycle and partial open features are present.
- Defective car side doors **and PSD/APG doors** may be mechanically and electrically locked out via key activation on a per panel basis. The cutting out of both car side doors in one door opening will result in a train's removal from service.
- Terminal operation is provided to leave car side doors open at the end of a run. Single panel operation **of both car side doors and PSD/APG doors** may be crew activated via the Crew Key Switch. Future provisions for dual panel opening via the Crew Key Switch are to be incorporated in conjunction with ADA requirements.
- If a train, in Two-Person Crew Operation, stops short of the appropriate station car stop sign the Train Operator must pull up for a proper station stop.
- If the train stops beyond the station limits, the C/R must apply the Emergency brakes by pulling the Emergency handle located in the cab.

- The T/O must immediately notify the RCC giving the reason for the overrun and the train crew will then be governed by RCC instructions.

4.0 Electrical Power Analysis

Below is a summary load analysis for the three Canarsie line stations, based on numbers provided for peak demand load for the three different models for which information is available.

For the purpose of assessing whether the stations' electrical service is adequate to accept the PSD & related loads, we have used the PSD system with the highest KVA load of 52.6 KVA (worst case). The PSD system 3 (Faeveley Modal APG) is therefore selected. All load numbers include power requirement for simultaneous operation of 80 doors per station. Additionally, for the Union Square Station, we have also added the load of a new escalator (as provided by NYCT), and for 1st Ave station, we have added the load of new elevators and related items (as provided by NYCT).

System Load Analysis	**PSD System 1**	**PSD System 2**	**PSD System 3**
	Based on Horton Info.	**Faiveley (Model ES2)**	**Faiveley (Model APG)**
Nominal Power (door sliding):	9.6 KW	8.1 KVA	12.1 KVA
Acceleration (See Note 1)	"Max. Sustained Power": 30.24 KW = 105A	"Acceleration": 32.3 KVA = 90A	"Acceleration": 52.6 KVA = 146A
Misc. Load related to PSD: entrapment, Comm. cabinet, berthing, AC, UPS, etc.	12 KW = 42A (0.8 PF @ 208V, 3Phase)	12 KW = 42A	12 KW = 42A
Total PSD-related Load:	105 + 42 = 147A	90 + 42 = 132A	**146 + 42 = 188A**

Note 1. The KVA load of PSD System 3 during acceleration is used as worst case load in this summary.

Appendix A – Tier 2-3 Technology Assessment (Summary of Sections 2.0 through 5.0)

Station Capacity Analysis	3rd Ave.	6th Ave.	14 St / Union Square	1st Ave.
Peak Demand Load: (last 12 months)	43 KW = 151A	72.6 KW = 252A	56 KW = 193A	38 KW = 132A
Escalator Load (See note)	N/A	N/A	200A	NA
Elevator Load (See note)	NA	NA	NA	500A
NEW Load on Station Electrical System:	188	188	200+188	500+188
Total Load	339A	440A	581A	820A
Station's Service Capacity	400A	600A	800A	800A
Notes	Elect. Service is adequate.* Service CB's to be upgraded from 300A to 400A. ConEd to rule if street feeders need to be upgraded once the Authority submits the final new loads. *400A service capacity with 339A total load leaves only 18% spare/contingency. This has been discussed with NYCT CPM and determined to be sufficient.	Elect. Service is adequate	Elec. Service is adequate	The proposed new elect. service is not adequate as currently designed under contract P-36437. The new service request will need to be revisited should these combined projects move forward.

5.0 Code Considerations

5.1 ADA – Accessible Path of Travel

Per the ADA code, there must be an accessible path of travel on the platform from one door of each train to the elevator which serves as the exit path. An accessible path involves three critical steps:

1. Achieving proper gaps between the train and the platform.
2. Providing an adequate landing on the platform to serve as a turning space in the event that there is an obstruction opposite the train door
3. Providing a pathway along the platform to the elevator. The pathway must comply with all horizontal and turning dimensions.

Accessible Door

See below excerpt from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

Subpart C-Rapid Rail Vehicles and Systems
§1192.51 General.
(c) Existing vehicles which are retrofitted to comply with the "one-car-per-train rule" of 49 CFR 37.93 shall comply with §§1192.55, 1192.57(b), 1192.59 and shall have, in new and key stations, at least one door complying with §1192.53(a)(1), (b) and (d).

Permitted Gaps

See below except from ADAAG Subpart C – Rapid Rail Vehicle and Systems:

§1192.53 Doorways.
(2) Exception. New vehicles operating in existing stations may have a floor height within plus or minus 1-1/2 inches of the platform height. At key stations, the horizontal gap between at least one door of each such vehicle and the platform shall be no greater than 3 inches.

Note: All NYCT stations being considered under this study are "existing" as defined by code. All the rolling stock is also to be considered "existing" under the code.

Throughout the system the Authority has interpreted ADA code as requiring an accessible entry at the two doors on either side of the conductor of every train. The conductor is normally placed at the center of each train. This interpretation covers all existing station platforms which undergo renovations.

Wheelchair Landings

When boarding or alighting from a train, a landing zone is established by ADA, similar to the landing in front of an elevator door. The most conservative interpretation is to require a 60" radius for turning (ADAAG 304.3.1). Alternatively, a T-shaped turning zone may be used requiring only 36" of space when exiting the train door (ADAAG 304.3.2). However, ADAAG 304.2 would suggest that the

change of elevation from the train floor to the platform must be outside the turning zone, resulting in the T-shaped space being entirely on the platform.

Obstructions to these required zones on existing platforms include columns, stair walls (ascending stairs) and stair curbs and railings (descending stairs), and miscellaneous utility rooms.

Turning Space

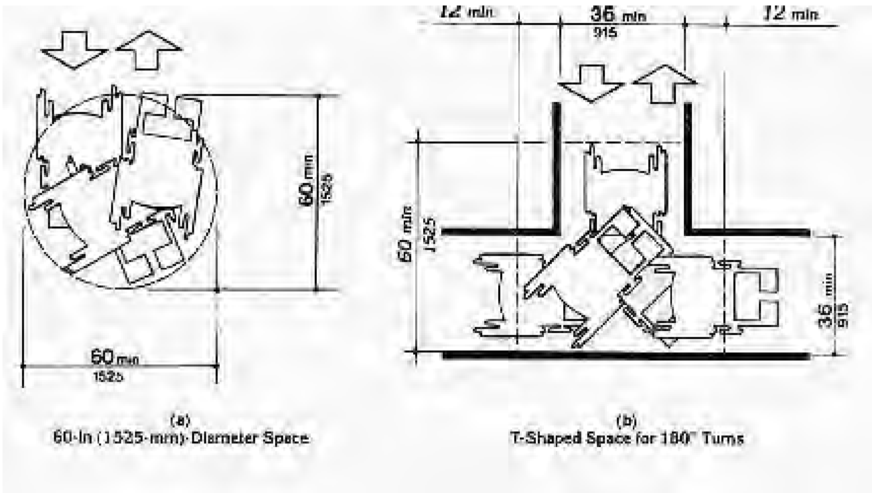
304 Turning Space
304.1 General. Turning space shall comply with 304.
304.2 Floor or Ground Surfaces. Floor or ground surfaces of a turning space shall comply with 302. Changes in level are not permitted.
EXCEPTION: Slopes not steeper than 1:48 shall be permitted.

Advisory 304.2 Floor or Ground Surface Exception. As used in this section, the phrase "changes in level" refers to surfaces with slopes and to surfaces with abrupt rise exceeding that permitted in Section 303.3. Such changes in level are prohibited in required clear floor and ground spaces, turning spaces, and in similar spaces where people using wheelchairs and other mobility devices must park their mobility aids such as in wheelchair spaces, or maneuver to use elements such as at doors, fixtures, and telephones. The exception permits slopes not steeper than 1:48.

304.3 Size. Turning space shall comply with 304.3.1 or 304.3.2.

304.3.1 Circular Space. The turning space shall be a space of 60 inches (1525 mm) diameter minimum. The space shall be permitted to include knee and toe clearance complying with 306.

304.3.2 T-Shaped Space. The turning space shall be a T-shaped space within a 60 inch (1525 mm) square minimum with arms and base 36 inches (915 mm) wide minimum. Each arm of the T shall be clear of obstructions 12 inches (305 mm) minimum in each direction and the base shall be clear of obstructions 24 inches (610 mm) minimum. The space shall be permitted to include knee and toe clearance complying with 306 only at the end of either the base or one arm.



Accessible path of travel along platform

Once a wheelchair passenger has passed over the gap, and has turned to travel along the platform to the exit point, the path of travel must have a width of 36" which may be constricted to 32" at a single point.

4.2.1 Wheelchair Passage Width*
The minimum clear width for single wheelchair passage shall be 32 in (815 mm) at a point and 36 in (915 mm) continuously (see Fig. 1 and 24(e))

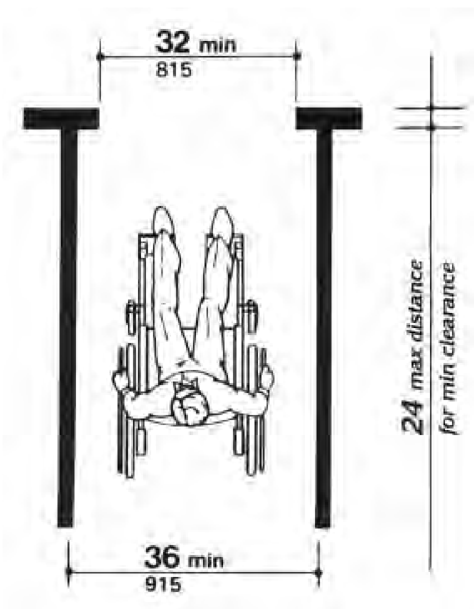


Figure 1
Minimum Clear Width for Single Wheelchair

ADA Summary

The station platforms in the entire system are defined as "existing"; hence the application of the law is often left to interpretation of the code official when it comes to incremental capital improvements to a non-compliant facility. In meetings with NYCT ADA code officials, our team came to understand the following specific application of ADA law to the NYCT system:

Columns, walls, and stairs present obstructions to disabled passengers wishing to board and alight from trains. Per direction of NYCT ADA Code Chief, these passengers must board the train at 90 degrees, and therefore must be able to execute a 90 degree turn if constrained by an obstruction near the platform edge. The applicable rule from the ADA code calls for a 60" turning radius in which to make this turn. (the "T" shape turning diagram is also applicable).

Per direction of NYCT ADA Code Chief, applicability of these standards falls into two distinct categories: the two ADA-designated doors flanking the conductor station; and the remaining 30 doors of the train. For all the doors in both categories, the alteration cannot make a dimensionally compliant condition into a non-compliant condition. For the ADA doors, if the existing condition is non-compliant, the alteration cannot make the existing clearance space more constrained than the existing. For the remaining doors, if the existing condition is non-compliant, the alteration can maintain and further constrain the non-compliant dimensions. There is no requirement to make the gap at the 30 doors compliant.

Beyond the constraints noted in the above paragraph, the NYCT ADA Code Chief noted that if a stair must be reconstructed in a new location, ADA regulations consider it an "alteration to the path of travel", requiring the construction of a fully accessible path from platform to street, i.e. new elevators, unless they are proven to be technically infeasible.

Regarding movement along the platform (parallel to platform edge), the platform edge barrier cannot preclude ADA movement where it currently exists. This is applicable even if a second parallel route exists on the other side of the platform. (An existing 32" point of constraint between the edge of platform and a column is considered a compliant passageway, even if it is less than optimal.)

ADA law requires that 20% of capital budget be directed toward ADA enhancements. Decisions on these enhancements shall be as directed by the NYCT Chief of ADA compliance.

5.2 New York State Code Considerations

By New York State law, NYCT is governed by the NYS Building Code. The specific code for existing buildings is the NYS Existing Building Code. The installation of a new wall with new doors will fall into the category of Alteration Level 2 per the NYS Existing Building Code, Section 504.

Section 504 - Alteration – Level 2
504.1 Scope
Level 2 alterations include the reconfiguration of space, the addition or elimination of any door or window, the reconfiguration or extension of any system, or the installation of any additional equipment.
504.2 Application
Level 2 alterations shall comply with the provisions of Chapter 7 for Level 1 alterations as well as the provisions of Chapter 8.

Section 701 – General
701.2 Conformance
An existing building or portion thereof shall not be altered such that the building becomes less safe than its existing condition.

Section 704 - Means of Egress
704.1 General
Alterations shall be done in a manner that maintains the level of protection provided for the means of egress.

Section 1020 – Corridors (New Building Code)
1020.2 Width and Capacity
The required capacity of corridors shall be determined as specified in Section 1005.1, but the minimum width shall be not less than that specified in Table 1020.2.

TABLE 1020.2
MINIMUM CORRIDOR WIDTH

OCCUPANCY	MINIMUM WIDTH (inches)
Any facilities not listed below	44
Access to and utilization of mechanical, plumbing or electrical systems or equipment	24
With an occupant load of less than 50	36
Within a *dwelling unit*	36
In Group E with a *corridor* having an occupant load of 100 or more	72
In *corridors* and areas serving stretcher traffic in occupancies where patients receive outpatient medical care that causes the patient to be incapable of self-preservation	72
Group I-2 in areas where required for bed movement	96

Section 705 – Accessibility
705.1.13 Extent of application
An alteration of an existing element, space, or area of a facility shall not impose a requirement for a greater accessibility than that which would be required for new construction. Alterations shall not reduce or have the effect of reducing accessibility of a facility or portion of a facility.

Section 809 – Mechanical
809.1 Reconfigured or converted spaces
All reconfigured spaces intended for occupancy and all spaces converted to habitable or occupiable space in any work area shall be provided with natural or mechanical ventilation in accordance with the International Mechanical Code.

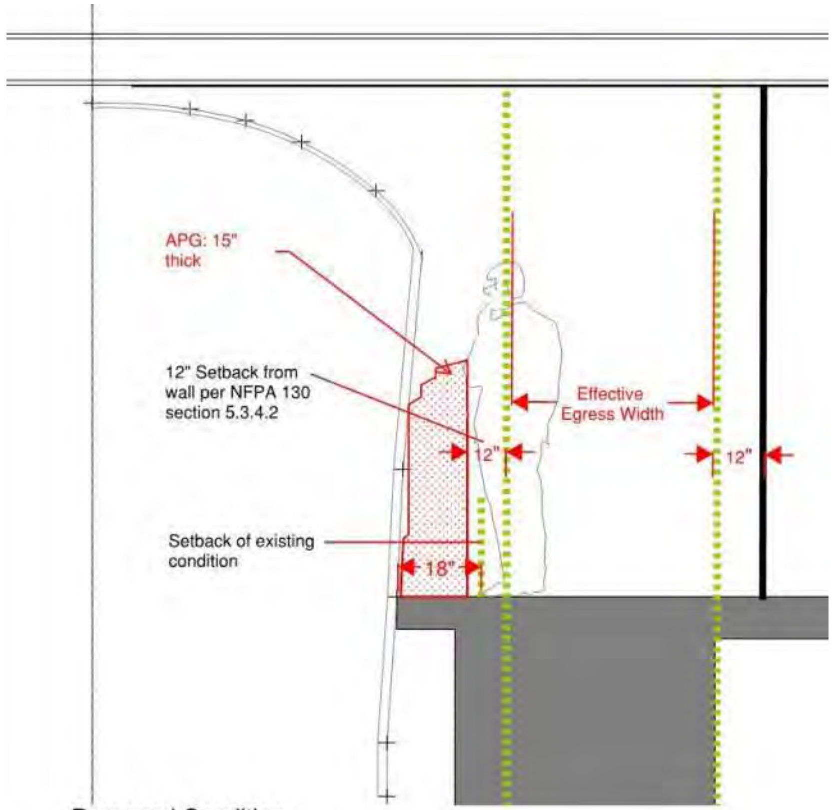
5.3 NFPA-130 (National Fire Protection Association 130 - Standard for Fixed Guideway Transit and Passenger Rail Systems)

Since the NYS Building Code does not specifically address Transit Stations, the NFPA-130 code serves to supplement the building code.

5.3.4 Platforms, Corridors, and Ramps.*

5.3.4.1 A minimum clear width of 1120 mm (44 in.) shall be provided along all platforms, corridors, and ramps serving as means of egress.*

5.3.4.2 In computing the means of egress capacity available on platforms, corridors, and ramps, 300 mm (12 in.) shall be deducted at each sidewall, and 450 mm (18 in.) shall be deducted at platform edges that are open to the trainway.



Proposed Condition
Platform edge at stair indicating effective passageway width between wall and proposed platform doors per NFPA 130

NFPA 130 can be used as a guide to the function of existing platforms as illustrated above.

5.4 General Summary of Code Issues

In the congested physical environment of the NYCT station platforms, the introduction of platform doors will further constrain numerous existing pinch points. Most of these situations are existing non-compliant code violations, built in the distant past prior to enactment of the code. However, the introduction of the platform doors, with their 15" of thickness, will reduce certain already tight clearances to dimensions below code tolerances, in some locations.

However, the situation must be evaluated in its totality. Pinch points at one side of the platform are often balanced by broad open areas on the other side of the platform such that the aggregate egress path to an exit is sufficient. Since this proposed alteration will not comply with the prescriptive code regulations, an egress analysis will be required in order to prove compliance with the intent of the code.

The installation of these platform edge barriers will constitute an Alteration Level 2. Many of the prescriptive requirements of the building code are unattainable in the existing transit station environment, requiring the processing of a variance from the NYS Existing Building Code. This variance could reference NFPA 130,

utilizing a timed analysis egress calculation, demonstrating the feasibility of egress from the platform within prescribed timeframes. The goal will be to prove that the existing non-compliant condition will not be made worse by the new construction.

ADA accessibility does not follow the above-stated logic; it cannot be looked at in its totality. Access at specific points must be provided, otherwise the facility will be non-compliant. Where the ADA-designated train doors fall adjacent to an obstruction, significant reconstruction may be required.

The wide variability of conditions that may be encountered required a detailed study of these conditions during feasibility surveys to determine which platforms / stations would best meet code requirements. After station selection a full egress analysis will serve as the basis of a variance request for approval by the State.

Berthing Report

Berthing Control System Comparison

Revision 5 – 2017-07-14

The purpose of this document is to summarize the functional needs of the berthing control system, describe what agencies and suppliers currently propose and to make an initial recommendation.

Table of Contents

Summary

Three main methods of berthing communication were considered. For a pilot, **a wayside only system is proposed as being most cost effective**.

If prior to this pilot NYCT decides it will install systems at more than 10 stations, and Siemens does not identify any showstoppers, investing in the CBTC upgrades becomes more cost effective.

Pros/Cons

	CBTC	Dedicated Loop	Wayside Only
CBTC Software Change	Yes	No	No
Work within Gauge	Maybe	Probably	Maybe
Vehicle units to touch	69	69	0
New wayside sensors for each platform (excluding entrapment)	0	0	8 (front, rear, 2 doors)
New onboard processors	No	Yes	No
Onboard connections to door circuits	Yes	Yes	No
Rough Reliability Estimate*	Good reliability	Good reliability	Not as good

* The reliability of the berthing system for the pilot is not a large consideration, as it is dwarfed by the reliability concerns of the entrapment sensors. ClearSy noted a 0.02% false positive rate per door with entrapment sensing, or 0.48% failure per departure. With the worst-case wayside only berthing system, this raises to 0.64% failure per departure.

Rough Order of Magnitude Cost Estimate

	Unit Cost	CBTC		Dedicated loop		Wayside only	
		Qty.	subtotal	Qty.	subtotal	Qty.	subtotal
Siemens software*	$2,000,000	1	$2,000,000	0	$0	0	$0
- Onboard updates		138	$611,912	138	$845,028	0	$0
- Wayside updates	$1,000	50	$50,000	0	$0	0	$0
Wayside design			$200,000		$300,000		$500,000
Wayside laser	$14,500	0	$0	0	$0	16	$232,000
Wayside loop	$5,000	0	$0	4	$20,000	0	$0
Onboard design			$100,000		$100,000		$0
Onboard devices	$15,000	0	$0	138	$2,070,000	0	$0
Total (1 station)			**$2,961,912**		**$3,335,028**		**$732,000**
Recurring costs	(approx.)						
Per Station			$0		$20,000		$232,000
For 50 stations	(approx.)		**$2,961,912**		**$4,335,028**		**$12,332,000**

1. Yellow numbers are placeholder, pending Siemens input.
2. Only costs impacted by berthing selection are listed

DETAILS

General Concept of a PSD/ASG Station Stop

A Berthing Control System performs the following functions during a normal station stop:

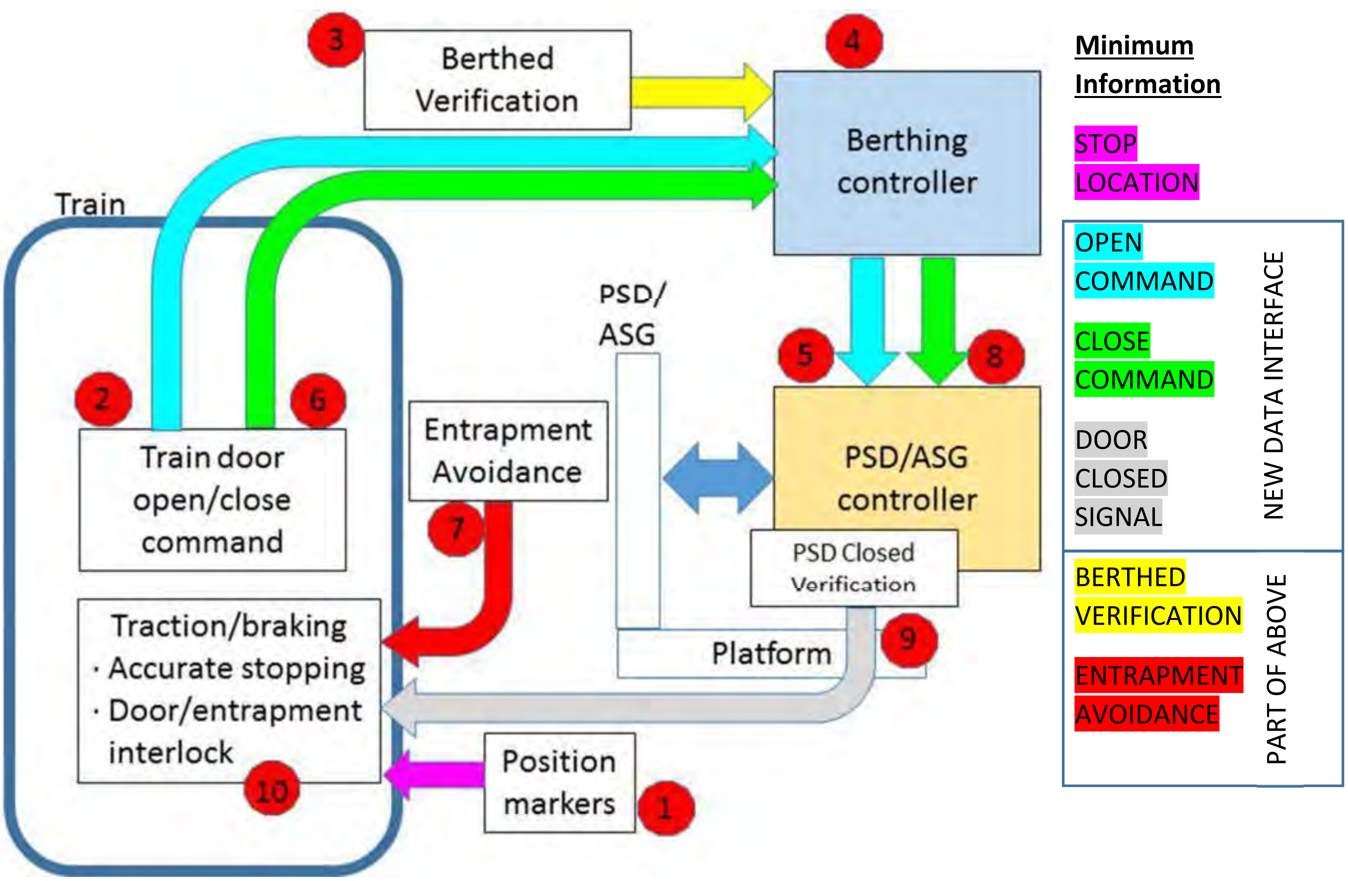
A. Accurate Stopping
   1. Reliably stop train at STOP LOCATION so that the train doors and platform doors are aligned.

B. Open Doors
   2. Transmit OPEN COMMAND from the train to the wayside.
   3. Generate BERTHED VERIFICATION if train is stopped at the correct location and is correct length.
   4. Ensure that OPEN COMMAND and BERTHED VERIFICATION are both present.
   5. Transmit OPEN COMMAND to PSD/ASG controller.

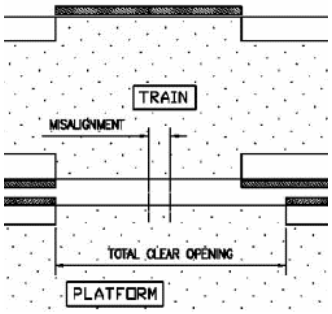
C. Dwell during passenger boarding/alighting

D. Close doors
   6. Transit CLOSE COMMAND from train to wayside.
   8. Transit CLOSE COMMAND to PSG/ASG controller.

E. Safe Movement
   7. Ensure ENTRAPMENT AVOIDANCE by mechanism, geometry, rule, or technology.
   9. Transmit DOOR CLOSED SIGNAL from wayside to train.
   10. Accelerate from station when safe to do so.



Berthing Control Comparison



Stop Location

In order for passengers to enter and exit the train safety, the train doors and platform doors must be aligned. While Paris RATP only requires a 31.5" clear opening, a design for NY should meet the ADA Accessibility Guideline of 36".

Without some form of ATO in place, NYCT will be reliant on the train operator stopping the train within the door tolerance calculated by:

$$misalignment\ tolerance = 0.5 * \ (platform\ opening) + 0.5 * (train\ opening) - 36"$$

The standard methods of improving operator stopping accuracy are (1) stop marker signs visible to the engineer and (2) training. Based on the experience of TfL and Shanghai, this is normally sufficient.

ClearSy has a 'distance totem' which calculates and displays how far the train is from the stop target. It is unclear how beneficial this totem would be in practice, or if it would conflict with signal visibility.

Berthed Verification

Opening of the platform doors is prevented unless the train is stopped within the misalignment tolerance. Opening of some or all platform doors is also prevented if the train is not the full length of the platform. Three methods of verifying the berth location are describe below.

Communication Based Train Control

Utilizing CBTC is feasible if it has accurate location information, accurate train length information, and a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to the schedule/cost impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

ClearSy's COPP system provides a dedicated loop antenna which is placed below the train at the berthing location, with paired antennas installed on the underside of all potential lead vehicles. The loops are sized so that communication is only possible if the train is stopped within tolerance.

On systems with various train lengths the system must also verify train length. This is accomplished with additional loops installed where the rear of the train may berth. Paired antennas must be installed on the underside of all potential trail vehicles.

Magnetic, Laser or Optical Scanners

Where installation of equipment onboard is undesired, berthing location can be verified via remote sensing of the train speed and location. As an example, ClearSy's Coppilot system utilizes wayside sensors to monitor the speed and location of vehicles at the platform.

Where train length may vary, additional sensors are installed where the rear end of the train may berth.

Open Command , Close Command

While not absolutely required, it is suggested that the door open and closed commands be synchronized between the train and platform. The four methods currently in use are described below.

Via Train Control

Utilizing CBTC is feasible if it is interfaced to the doors and has a data path to the wayside. A downside of this method is that it requires additional testing of both safety systems (doors and CBTC). Due to this cost/schedule impact, Paris and Jubliee lines did not connect the ATO system to the PSD/ASG system.

Dedicated Loop

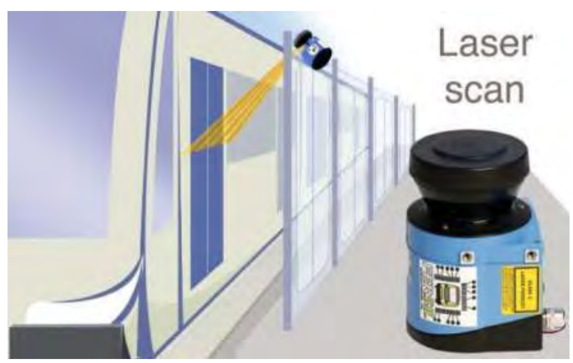
The dedicated loop discussed above (see: Dedicated Loop) may also be used to transmit open and close commands from the train to the wayside.

Radio Frequency

If the CBTC system is interfaced to the platform screen door but does not have the capability of interfacing to the onboard doors, a short range radio may be used to communicate from the train to the wayside. Due to this radio only performing a single function, the dedicated loop discussed above (see: Dedicated Loop), which can also perform berthing verification, appears to always be a better option than a short range radio.

Optically

If installation of equipment onboard is undesired, opening and closing of the train doors can be monitored by ClearSy's Coppilot system optically. Due to platform doors not being commanded to move until after the train doors have been detected as moving, this method may add 1 or 2 seconds to the overall dwell time.



For agencies with operational desires to only open specific doors, additional sensors can be placed to monitor individual doors. However, ClearSy warned that this quickly increases the cost.

Door Closed Signal

All train and platform doors must be closed before the train moves. Monitoring of the train doors is already existing onboard and would remain unchanged. The platform doors are expected to be monitored via a safety circuit that connects to every door in series. If any 'door closed' switch is open, the door is open and the safety circuit will have no power.

Appendix B – Report on Structural Feasibility of Platform Screen Doors for System-Wide Installation

1.0 Executive Summary

The purpose of this document is to provide a general assessment of the structural feasibility of installing Platform Screen Door (PSD) systems throughout the New York City Subway system. This document is intended to address the structural requirements for all PSD systems, common platform construction types in the New York City Subway system, and necessary modifications to the existing structures to facilitate PSD installation. It will provide a broad analysis of PSD installation in the various typical platform configurations, as well as suggested modifications where the existing construction is found to be inadequate.

A visual assessment of photos of all 472 stations in the NYC subway system and a review of record drawings of representative stations along each line indicates that over 90% of stations in the system partially or fully employ one of four common platform edge types, which will be described in further detail in this report. Stations along each line utilize similar edge types, as they were built under the same contracts at the same time. This report will, therefore, describe the structural requirements of PSDs for large portions of the system and provide an order of magnitude of necessary structural modification for large-scale installation of PSDs.

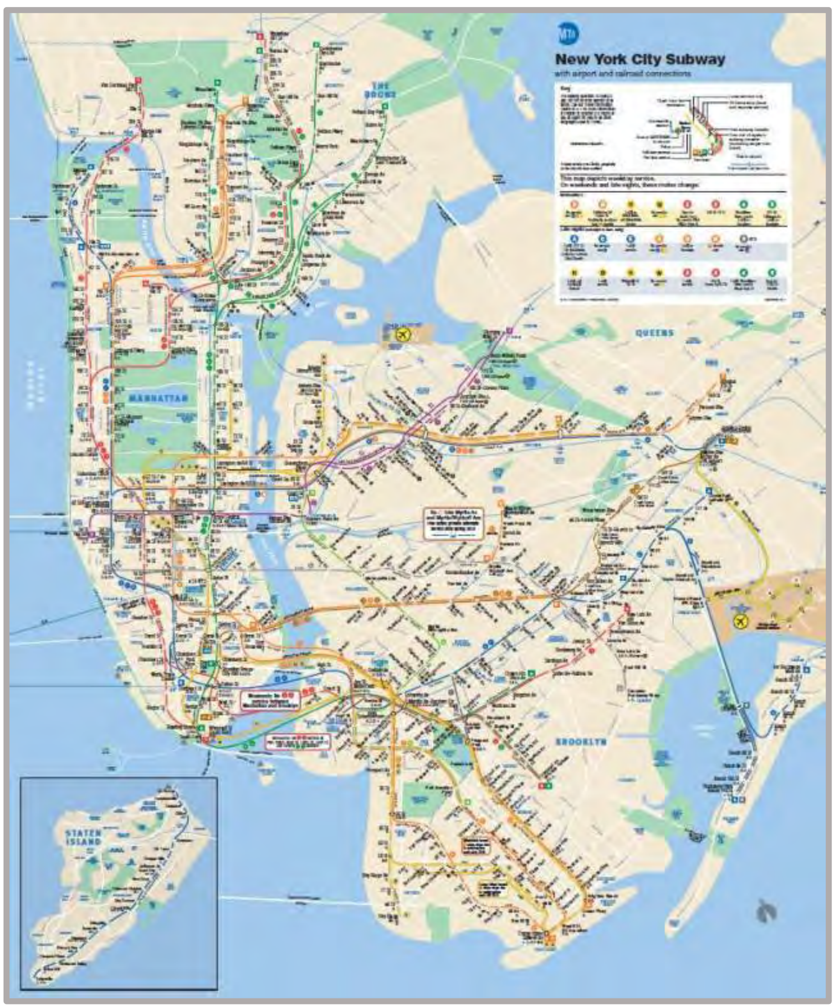

Figure 1-1 Map of the New York City Subway System

If a station is selected for PSD installation, site specific assessment will be required. Many stations will likely require structural repair of damaged or defective concrete prior to installation of a PSD system. A track alignment survey will be required and the platform edge must be reconstructed to meet NYCT-MOW Track Engineering and NYCT-CPM ADA requirements, in addition to other modifications specified herein. Additionally, there may be localized areas where platform construction in a particular station differs from the construction types described herein. This report does not consider the effects of obstructions such as columns, stairs, tapering of platform width and curved track that would not leave sufficient space for PSD installation. These must be considered on a station-by-station basis, as they vary from one station to the next and at different locations within the same station.

2.0 Project Background and Description

At the time of writing this report, STV is in the process of producing a series of feasibility studies for New York City Transit that address the installation of Platform Screen Door systems throughout the city. These studies outline the types of PSD systems in use throughout the world and the compatibility of these systems with existing NYCT rolling stock and signals technology. As these reports are being produced on a line-by-line basis, they will provide a comprehensive analysis of the challenges facing installation of PSDs at specific locations, including architectural, electrical, signals, code compliance, structural, and constructability issues.

Platform Screen Door Systems have been installed in metro systems throughout the world, with some smaller-scale installations in the United States, and are intended to prevent customers from accidentally falling, jumping, being pushed, or otherwise accessing the tracks illegally. In addition, PSDs can prevent debris and trash from accumulating on the tracks, reducing the risks of track fires. PSD systems commonly take one of two forms—a full-height barrier that extends from floor to ceiling (or fully encloses the track) or a partial-height barrier that extends some distance above the platform slab (typically at least 4'-0"). These barriers typically consist of a series of sliding glass doors, fixed glass panels and metal mullions that sit on the platform edge, with the platform doors aligning with those on the train cars.

Figure 2-1 Partial-Height Platform Screen Door System by Gilgen Door Systems

As a result of the feasibility studies produced by STV, it has been determined that partial-height Platform Screen Doors (also known as Automatic Platform Gates) are the most practical system for installation in the New York City Subway. The partial-height PSDs under consideration consist of a cantilevered glass and metal door system, to a height of approximately 4'-6" above the platform slab. This system provides the benefit of preventing customers from falling, jumping, or being pushed onto the track without impeding air flow within stations. Additionally, the half-height barriers allow conductors to see the train doors while they open and close, as they do currently.

In addition to the feasibility studies currently being produced, STV is in the process of producing preliminary construction documents for the design-build of half-height PSDs at the Third Avenue station on the BMT Canarsie Line ("L" Train) in Manhattan. This station will serve as the pilot program for PSD installation in the NYC Subway.

This report focuses primarily on the installation of half-height cantilevered PSDs, similar to those being proposed at Third Avenue Station. Full-height PSD systems are also discussed, although they are likely precluded in many stations due to overhead obstructions, lack of compatibility with current NYCT operating procedures, and the need for station ventilation. A full-height system would require less strength from the platform edge, but would require an assessment of the roof, canopy, or ceiling structure above. In addition, a full-height system would require an assessment of obstructions that would preclude attachment to the structure above at each station, as these conditions vary greatly, even within the same station. Full-height PSD systems are not feasible at elevated stations outside the canopy area, as they do not otherwise have a structure to support the top of the barriers.

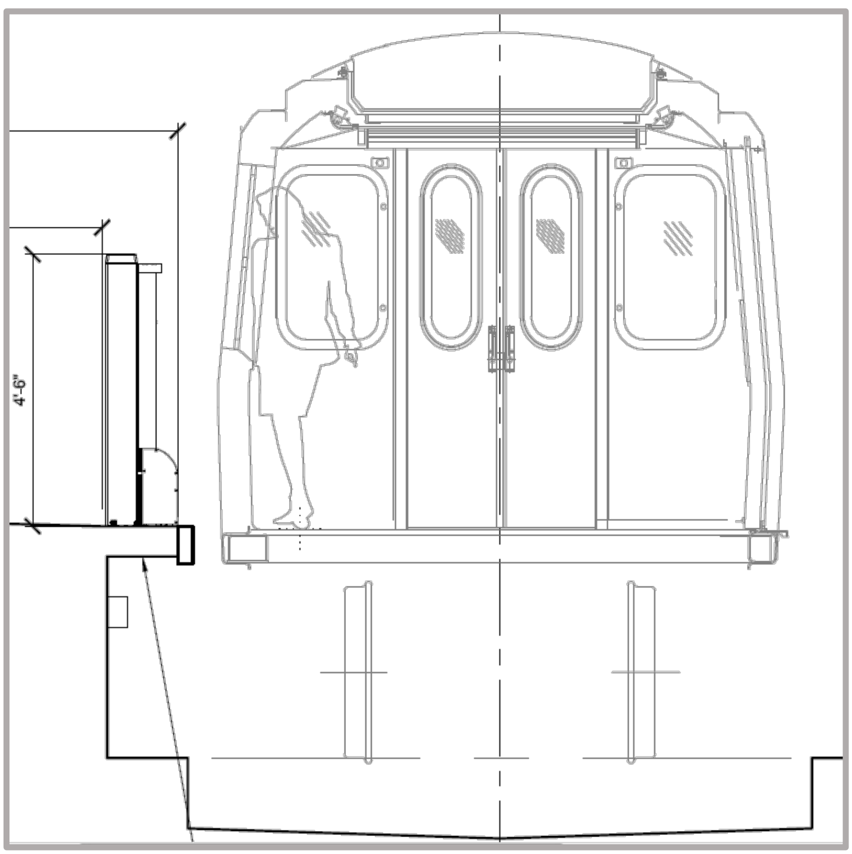

Figure 2-2 Section through Platform Screen Door System Proposed at Third Avenue Station

3.0 Structural Design Criteria

The structural design of the PSD system is governed by several loads: the "wind" load of train movement through the station, known as the piston effect, the force of a crowd being pushed against the barrier, and fatigue loading on components due to the repetitive movement of trains into and out of the station. Due to the unique nature of this project, there is no guidance on the magnitude of the design loads in current building codes or New York City Transit Design Guidelines. As a result, design loads have been determined based on manufacturers' requirements for similar installations in other metro systems around the world, such as London, Paris, and Hong Kong.

The self-weight of the PSD system will be dependent upon the actual system implemented, but for the purposes of this report, it is assumed to be about 150 lbs/ft. of barrier length. That accounts for approximately 1" thick glass, as well as intermediate mullions and mechanical equipment. This will likely be similar for both full-height and half-height barriers, as full-height barriers require more glass, but less intermediate support since they are not cantilevered. The weight of the PSD system will likely not control the design of the platform below, as it is typically wide enough such that the center of mass of the wall is located closer to the support than the edge of the cantilever. It is, nonetheless, an important consideration and the designer of record for any PSD installation project must verify the actual weight of any PSD system to be installed with its manufacturer.

The largest force applied to the PSDs is the crowd thrust force, which was considered to be 210 lbs/ft., applied 4 feet above the platform slab along the length of the doors. The only analogous load in current building codes (including the 2015 International Building Code, adopted by New York State) is that used for guard rails, defined as a concentrated load of 200 lbs or a distributed load of 50 lbs/ft. along the length of the rail. The design load far exceeds the code requirement for guard rails and is equivalent to the load used in similar metro systems in other cities.

The piston effect produces a load that is more challenging to quantify, as it is likely highly variable depending on station geometry and train velocity, with below grade stations experiencing much higher forces than above grade stations (though above grade stations will experience wind loading and piston effect simultaneously). The design load used for Third Avenue Station (and for the analyses in this report) is 36 $lbs/ft.^2$ (psf), also based on the load criteria for other cities. It is worth noting that this is in excess of typical exterior wind loads used for building design in New York, roughly equivalent to a 110 mph wind. If a large-scale installation of PSD systems is undertaken, site specific analyses of piston effect pressures in stations should be performed to create more refined design criteria. Other loading, such as snow, ice, seismic loading and thermal effects shall be considered for PSDs at all above grade stations.

Due to the repetitive nature of the loads on PSDs, fatigue is also a consideration. The design criteria for this project, based on similar installations in other cities, is to design the PSD system and its components for a fatigue load of ±11 psf, with an expected frequency of 185,000 cycles/year. Steel components of the door system and anchorage to the slab can be analyzed for fatigue using procedures defined by the American Institute of Steel Construction (AISC). If post-installed anchors are utilized to connect the PSD to the slab, an independent laboratory test for fatigue should be undertaken, as fatigue and dynamic load testing data are not readily available. The effects of fatigue on the concrete platform slab are less clear, as concrete fatigue is not an issue addressed by American building codes. The American Association of State Highway and Transportation Officials (AASHTO) Bridge Design Specifications provides some guidance on fatigue effects in concrete, which can be adapted to ensure that the platform edge is sufficiently reinforced to support cyclical loading. This will be discussed in further detail in **Section 5.0**.

4.0 Description of Existing Platform Types

Though the New York City Subway system is extraordinarily expansive, with 472 stations, a surprisingly small number of designs were employed for platform slabs. A visual assessment of photos of all stations and an analysis of record drawings for select stations along each line to confirm visual observations indicates that over 90% of stations in the system primarily employ one of four basic platform types. Individual platforms may differ in localized areas, as they have been expanded and modified throughout the 114 year history of the subway system, but almost all platforms partially or fully utilize the systems described below.

4.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Prior to about 1935, below grade (and some open cut) stations constructed for the IRT, BMT and IND subways utilized cast-in-place concrete platform slabs with inverted steel WTs embedded in the concrete at a spacing of 20 inches on center. Rather than being a true concrete cantilever, the steel cantilevers approximately 1'-2" over the supporting wall below and a thin concrete slab spans between the two adjacent WTs. A continuous steel angle runs along the edge of the platform. The concrete slab contains little or no reinforcing. A topping slab provides additional thickness, as well as a slope toward the tracks. See **Figure 4-1** below for additional information.

This slab type is inadequate to carry the weight of the new PSD system and its design loads, whether half-height or full-height barriers are used. Due to the lack of reinforcing in the slab edge, it is recommended that slabs constructed in this manner be rebuilt and tied into the existing structure through the use of dowels and epoxy bonding agents. This will be further discussed in **Section 5.0**. Typically these platform slabs are supported by continuous concrete walls, which will experience minimal additional loading due to the PSDs.

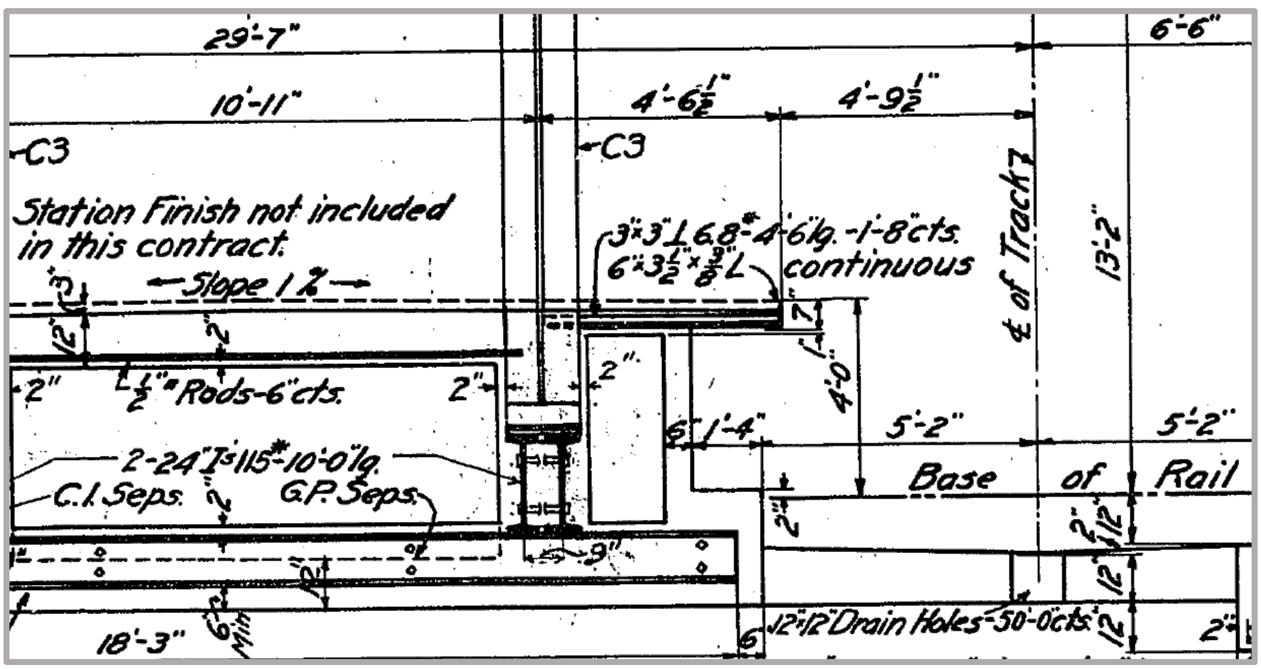

Figure 4-1 Partial Section of Platform at President Street Station (IRT Nostrand Avenue Line, Brooklyn; "2" & "5" Trains) showing Inverted WT Construction. Station was opened in 1920.

4.2 Cast-In-Place Concrete Slab with Steel Rebar

In newer below-grade stations, particularly those built after 1935, and some open-cut or at-grade stations, the platforms are approximately 6" thick cast-in-place concrete slabs with steel rebar, similar to what one might expect if the station were constructed today. The cantilever is typically about 1'-2" long, from the face of the supporting wall. In some cases, a continuous steel angle may be utilized at the edge of the slab, behind the rubbing board. If present, this angle is typically cast into the slab with steel straps. See **Figure 4-2** for one example of this type of platform construction.

The rebar in this slab, as well as the cantilever length, varies from station to station and within many stations. As a result, its ability to support the loads produced by the PSD system will vary and a site specific analysis must be performed. Some stations, particularly newer stations, will be able to support the PSDs without modifying the platform slab, but some older or deteriorated slabs may require a partial or full rebuild. These slabs are more likely able to support full-height barriers than half-height barriers, as the full-height barriers produce only a shear force at the base, whereas half-height barriers are cantilevered and produce a rotation at the edge of the cantilever. In order to prevent base rotation, full-height barriers must also have top supports connected to the roof structure of the station, which may be difficult if there are overhead utilities, signs or other obstructions. The roof structure must also be checked both locally and globally for the effects of PSD loading, which must be done on a station-by-station basis.

Slab repair and modification work will be discussed in further detail in **Section 5.0**. Additionally, the effects of loading on the support structure below shall be considered. In many cases, the platforms are supported by continuous concrete walls, which can support the PSD system and will experience minimal additional loading. In other cases, or where the walls are found to be deteriorated or deficient, the supporting structure may require reinforcement or reconstruction in order to support the PSD weight and its design loads.

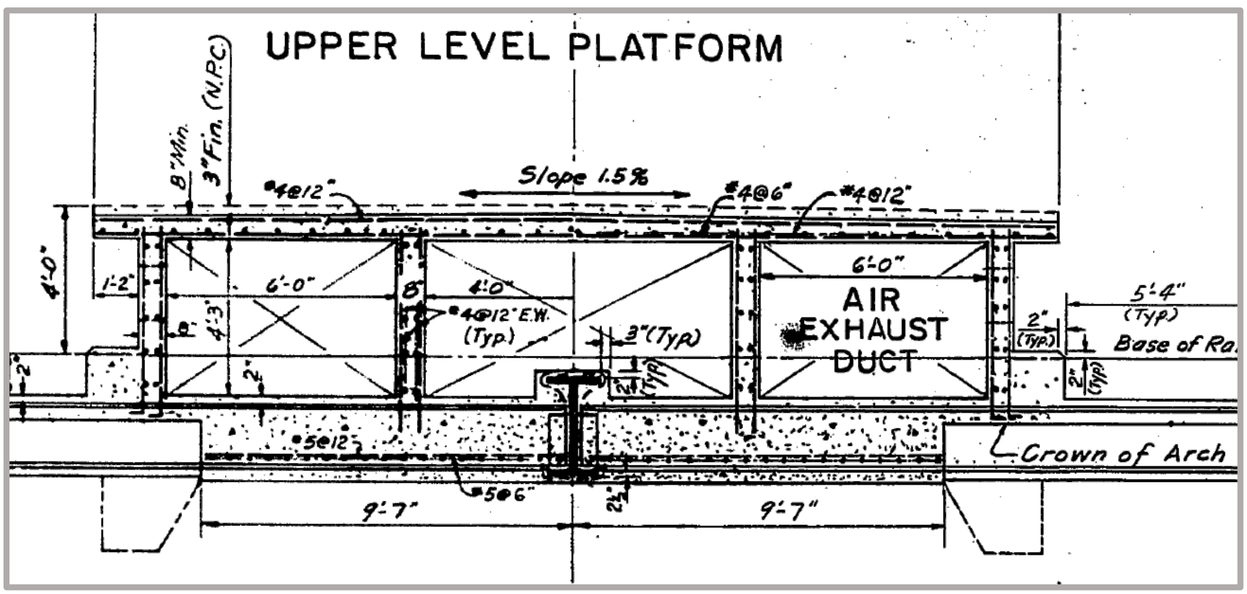

Figure 4-2 Section through Platform at Jamaica Center-Parsons/Archer Station (IND/BMT Archer Avenue Lines, Queens; "E", "J", and "Z" trains) showing Cast-in-Place Concrete Cantilever Construction. (Station was opened in 1988.

4.3 Precast Concrete Platform (Elevated Stations)

Starting around 1960, the wood platforms at elevated stations were replaced with predominantly precast concrete slabs. About 70% of elevated platform structures consist, at least partially, of precast concrete slabs. These are typically double-tee beams supported by the steel track structure below. The overall width of the beams varies, but the stems are typically 3'-0" apart. Some of the precast beams are prestressed and contain prestressing tendons in addition to mild reinforcing steel. The stems of the tees are connected to short pipes, which are welded to the steel platform girders below. Between stems, the slab is fairly thin, about 3 ½" thick, and reinforced with welded wire fabric. See **Figure 4-3** for a typical detail of a prestressed platform slab.

While the overall design of precast concrete platforms varies from line to line (typically, multiple stations were completed under one contract with the same details), the precast concrete platforms generally cannot support the design loads of a PSD system. The thin slab is not capable of withstanding the rotation created by a cantilever PSD system, as it will experience torsional forces between stems. As a result, any precast beam will require some degree of reinforcement, largely driven by the spacing of the stems. Additionally, the steel station structure and pipe supports for the precast beams must be analyzed on a site-specific basis for added weight and additional imposed loading. The reinforcing of precast concrete platforms is discussed in further detail in **Section 5.0**.

The PSD system may also present logistical challenges in a precast structure, as the base connections and necessary penetrations for conduits may interfere with existing reinforcing or prestressing steel. A cast-in-place concrete slab allows for the use of post-installed adhesive anchors at base connections or for the slab to be rebuilt with base connections cast into the slab. This is not possible with a precast concrete slab, as the use of post-installed anchors would be precluded by the thin slab. The only viable option for a base connection is the use of thru-bolts, which may be challenging, as the stems and existing reinforcement must be avoided. Installation of PSDs at elevated stations with precast concrete platforms will present substantial challenges, possibly necessitating major modifications to the existing structures.

Full-height PSD systems are likely precluded from use at nearly all elevated stations, as they do not have canopy structures running the full length of each platform to support the top of the barrier. If a full-height barrier is to be used, it would have to be cantilevered in a similar way to the half-height barriers and would produce a greater base reaction at the platform slab edge.

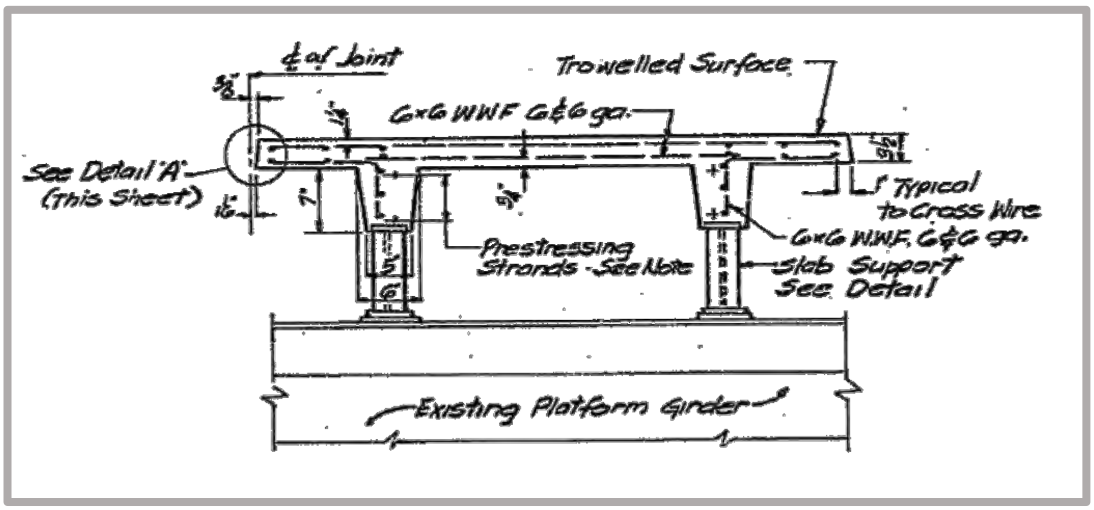

Figure 4-3 Section through Typical Prestressed Concrete Platform Slab (IRT Pelham Bay Parkway Line)

4.4 Cast-in-Place Concrete Slabs (Elevated Stations)

While the majority of elevated stations have precast concrete platforms, some stations and portions of nearly all stations have cast-in-place concrete platforms. Typically these are found in stations where the platform is located above the mezzanine, or near the head house if the station does not have a mezzanine. In nearly all cases, these cast-in-place concrete platforms are supported by steel platform girders. Like the below grade cast-in-place platform slabs, these platforms are highly variable depending on station geometry, configuration of the steel framing below, and time at which they were constructed. Some platforms are more heavily reinforced than others and the cantilever length (beyond the girders below) varies by location. See **Figure *4-4*** Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)**Figure *4-4*** for one example of a cast-in-place concrete slab at an elevated station.

At these stations, or sections of stations, the concrete slab will have to be analyzed on a site-specific basis to determine its ability to carry additional load at the platform edge. Modification or reconstruction of a portion or all of the platform may be required in order to support the PSD system at some locations, while others will require little to no modification. Elevated stations are much more variable than below-grade stations, as they were built at different times, under different contracts, and for different rail companies. As a result, there will not be a "one size fits all" approach for modifying these slabs. Some potential modification options will be discussed in further detail in **Section 5.0**. Additionally, the platform structure below will have to be analyzed for the impact of additional loading due to torsion at the base of the PSD and added weight of the system. The steel structure may require reinforcement if it is found to be insufficient to support the PSD system.

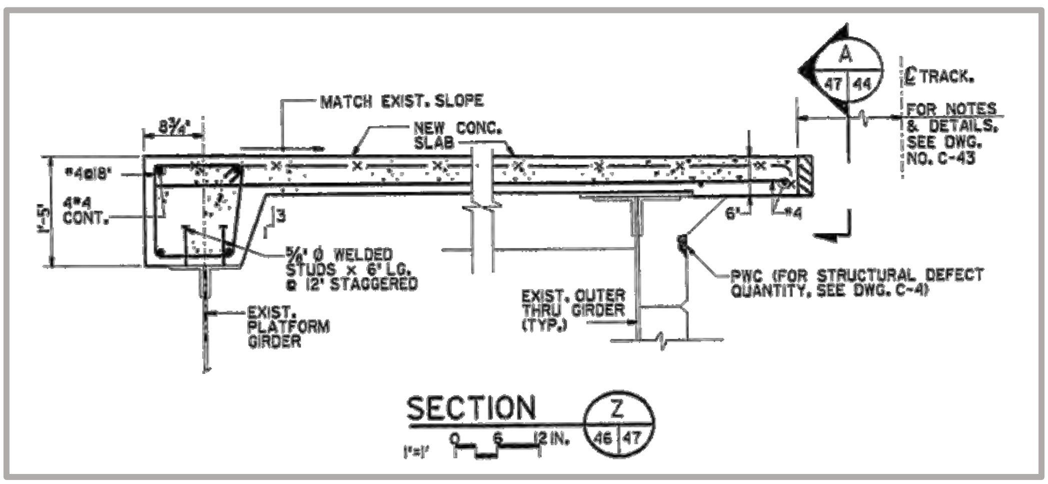

Figure 4-4 Typical Cast-in-Place Concrete Slab Detail for Rehabilitation of Stations on the BMT Broadway-Jamaica Line ("J" & "Z" Trains)

4.5 Other Known Platform Types

While the four platform types described in this section cover about 90% of stations in the system, some other platform types do exist and will have to be dealt with on a case-by-case basis if PSDs are installed at those locations. Some elevated stations utilize precast concrete planks other than double-tees, which can be evaluated at each site independently. If they are found to be insufficient, the platform would likely have to rebuilt to support the PSD system. Additionally, one elevated platform (Court Square on the IRT Flushing Line) utilizes fiberglass (GFRP) platforms. This platform could not be reinforced traditionally and would have to be rebuilt if the GFRP is unable to support the PSD design loads.

Some stations, particularly in Brooklyn and Queens, employ open-cut construction, which is similar to, yet distinct from below-grade stations. These stations typically utilize cast-in-place concrete platform slabs, but they are not supported by a continuous concrete wall like nearly all of the below-grade stations. Additionally, some sections of these stations have little or no cantilever toward the tracks. The concrete at many of these stations is significantly deteriorated (likely due to exposure to rain, snow, and de-icing salt over the last 100 years or more) and extensive reconstruction of the platforms would likely be necessary in order to install PSDs at these locations. Where the concrete is observed to be in good condition, site-specific assessments are needed to determine the adequacy of the existing structure to support the PSDs.

One distinct section of track is the IND Rockaway Line in Queens. This section of track was originally operated by Long Island Railroad and is unlike any other portion of the NYC Subway system. The tracks are elevated on a steel viaduct encased in concrete, giving the appearance of a reinforced concrete viaduct. The platform slabs are cast-in-place concrete and have longer cantilevers than elsewhere in the system (up to 2'-9"), but were rebuilt in 2014 and can support the loads due to a PSD system without major reconstruction. Some modification would be required to accommodate electrical systems and conduits for the PSD system. A more detailed analysis is required to determine if the supporting structure can support the added loads from the PSD system, considering the effects of added weight, seismic loads, and wind loads, as well as any locally critical areas or areas in need of repair. This type of construction affects (8) stations. A typical detail for platform construction along the IND Rockaway Line is shown in **Figure 4-5**.

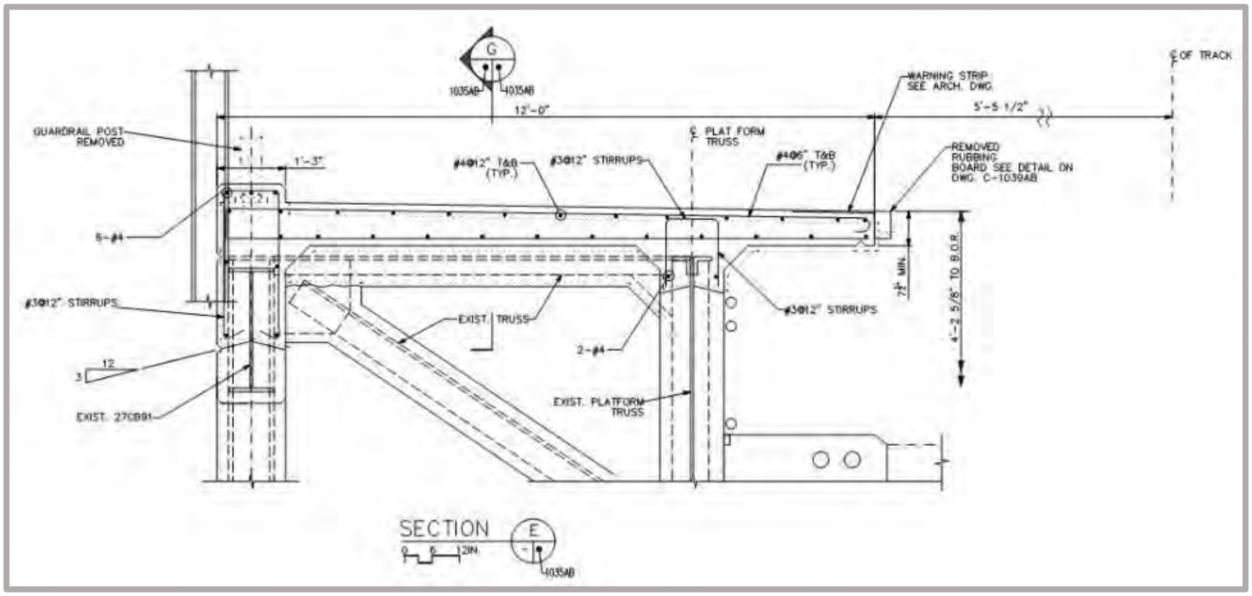

Figure 4-5 Section through Typical Platform Construction along the IND Rockaway Line in Queens

5.0 Required Platform Slab Modifications

5.1 Cast-In-Place Concrete Slab with Embedded Steel WTs

Cast-in-place platform slabs supported by steel WTs are insufficient to support the PSD system, as the structural slab is very thin and contains little or no reinforcement. As a result, it is recommended that the steel WTs be removed and the slab be rebuilt to a thicker dimension with sufficient rebar to support the PSDs. The existing condition consists of an approximately 3” thick structural slab with an approximately 3” thick topping slab. If the topping slab is fully removed, a 6” thick structural slab can be constructed. This provides sufficient reinforcement to support the PSD system and allows for cast-in base connections or conduits as needed. The exact reinforcement will be dependent upon the cantilever length, but a 6” thick slab will be sufficient for a cantilever length of up to approximately 3’-0”, greater than what is typically found in below-grade stations. Removal of the existing concrete slab over a duct bank (a condition which exists in many below-grade stations), carries a risk of damaging the ducts. As a result, non-destructive testing should be utilized to identify the depth to the ducts prior to demolition. It may be necessary to rebuild the top layer of the duct bank in order to accommodate the new slab, which requires temporarily relocating these cables.

A new topping slab can be provided in addition to the 6” structural slab, which will provide additional surface for durability, allow for equipment to be flush with the concrete surface, and raise the platform to ADA height. This work may be performed in conjunction with an adjustment in vertical track alignment in order to achieve the desired platform height. This is similar to the proposed construction at the Third Avenue station on the BMT Canarsie Line, shown in **Figure 5-1** and **Figure 5-2**. If a topping slab does not currently exist, other options, such as lowering the bottom of the slab, may be explored to achieve the required 6” minimum thickness. Where it is not possible to lower the bottom of the slab due to the presence of a duct bank, it may also be possible to raise the track alignment to achieve the desired platform slab thickness and height.

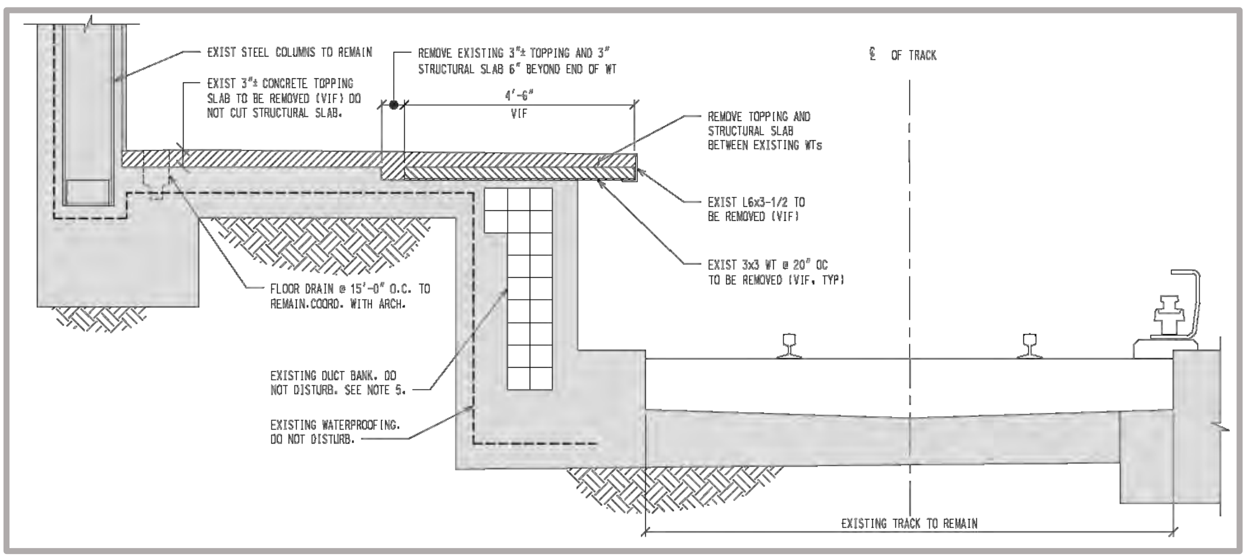

Figure 5-1 Proposed Demolition of Concrete Slab with Steel WTs at Third Avenue Station

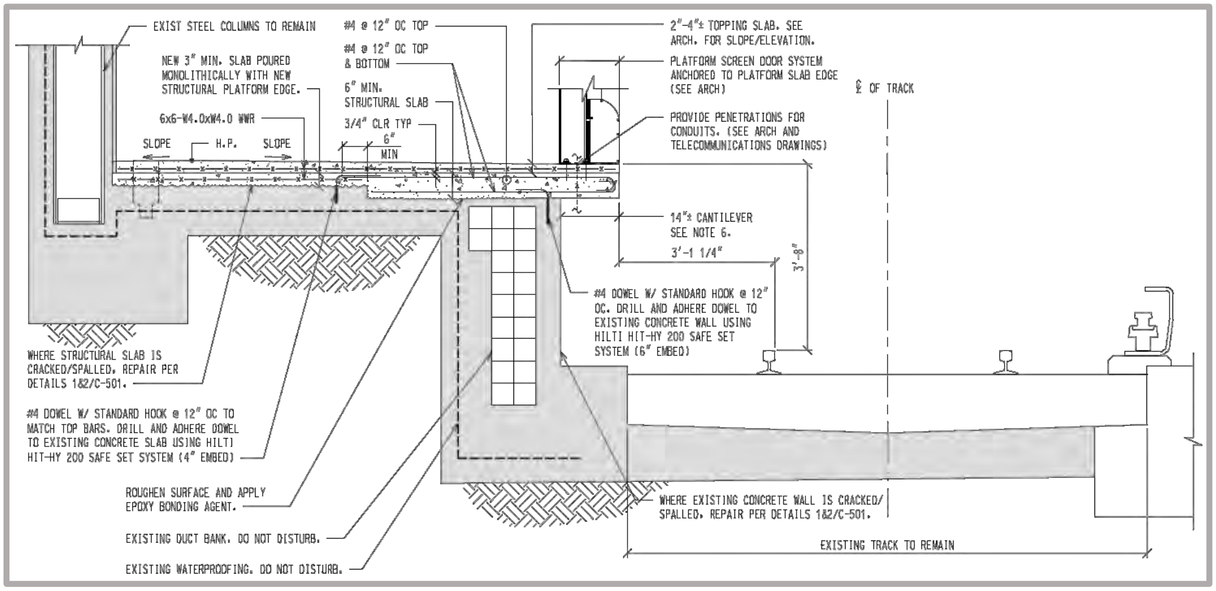

Figure 5-2 Proposed Reconstruction of Cast-in-Place Concrete Platform with PSDs at Third Avenue Station

5.2 Cast-In-Place Concrete Slab with Steel Rebar

Reinforced cast-in-place concrete platform slabs may have sufficient capacity to support a PSD system and a site-specific analysis of the slab is necessary to make this determination. If sufficient capacity exists, the PSD system can be anchored to the concrete slab using post-installed anchors. The PSD system may require core-drilled holes for conduits and cables to pass through the slab, which must be coordinated with any existing reinforcement. In addition, any deteriorated concrete must be repaired prior to installation of a PSD system.

If the platform slab is found to be insufficient to support the PSD system, the slab can be reconstructed in a manner similar to the cast-in-place slab with steel WTs. The cantilever and a portion of the backspan can be removed while preserving concrete and rebar in the remaining portion. New rebar can be doweled into the remaining portion of the slab and a new cantilever can be poured with any necessary base anchors or conduits cast in. Alternatively, or if the slab is severely deteriorated or damaged, the entire platform slab can be rebuilt with sufficient capacity to support the PSD system. A topping slab can be provided for added durability and to allow for flush-mounted equipment in the concrete.

5.3 Precast Concrete Platform (Elevated Stations)

The precast double-tee beams used at most elevated stations have very thin slabs (approximately 3 ½" thick) and are unable to support the added load due to a PSD system. Reinforcing these platforms is somewhat more complex than at below grade stations, as the precast concrete cannot be cut and partially reconstructed. In order to reinforce these members, new concrete must be added between the stems of the double-tee to stiffen the slab. A layer of reinforced concrete approximately 4" thick would be required to reinforce the slab, with dowels drilled into the stems of the double-tee.

Construction of this reinforcement would be challenging, as it is between the steel platform and the underside of the platform. In some stations, this may be possible through the use of stay-in-place formwork, but in other locations there may not be enough space to construct the reinforcement. Additionally, the use of stay-in-place forms is not desirable visually, as they will ultimately rust, giving the appearance of structural damage in publically visible areas. In order for any new reinforcement to be added, dowels must be provided at the stems of the precast tees, which carries a considerable risk of damaging the tendons. Non-destructive testing measures and probes must be utilized to lower this risk, which complicates the work and increases cost. The proposed reinforcing is shown in **Figure 5-3**.

The stations would require additional modifications for the installations of cables and conduits below the slab edge, as the platform does not cantilever in a similar way to the underground stations' cast-in-place platforms. Running cables and conduits parallel to the track would be complex, as they cannot simply pass through the stems of the double-tee beams. Penetrations through the stems and their reinforcement would significantly reduce the capacity of the double-tees and is not acceptable. Conduits would have to run below the precast-concrete, which may not be compatible with the PSD system. In addition, there may be obstructions in the steel framing below. Additional slab penetrations are necessary to bring electrical and signals wiring to the doors themselves, but these must occur between stems and the stems may be located directly below the doors. In short, modifying the precast concrete platforms to support the PSD system and its associated equipment is structurally possible, but may not be constructible given the complexity of these stations. If that is the case, the only option would be total reconstruction of the platform using either cast-in-place concrete or precast concrete specifically designed for PSD systems.

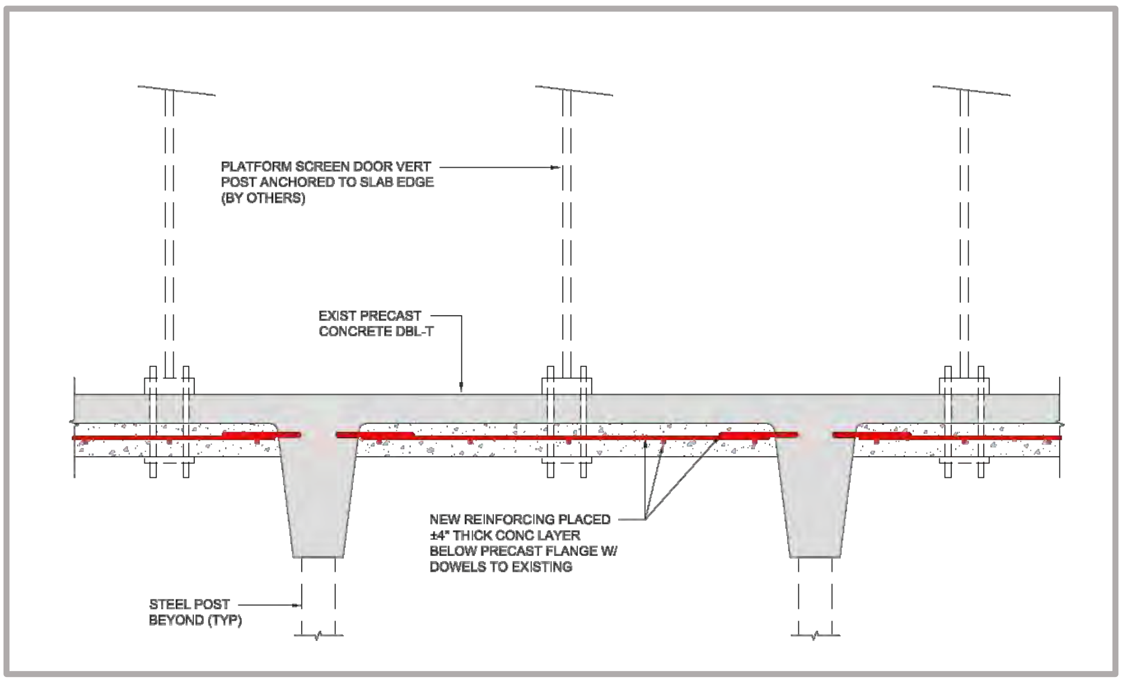

Figure 5-3 Section through Precast Double-Tee Platform Slab showing Possible Reinforcing (View from Track)

As nearly all elevated stations are supported by steel framing, the strength of the steel should be verified on a station-by-station basis to determine that it can support additional superimposed loads due to the PSD system.

Where cast-in-place concrete slabs exist above mezzanines, special consideration must be given to any waterproofing present. If the slab is partially rebuilt or if openings are drilled or cut for conduits and anchor bolts, any waterproofing membrane between the platform and mezzanine must be maintained.

5.4 Cast-in-Place Concrete Slabs (Elevated Stations)

As with below-grade stations, elevated stations with cast-in-place concrete slabs may have sufficient capacity to support the PSD system, depending on slab thickness and reinforcement, and must be analyzed on a site-by-site basis. Newer stations (or recently rehabilitated stations) are more likely to be able to support the design loads and are least likely to be deteriorated or require repair. Modifying cast-in-place platforms is less complicated than modifying precast platforms, as a portion of the slab can be removed and replaced with more heavily reinforced concrete, similar to what is proposed for below grade stations. This allows for better coordination with any potential penetrations through the slab, as well as anchor bolts for the PSDs.

If the slab is found to be severely damaged or deteriorated, the entire platform may be reconstructed. In addition, a topping slab can be provided, similar to below-grade stations, though the added weight of a topping slab may not be acceptable at elevated stations. The steel framing of elevated stations should also be verified to determine if it is capable of supporting the added weight and applied loads due to the PSD system and added concrete. Reinforcing (involving plates field-bolted to the framing) may be necessary in some locations. Deteriorated or damaged platform framing should be replaced or repaired.

5.5 Other Known Platform Types

While approximately 90% of platforms in the system can be considered one of the four types previously described, some outliers do exist. Precast concrete planks are utilized in some stations, where they span between steel girders. If these planks are found to be insufficient to support PSD installation, it is possible to reinforce them in a similar fashion to the double-tees. It may also be possible to reinforce the concrete with FRP if the bottom face requires additional tensile capacity. Precast planks present a similar challenge to the double-tees, as they require penetrations to be core-drilled while avoiding existing reinforcing or pre-stressing tendons.

Stations along the Rockaway Line and open-cut stations utilize cast-in-place concrete slabs and can be modified using the techniques described in Sections 5.2 and 5.4. Partial or full removal and replacement of the platform would provide a suitable structure to support the PSDs and its associated equipment. This also allows for necessary embedded equipment or penetrations. Many open-cut stations are deteriorated due to exposure to the elements and would likely require repair of concrete supporting the platform.

6.0 Other Structural Considerations

6.1 Global Stability Concerns

While this report has generally focused on localized loading due to the installation of PSD systems, the global stability of each station structure must also be taken into consideration for elevated stations. As nearly all elevated station structures are partially or fully open structures, the PSDs are subject to substantial wind loads. As a result, the overall projected wind area of each station may increase. This is a global analysis that must be done on a station-by-station basis in order to determine that the beams supporting the platforms, as well as the columns and frames below the station, are adequate to resist the larger wind loading. If they are found to be insufficient, reinforcement may be necessary through the use of field-bolted plates.

Similarly, the installation of PSD systems will add to the seismic weight of the elevated stations, increasing the seismic loads experienced by each station. While this must be taken into consideration on a case-by-case basis, it is not likely that the effective seismic weight of the structure will increase by greater than 10% due to the additional PSD self-weight. If it is in fact less than 10%, a full seismic analysis is not required by the 2015 International Existing Building Code (as adopted by the State of New York), as lateral loads have not substantially increased due to the alteration.

6.2 Deflection and Serviceability

Deflection limits for the PSD system must take into consideration any limitations of the PSD system itself (either material or mechanical system tolerances) as well as criteria set by the IBC, whichever is more stringent. The IBC sets a deflection limit for exterior and interior partitions with flexible finishes to L/120, which should not be exceeded. It will ultimately be the responsibility of the PSD manufacturer to design the system such that it can withstand the design loads without exceeding reasonable deflection limits, taking into consideration any local track curvature and train car sway as potential collision obstacles.

Whether located in elevated or below-grade stations, the PSD system will be susceptible to vibrations due to wind load, train movements, mechanical systems associated with the PSD, and their combined effects. The PSD system and its components must be designed to withstand and accommodate these effects without affecting system performance.

6.3 Expansion Joints

PSD systems must be able to accommodate longitudinal movement due to thermal expansion and contraction. Joints between mullions and walls/doors shall be designed to move such that there are not rigid points at the mullions which could result in cracking due to expansion and contraction. Additionally, elevated station structures have existing building expansion joints along their length. The expansion joints within the PSD system must be designed to accommodate multi-directional movement at these locations. It will be the responsibility of the designer of record to coordinate the location and behavior of expansion joints at each station with the PSD system manufacturer.

6.4 Equipment Rooms

In order to support the installation of PSD systems, communications equipment rooms and storage space for PSD system parts must be provided at each station. The exact location of these rooms must be coordinated with all trades, particularly communications in order to ensure proper functionality of the PSD system. They may be located at the platform, at the mezzanine, or in other back-of-house spaces, but the capacity of the floor slab and substructure must be verified to ensure that it can support the additional load. This is likely not a problem at below-grade stations, where platforms and mezzanines have been designed for a live load of 150 psf, but elevated structures are designed only for a live load of 100 psf and will require reinforcement or modification. In addition, high-load zones of racks, batteries, material stacking, etc., must be reviewed for other specific structural effects.

6.5 Existing Utilities

Below grade stations typically have duct banks, cables, conduits, and other utilities located below the platform edge. Installation of the PSD system, modifications to the platform slab, and penetrations for PSD conduits will require altering or rerouting of these utilities. In some cases, this may require partial removal and relocation of the utilities and duct banks to accommodate the new PSD system and its associated conduits. If a full-height PSD system is provided, similar consideration must be given to lighting and overhead utilities. Additionally, in some stations, signal heads may be mounted near platform edges, which will require relocation to accommodate the PSD system and its associated utilities.

6.6 Constructability

Construction phasing and sequencing should consider temporary conditions that may result in a weakened structural element. As an example, at below grade stations, it is not uncommon for the groundwater table to be higher than the platform. If the slab is being partially demolished and reinforced, the temporary condition between demolition and the new slab being poured will be vulnerable to hydrostatic uplift pressure. Care should be taken to avoid removing the entire slab at once, as this could allow cracking and infiltration of groundwater. This, and other constructability issues, should be addressed on a case-by-case basis, as there may be multiple options to mitigate this effect.

6.7 Final Design

While this report attempts to provide a broad overview and summary of the structural implications of installing a PSD system at various station types throughout the NYC Subway System, the final design of the system must still be assessed on a case-by-case basis at each of the 472 unique stations. The designer of record for each station ultimately must verify design loading and determine the necessary modifications for that particular station. Design loads considered in this report are based on similar applications in other cities and should be independently verified prior to final design.

7.0 Summary of Recommendations

Due to the age and complexity of the stations in the New York City Subway system, nearly all platforms will require some form of structural modification or reinforcement to support the installation of a Platform Screen Door system and its associated equipment. Most platforms lack the strength to support PSDs at the edge of a cantilevered slab edge and many are deteriorated due to age and require some form of repair. As a result, more than half of below-grade stations (at a minimum) and nearly all above-ground stations require substantial reinforcement or modification of the platform slabs to support PSD installation.

Cast-in-place concrete platforms, both above and below-grade, can be partially reconstructed to provide the additional strength needed at the slab edge, as well as any necessary penetrations for wires and conduits. While this work is extensive, it will be significantly less disruptive than reconstructing the entire platform.

Modification of precast concrete platforms, common in elevated portions of the system, will be significantly more challenging than modifying cast-in-place concrete. Precast concrete cannot easily be cut to allow weak portions to be rebuilt and would require complex reinforcement and field-drilled holes for anchors and conduits. This work may be substantially disruptive to the existing structure that it may require full reconstruction of the platforms and replacement with either cast-in-place concrete or precast concrete specifically designed for PSD systems. If a large-scale installation of PSDs is planned for the New York City Subway system, perhaps the most practical solution for elevated stations is a replacement of nearly all platforms, as was undertaken in the 1960s to install the precast concrete.

In summary, Platform Screen Door systems provide unique structural demands that were not anticipated in the original design of the New York City subway system. Consequently, it is more likely to encounter platforms that cannot support these systems than those that do. Modifying these platforms to support such a system is possible, but would necessitate a large-scale overhaul of each platform, similar to what is proposed for the Third Avenue station.

End of Report

Appendix C – Emergency Egress Width Analysis

Emergency Egress Width Analysis

As part of the System-wide PSD Feasibility Study, the purpose of this memorandum is to establish a minimum platform width required for side and center platforms to be considered feasible for the design and installation of PSDs. It is not based on an actual designed installation of PSDs at a particular station but is intended to establish reasonable minimum widths to use as criteria for the study.

Assumptions:

1. NFPA130 timed egress analysis will be the final determinate regarding code compliance if and when a design is developed for the installation of PSDs at a particular station. This document is not a substitute for such analysis and it may be that particular configurations for a given station may prove that even these minimums are not enough to achieve code compliance for egress.

2. This document assumes that the minimum width of egress along the platform is determined by the size of the emergency egress doors (EEDs) exiting from the train onto the platform. In order to comply with the door leaf encroachment requirements of NYS BC 2015 (Section 1005.7.1) and NFPA130 referencing NFPA 101 2018 (Section 7.2.1.4.3.1) the width of the egress path must be at least twice the width of the largest EED.

3. In order balance the egress width from the train with the constraints of existing narrow platforms we have chosen double egress doors with two 22 inch leaves as the optimal width for each EED. This provides a reasonable egress door width from the train when improperly berthed while also providing a good fit between the motorized sliding doors (MSDs).

The worst case scenario governing the platform width is the circumstance of two simultaneous events: The improper berthing of a train and a fire or other emergency requiring evacuation of the station. In the event the train berths improperly the concept of operations should dictate that the train continue to the next station where it can berth properly to allow egress onto the platform. If for some reason, that cannot occur, egress from the improperly berthed train would through the 40 inch wide EEDs.

NFPA 101 2018, Section 7.2.1.4.3.1 and NYS BC 2015, Section 1005.7.1 door leaf encroachment is limited to 50% of the width of the egress path. Thus the door leaf width, 22 inches (assumption #3 above), becomes the determining factor in the minimum platform width. See figure 1 for side platforms and figure 2 for center platforms.

In the case of the side platform the width is measured from the face of the wall or any obstruction that occurs regularly at 15 feet on center or less to account for rows of columns that restrict widths in many stations. Benches and/or trash receptacles are episodic elements that are not considered an issue when they are sufficiently narrow and nested between columns. In the case of a continuous wall, benches and trash receptacles cannot reduce these minimums; they shall be located at platform ends, outside the path of travel, or located strategically after installation of the platform screen with EE door locations known. In the case of a row or rows of columns occurring within these minimum dimensions the total width of these columns shall be added to the minimums shown in figure 1 and figure 2.

We have examined open side and center platforms. If the side platform diagram (figure 1) were applied to all obstructions within 5' – 11" of the platform edge (including stairs other large obstructions) there will be a large number of stations that would not comply. Since an actual design of PSDs is beyond the scope of this study we cannot know if the distribution of stairs off the platform, or other adjustments can successfully address these egress issues. Therefore we recommend not applying these minimums to these situations at this time. For the purposes of this System Wide Survey we will only use these minimums in relation to the overall surveyed platform widths.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for IRT Flushing Line Stations in Queens

MTA/NYCT

July 5, 2018

BASIS OF ESTIMATE

1.0 ***Description of typical APG / PSD installation:***

1.1 *APGs / PSDs will provide 43 emergency egress doors with push bars per platform*
1.2 *APGs will be 4'-6" foot high system cantilevered from the platform*
1.3 *Each platform edge will have 55 cameras for CCTV coverage; cameras tied to a central control facility via existing fiber backbone*
1.4 *Control Rooms will be as documented in the individual reports; walls will be 8 inch CMU with glazed ceramic tile on exterior/public side of the walls (if located on below grade platform)*
1.5 *Control Rooms will serve both platform edges unless otherwise indicated*
1.6 *Control Rooms will be cooled to maintain operability of the control equipment*
1.7 *Due to entrapment concerns (someone being trapped between the train doors and the APGs / PSDs) a laser sensor gap detection system will be included at 100% of the doors to assure that doors are clear before the train leaves the station*
1.8 *Stray current isolation will be required be means of grounding wires and non-conductive paint on columns; assume (42) 10" x 10" H columns will be painted to 10 feet above the platform finish; assume a grounding wire to negative running rail will be installed at three locations along the platform edge*

1.9 *Provide a network/system for centralized monitoring/control of door operations at the RCC. Communication with this system will be via the current Sonet/ATM (SACNS) or COE network potentially leveraging the existing PSLAN. The set-up of the head-end for such a system is a one-time cost, integration cost would be per station.*

2.0 ***Assumptions:***

2.1 In respect of the APG option, all platforms will require structural rehabilitation to take the anticipated loads.
2.2 In respect of the PSD option, only platforms that have not been upgraded in the recent past (assuming over the past two decades) will require platform edge replacement.
2.3 There are no special security requirements made necessary by installation of the APG system
2.4 It is assumed that all stations have adequate electrical power to satisfy the additional load required for the PSDs/APGs. In the event the power is inadequate, the electrical service would have to be upgraded at an additional cost.
2.5 This estimate does not provide for the replacement of Platform Edge Lighting
2.6 Premium cost for night time work is considered 50% of total labor cost

A CONSTRUCTION CONSULTING FIRM

Tier 2-3 Report on Feasibility of Platform Edge Barriers for IRT Flushing Line Stations in Queens

MTA/NYCT

July 5, 2018

BASIS OF ESTIMATE

3.0 *Exclusions - Costs not included in the estimate:*

3.1 Costs associated with construction of remote Control Rooms (at locations other than inside the station)

3.2 Costs associated with changes to train signals or systems

3.3 Costs associated with changes to the platform or the station to widen platforms locally to accommodate APGs along their entire length

3.4 Costs associated with NYCT State Of Good Repair improvements to the station

3.5 Costs associated with changes to stop signals that may be required to accommodate alternate train lengths.

3.6 For the purposes of this estimate it is assumed that there are no costs required to mitigate interference with police and emergency radio communications within the platform area due to the installation of APGs

3.7 Escalation Cost is not included; Anticipate at 5% per annum.

3.8 Costs associated with the removal of Asbestos-Containing Materials (ACM) are excluded from this estimate.

3.9 No provision has been included for the anticipated premium associate with tariffs on imported Structural Steel / Aluminium

3.10 NYCT project cost is not included

3.11 GO and flagging cost is not included

3.12 Maintenance / Operational Costs are not included. These will form part of a separate exercise

4.0 *Below the line or "soft" costs:*

4.1 Design and Construction Contingency

4.2 Contractor O & P

4.3 Insurance

4.4 NYCT project costs not included

5.0 *Additional Notes*

5.1 *Given the limited time available, no drawings were developed to support this estimate.*

ITEM	DESCRIPTION OF WORK	UNIT QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] SIDE 01=	628	LF		
5	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] SIDE 02=	594	LF		
6	LENGTH OF THE PLATFORM EDGE [FLUSHING BOUND] SIDE 01=	592	LF		
7	LENGTH OF THE PLATFORM EDGE [FLUSHING BOUND] SIDE 02=	621	LF		
8	TOTAL LENGTH OF THE PLATFORM EDGE =	2,435	LF		
9					
10	AUTOMATIC PLATFORM GATES [APG's]				
11					
12	Platform edge reconstruction				
13	Demolition				
14	Remove existing polyethylene edge strip	2,435	LF	7	17,045
15	Remove 5' wide section of 3" deep structural slab to platform edge	12,175	SF	12	146,100
16	New Work				
17	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	245	CY	2,500	612,500
18	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	2,439	EA	25	60,975
19	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	2,439	EA	25	60,975
20	Cast in assemblies for PSD holding down bolts	1,408	EA	180	253,440
21	Polyethylene edge strip	2,435	LF	95	231,325
22	Provide sleeves for HV & LV wires	720	EA	110	79,200
23					
24	Platform edge finishes				
25	Demolition				
26	Remove existing tactile warning strip 2' wide	2,435	LF	15	36,525
27	Remove existing platform tiles	2,435	LF	12	29,220
28	Sawcut existing topping concrete at perimeter of removal area	2,435	LF	5	12,175
29	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	14,610	SF	8	116,880
30	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 17'-8" wide strip at ADA boarding area	498	SF	8	3,985

STATION: FLUSHING-MAIN STREET

ITEM	DESCRIPTION OF WORK	UNIT QTY	MEAS	UNIT COST	TOTAL STATION COST
31	New Work				
32	New concrete topping to match existing	2,435	SF	15	36,525
33	New concrete topping at ADA boarding area to match existing	498	SF	15	7,471
34	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	1,056	LF	110	116,160
35	Misc. patchwork	1	LS	50,000	50,000
36					
37	Equipment Room [14'-0" x 27'-0"]				
38	Build off existing platform slab		Note		
39	Form 8" wide concrete curb including dowelling to platform slab	82	LF	90	7,380
40	CMU Wall for equipment room	820	SF	45	36,900
41	Vertical connections with existing structure	-	LF	25	-
42	Fire rated door including frame & hardware	1	EA	2,500	2,500
43	Exterior wall finish				
44	Ceramic Tiling to match existing	820	SF	40	32,800
45	Mosaic Band to match existing - Assuming 8" high	82	LF	120	9,840
46	Concrete cove to match existing	82	LF	20	1,640
47	Interior Wall Finish - Paint	820	SF	5	4,100
48	Allow for Misc. floor & ceiling finishes	378	SF	15	5,670
49	Allow for 4" thick concrete pads for equipment	95	SF	20	1,890
50	Allowance for Mechanical Scope	1	LS	40,000	40,000
51	Allow for trench drains including associated pipework, cutting & patching, etc.	1	LS	60,000	60,000
52	Allow for Inergen Fire Suppression System incl. tanks, manifold, piping, discharge nozzles, signage, link to FA System	1	LS	100,000	100,000
53	Allowance to bring fiber optic to Control Room from network node	1	LS	15,000	15,000
55	Automatic Platform Gates [APGs] - 4'-6" High				
56	Automatic bi-parting gates; Assumed 6'-0" wide (11 Cars x 4 Doors = 44 No. per platform x #2)	176	EA	15,000	2,640,000
57	Hinged Emergency Escape Gates (EEGs) - Between the bi-parting doors; #43 per Platform	172	EA	10,500	1,806,000
58	Double egress/service gate in the center of the platform; #1 per Platform	4	EA	20,000	80,000
59	Platform End Gates (PEGs)	8	EA	13,000	104,000
60	Fixed Panels including framing and support; 4'-6" High	3,740	SF	750	2,804,625
61	Spare Parts - Approx. 10% of Material Cost	1	LS	446,078	446,078
62	Testing and commissioning	1,600	HRS	160	255,888
63	Product Warranty	1	LS	1,500,000	1,500,000
64	Allowance for Braille Signage	176	EA	2,500	440,000
65					
66	Electrical				
67	Electrical Upgrades				
68	Assumed adequate power is available to cater for additional load required by above scope		Note		EXCL.
69	Power and Lighting

Tier 2-3 Report on Feasibility of Platform Edge Barriers for IRT Flushing Line Stations in Queens

5-Jul-18

STATION: METS-WILLETS POINT

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [NORTH TRACK] SIDE 01 =	622	LF		
5	LENGTH OF THE PLATFORM EDGE [NORTH TRACK] SIDE 02 =	565	LF		
6	LENGTH OF THE PLATFORM EDGE [SOUTH TRACK] SIDE 01 =	569	LF		
7	LENGTH OF THE PLATFORM EDGE [SOUTH TRACK] SIDE 02 =	565	LF		
8	TOTAL LENGTH OF THE PLATFORM EDGE =	2,321	LF		
9					
10	AUTOMATIC PLATFORM GATES [APG's]				
11					
12	Platform edge reconstruction				
13	Demolition				
14	Remove existing polyethylene edge strip	2,321	LF	7	16,247
15	Remove 5' wide section of 3" deep structural slab to platform edge	11,605	SF	12	139,260
16	New Work				
17	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	233	CY	2,500	582,500
18	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	2,325	EA	25	58,125
19	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	2,325	EA	25	58,125
20	Cast in assemblies for PSD holding down bolts	1,408	EA	180	253,440
21	Polyethylene edge strip	2,321	LF	95	220,495
22	Provide sleeves for HV & LV wires	720	EA	110	79,200
23					
24	Platform edge finishes				
25	Demolition				
26	Remove existing tactile warning strip 2' wide	2,321	LF	15	34,815
27	Remove existing platform tiles	2,321	LF	12	27,852
28	Sawcut existing topping concrete at perimeter of removal area	2,321	LF	5	11,605
29	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	13,926	SF	8	111,408
30	Remove existing 3" concrete topping at 44' long ADA boarding area	1,958	SF	8	15,664
31	New Work				
32	New concrete topping to match existing	2,321	SF	15	34,815

5-Jul-18

STATION: METS-WILLETS POINT

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
33	New concrete topping at ADA boarding area to match existing	1,958	SF	15	29,370
34	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	1,056	LF	110	116,160

MTA/NYCT

Tier 2-3 Report on Feasibility of Platform Edge Barriers for IRT Flushing Line Stations in Queens

5-Jul-18

STATION: QUEENSBORO PLAZA

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	654	LF		
5	LENGTH OF THE PLATFORM EDGE [FLUSHING BOUND] =	588	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,242	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,242	LF	7	8,694
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,210	SF	12	74,520
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	125	CY	3	375
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,244	EA	25	31,100
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,244	EA	25	31,100
18	Cast in assemblies for PSD holding down bolts	704	EA	180	126,720
19	Polyethylene edge strip	1,242	LF	95	117,990
20	Provide sleeves for HV & LV wires	360	EA	110	39,600
21					
22	Platform edge finishes				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,242	LF	15	18,630
25	Remove existing platform tiles	1,242	LF	12	14,904
26	Sawcut existing topping concrete at perimeter of removal area	1,242	LF	5	6,210
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,452	SF	8	59,616
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 16' wide strip	880	SF	8	7,040
29	New Work				
30	New concrete topping to match existing	1,242	SF	15	18,630
31	New concrete topping at ADA boarding area to match existing	880	SF	15	13,200

STATION: QUEENSBORO PLAZA

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
32	Tactile Warning Strip - 2' wide strip along platform edge at door openings only & Platform end gates	528	LF	110	58,080

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	633	LF		
5	LENGTH OF THE PLATFORM EDGE [FLUSHING BOUND] =	639	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,272	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,272	LF	7	8,904
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,360	SF	12	76,320
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	128	CY	2,500	320,000
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,274	EA	25	31,850
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,274	EA	25	31,850
18	Cast in assemblies for PSD holding down bolts	704	EA	180	126,720
19	Polyethylene edge strip	1,272	LF	95	120,840
20	Provide sleeves for HV & LV wires	360	EA	110	39,600
21					
22	Platform edge finishes				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,272	LF	15	19,080
25	Remove existing platform tiles	1,272	LF	12	15,264
26	Sawcut existing topping concrete at perimeter of removal area	1,272	LF	5	6,360
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,632	SF	8	61,056
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Balance of platform width i.e. 12'-6" wide strip	572	SF	8	4,576
29	New Work				
30	New concrete topping to match existing	1,272	SF	15	19,080
31	New concrete topping at ADA boarding area to match existing	572	SF	15	8,580

STATION: VERNON BLVD - JACKSON AVE

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST

ITEM	DESCRIPTION OF WORK	QTY	UNIT MEAS	UNIT COST	TOTAL STATION COST
1	GENERAL NOTES				
2	The estimate detail (lines 1 through 134 below) lists the components of the Platform Screen Door installation with a description of each item, a Quantity, a Unit of Measure, a Unit Cost and a Total Station Cost. The Station Cost represents the cost of PSD's and associated ancillary scope to two platform edges and a single control room.				
3	On the Summary (page 7 and 8) the total of the estimated detail line items below appears as the Total Direct Cost at the top of Page 7. After adding general requirements, overhead & profit, bonds & insurance the construction cost is given. After adding design fees, the Project Cost for this Station and other stations studied is given. A range of contingencies is described on page 8 and Alternative Option Premiums on Page 9.				
4	LENGTH OF THE PLATFORM EDGE [MANHATTAN BOUND] =	600	LF		
5	LENGTH OF THE PLATFORM EDGE [FLUSHING BOUND] =	600	LF		
6	TOTAL LENGTH OF THE PLATFORM EDGE =	1,200	LF		
7					
8	AUTOMATIC PLATFORM GATES [APG's]				
9					
10	Platform edge reconstruction				
11	Demolition				
12	Remove existing polyethylene edge strip	1,200	LF	7	8,400
13	Remove 5' wide section of 3" deep structural slab to platform edge	6,000	SF	12	72,000
14	New Work				
15	Cast in place platform edge slab; Approx. 5'-0" wide x 6" minimum depth at cantilever edge	121	CY	2,500	302,500
16	Drill and adhere dowel to existing concrete wall [at platform edge]; #4 Dowel w/standard hook @ 12" O.C; 6" Embed	1,202	EA	25	30,050
17	Drill and adhere dowel to existing concrete structural slab; #4 Dowel w/standard hook @ 12" O.C	1,202	EA	25	30,050
18	Cast in assemblies for PSD holding down bolts	704	EA	180	126,720
19	Polyethylene edge strip	1,200	LF	95	114,000
20	Provide sleeves for HV & LV wires	360	EA	110	39,600
21					
22	Platform edge finishes				
23	Demolition				
24	Remove existing tactile warning strip 2' wide	1,200	LF	15	18,000
25	Remove existing platform tiles	1,200	LF	12	14,400
26	Sawcut existing topping concrete at perimeter of removal area	1,200	LF	5	6,000
27	Remove existing 3" concrete topping for platform edge re-construction; Assuming 6' wide strip	7,200	SF	8	57,600
28	Remove existing 3" concrete topping at 44' long ADA boarding area; Platform width i.e. 28'-6" wide strip at ADA boarding area	726	SF	8	5,808
29	New Work				
30	New concrete topping to match existing	1,200	SF	15	18,000
31	New concrete topping at ADA boarding area to match existing	726	SF	15	10,890

New York City Transit

REPORT ON FEASIBILITY OF PLATFORM EDGE BARRIERS FOR ‘A and C SERVICE STATIONS

CONTRACT #: C-32516 | STV PROJECT #: 3017214

FINAL SUBMITTAL DATE: August 8, 2019

STV 100 Years

Table of Contents

Appendices

Executive Summary

In our ongoing study of all 472 stations of NYCT, this report builds on the initial feasibility studies previously submitted. Previous studies include:

- A study to identify a location for a pilot installation of Platform Screen Doors (PSD) at a revenue station. A summary of the technology and feasibility criteria sections of that report is included in Appendix A of this report for reference.
- A structural study of typical platform construction and it's suitability for handling PSD loads across the NYCT system. That study is included for reference in Appendix B of this report.
- A study of the impact to station egress of platform screen doors: Appendix C

This system-wide study follows a Tier 1, 2, 3 methodology of progressively detailed analysis, with Tier 1 examining vehicles and generic characteristics, and Tier 2 and 3 looking at localized physical characteristics of individual stations. Our Tier 1 analysis found no instances of door misalignment between car classes for this line (Note that the Rockaway Park shuttle – a half-length train – will need to revise its stopping position to align with either the first or last five cars of the regular A-train). This Tier 2/3 report looks at issues of obstructions near the platform edge, platform width, structural constraints, location of the equipment room, and an evaluation of available power.

Of these 66 newly evaluated stations, 25 have been found to be not suitable for the installation of PSDs. (34th Street / 8th Ave and Nostrand Ave are only feasible for the C and A train respectively. They are both counted as "feasible" in the overall tally)

> *[Note: the term "PSD" is used to universally include both full-height and half-height barrier systems. The term "APG" (Automatic Platform Gate) refers only to half-height barriers]*

The following points summarize the major constraints to installing a PSD system:

- ADA clearance issues: the platform edge barriers are 15" wide. Where an existing object (wall, stair, and railing) is close to the platform edge, the addition of the PSD can further constrain the available space. Under the following conditions, PSDs are declared infeasible:
  - Limit the ability of a wheelchair to turn within a 5'-0" circle
  - Limit path of travel to less than a 32" pinch width (defined as an obstruction that measures less than 2'-0" longitudinally, i.e. columns)
  - Limit path of travel to be less than a 36" corridor as defined by the edge of a staircase, railing or room
- Insufficient space for the PSD equipment room: the equipment room can be built as one long room (7'-6" x 27') or two smaller rooms (7'-6" x 17'). Many stations do not have available space for these rooms.
- Platforms that are too narrow: due to the out-swinging emergency egress doors which are part of the PSD barrier, many platforms do not provide enough width to facilitate egress in an emergency. Please see Appendix C which provides a complete explanation of code requirements regarding the placement of these new barriers in an existing station environment.
- Structural considerations: existing pre-cast panels which are typically found at elevated platforms cannot support the added load of PSDs / APGs. The installation of PSDs at precast elevated platforms was a subject of analysis in the Structural Feasibility Report of April 2018 (See Appendix B). As noted there, PSDs would require full replacement of the platform thus changing the scope of a PSD project from an Alteration 2 to an Alteration 3 and triggering a full seismic

upgrade to the existing station structure. Such extensive work would not be in proportion to the benefit.

- Columns at platform edge: at certain stations, the columns are positioned 16" to 24" from the platform edge. While this dimension allows for the 15"-wide APG/PSD system, installation and maintenance cannot be carried out due to the lack of clear space.

Note that a determination of full feasibility will require two additional steps:

- Computational Fluid Dynamics (CFD) analysis; the installation of PSDs introduces a significant barrier to air flow at underground stations. Based upon CFD analyses done for the half-height automated platform gates (APGs) of the previously proposed 3rd Avenue pilot station, such installations are likely to be successful in underground stations. However, it is assumed if/when design of APG/PSDs are initiated at any future stations CFD analysis will be performed as part of the design process.
- An NFPA130 timed egress analysis for the existing stations or for potential PSD designs is also beyond the scope of this study, however a generic review of the impact of PSD installation on egress capacity (Appendix C) has informed the findings of this feasibility study. This conceptual review looked at the impact of PSDs on egress from the platform, especially the impact of the outward-swinging emergency egress doors which are part of the PSD system. The PSD barrier is approximately 15" in thickness; with the emergency egress doors in their outward swinging open position, the PSD barriers and doors collectively subtract 3'-1" from platform width. At certain narrow platforms, this reduction of width would exceed code-mandated limits. See Appendix C for more detail.

A garbage train is used for refuse removal at most of the A/C-line stations. For a PSD installation, it is proposed that keys be given to crew members so that they can manually open the typical PSD doors or emergency egress doors for the (off) loading of garbage carts. Per existing procedures, the distance between the driver's cabin and the first available slot for loading a garbage cart is constantly changing as the train proceeds through multiple stops. It will therefore not be possible to establish a unique stop marker for the garbage train; each instance of garbage pick-up will need the driver to stop at a different location, guided by personnel on the platform. This additional step in berthing the garbage train will likely negatively affect productivity for this activity. In addition, the currently-used metal garbage carts could potentially damage the PSD system during loading. This is evidenced in damage from these carts along walls adjacent to station refuse rooms. In conclusion, the implementation of a PSD system will likely require a re-design of the refuse removal process.

The table on the following page summarizes these findings and shows that platform edge barriers are feasible at 62% of the 'A' & 'C' Line Stations. Total implementation cost would be $1.5B for APGs and $1.3B for PSDs. An estimate of maintenance cost was performed for the proposed pilot station at 3rd Avenue; that estimate can reasonably be applied in the calculation of estimated maintenance costs at all two-platform stations. It shows an annual maintenance cost of $931,000 per station for the first three years of maintenance, (see Appendix D) therefore for the 41 feasible stations (plus six additional pairs of platforms at express stations), the aggregate annual maintenance cost would be $43.7M.

Summary Table

(62% Feasible 41/66)*

*MR164 and MR179 are both counted as feasible though only one of the two services is feasible at those stations

1.0 Station Assessments

1.01 – MR 143 | 207th Street Inwood

Summary: *207th Street Inwood Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 4'-8" (see figure 1).*

Description

207th Street Inwood Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The width of the platform ranges from 23'-8' to 25'-6". The corridor width adjacent to the permanent "CED SCRUBBER ROOM "structure at the north end of the platform shown in photo below, is 4'-8" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
207th Street Inwood Station

1.02 – MR 144 | Dyckman Street Station

Summary: *Dyckman Street Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

The Dyckman Street Station is a below-grade station with two mildly curved side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are columns evenly distributed along the platform edge measuring 3'-4" from the platform edge. The platform widths measure approximately 11'-8" throughout. On the southbound platform there are two ceiling-mounted conductor monitors and one signal located above the platform edge, with a vertical clearance of at least 6'-8". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northbound control area (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are nearly tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

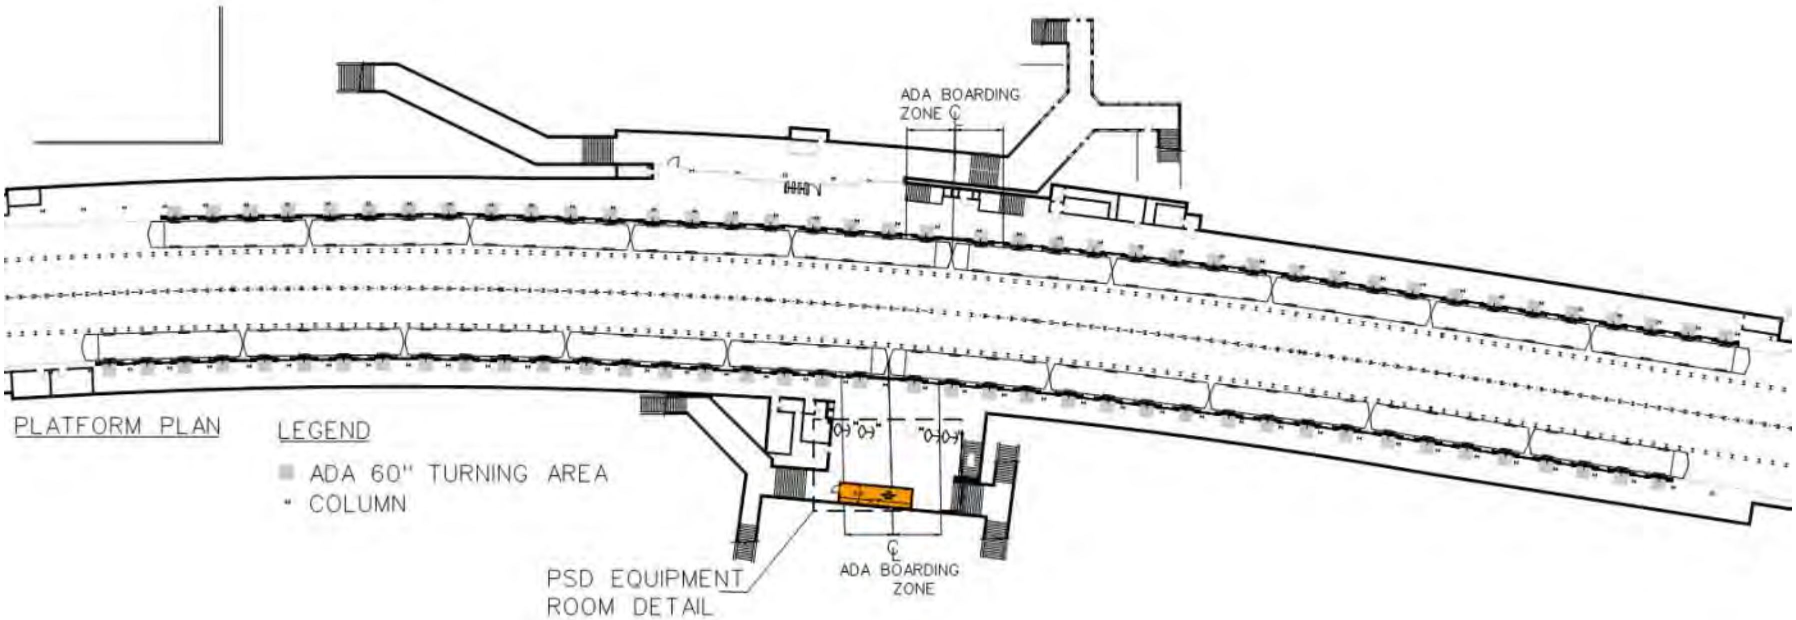

***Figure 1** – Overall plan*
Dyckman Street Station

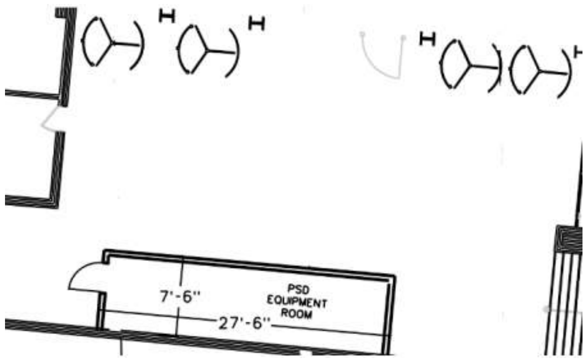

***Figure 2** – PSD Equipment Room Detail*
Dyckman Street 200th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear fluorescent fixtures mounted parallel to the platform edge. No alterations to the existing lighting configuration are anticipated.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal)

Station Name	Dyckman Street 200th St.
Peak Demand Load from ConEd Report, (kW)	60.4 (Combined)
Apparent Power (kVA)	75.5
Station Peak Demand Load, Max Current, (A)	209.7
Maximum Amount of Doors	80.0
PSD Total Load Including All Misc. Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	404
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	396
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 800A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve.

Dyckman Street Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.8M to install APGs and $41.3 to install PSDs (See Appendix E)

Table of Contents

1.03 – MR 145 | 190th Street Station

Summary: *190th Street Station is feasible for both APGs and PSDs. There is one ceiling-mounted signal located at the center of the northbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

The 190th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. The platforms are column-free with the exception of six columns at the center of each platform which are 3'-4" from the platform edge. The platform widths vary from approximately 12'-0" to 15'-8". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station mezzanine control area (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

Historic Restrictions:
The 190th Street station is a historically designated property. As such, design will require review by the New York State Historic Preservation Office.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.9M to install APGs and $41.1M to install PSDs (See Appendix E).

1.04 – MR 146 | 181st Street Station

Summary: *181st St Station is feasible for both APGs and PSDs. There is one ceiling-mounted signal located at the south end of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

The 181st St Station is a below-grade station with two mildly curved side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are seven columns at the northern end of the platforms measuring 3'-4" from the platform edge. The platform widths measure approximately 11'-8" throughout. Ceiling heights measure no less than 7'-6" throughout

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station's northern mezzanine (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are nearly tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.1M to install APGs and $41.2M to install PSDs (See Appendix E)

1.05 – MR 147 | 175th Street Station

Summary: *175th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

175th Street Station is a below-grade station with one center / island platform (**see Figure 1)**. The platform structure is cast-in-place concrete. Columns are distributed evenly along the center of the platform and measure 8'-7" from the platform edge. The platform width is approximately 19'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station's southern mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

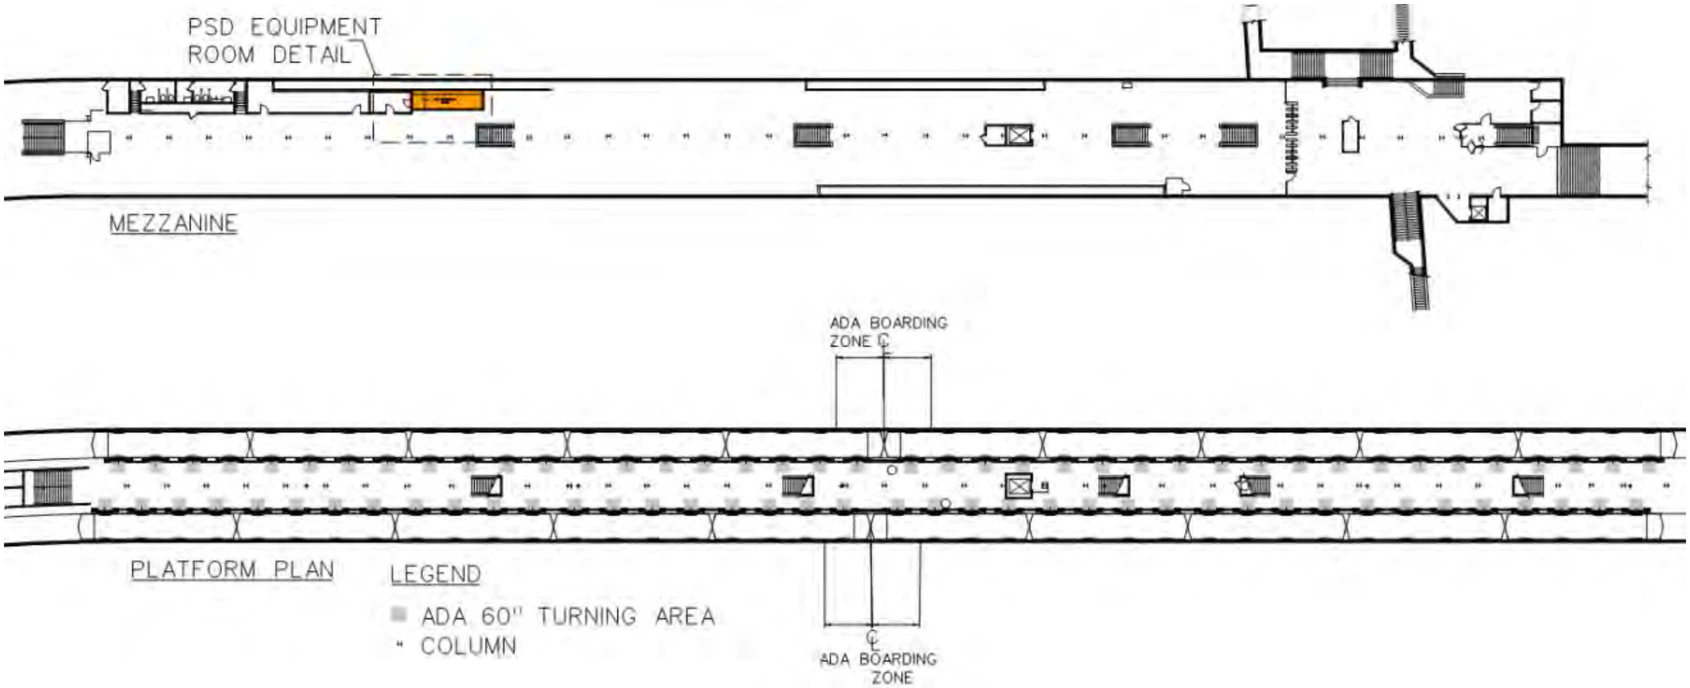

***Figure 1** – Overall Station Plan*
175th Street Station

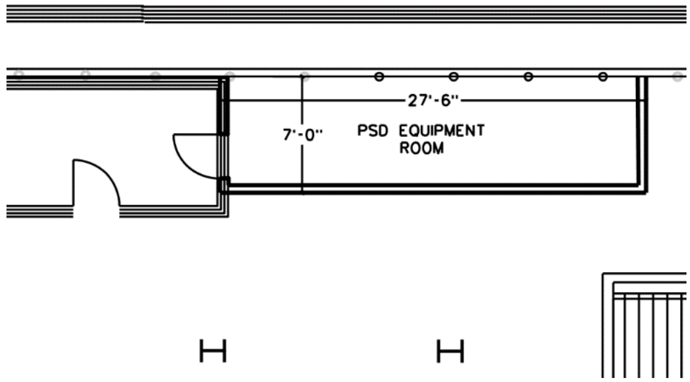

Figure 2 *– PSD Equipment Room Detail*
175th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal)

Station Name	175th Street
Peak Demand Load from ConEd Report, (kW)	75.2
Apparent Power (kVA)	94.0
Station Peak Demand Load, Max Current, (A)	261.1
Maximum Amount of Doors	80.0
PSD Total Load Including All Misc. Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	456
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	344
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 800A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve.

175th Street Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.9M to install APGs and $40.5M to install PSDs (See Appendix E).

1.06 – MR 148 | 168th Street Washington Heights

Summary: *168th Street Washington Heights Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the south end of the southbound platform as the existing width is 4'-4" (see figure 1).*

Description

168th Street Washington Heights Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms measures approximately 17'-4" throughout. The corridor width adjacent to the permanent "Car Equipment Cleaning Station "structure at the south end of the southbound platform shown in photo below, is 4'-4" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

***Figure 1** – Non-Compliant egress condition*
168th Street Station

Table of Contents

1.07 – MR 149 | 163rd Street

Summary: *163rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 27" (see figure 1).*

Description

163rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-8" throughout. The platforms are straight with two rows of columns measuring approximately 3'-6" from the platform edges. At the platform staircases, the columns measure 3'-6" from the platform edge and 1'-10" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 42" to 27" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
163rd Street Station

Table of Contents

1.08 – MR 150 | 155th Street

Summary: *155th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

155th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The platform widths are approximately 11'-10" throughout. The platforms are straight with two rows of columns measuring approximately 3'-4" from the platform edges. At the platform staircases, the columns measure 3'-4" from the platform edge and 0'-10" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
155th Street Station

1.09 – MR 151 | 145th Street (upper level)

Summary: *145th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

145th Street Station is a below-grade station with two levels of center / island platforms. The upper level serves the "A / C" trains and the lower level serves the "B / D" trains. The lower level of this station is addressed in prior reports for the B and D service. The platform structures are cast-in-place concrete.

The width of the upper platforms is approximately 22'-0" throughout. At staircases PL9 and P11 the columns are 20" from the staircase, and 40" from the southbound local platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum pinch point requirement of 32". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
145th Street

1.10 – MR 152 | 135th Street Station

***Summary:** 135th Street Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of both APG and PSD systems (see Appendix B). Existing power is adequate.*

Description

The 135th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the edges of the platform and measure 3’-4” from the platform edge. The platform width varies from approximately 7’-0” to 14’-8”. On each of the southbound and northbound platforms there is a ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7’-6”. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southern control area at the end of the northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27’-6” x 7’-0”.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would be required for the installation of both APG and PSD systems.

None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $30.6M to install APGs and $39.4M to install PSDs (See Appendix E).

1.11 – MR 153 | 125th Street

Summary: *125th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

125th Street St. Nicholas Ave. Station is a below-grade station with two center / island platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along the center of each platform and measure 8'-4" from the platform edge. The platform widths vary from approximately 17'-4" to 17'-10". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

Since there are four platform edges, two equipment rooms are required. The equipment rooms can be located at the center of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0" for each room.

Track Layout

Tracks are nearly tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $31.4M to install APGs and $40.7M to install PSDs. The cost of installation for the C-train for this station is estimated to be $31.4M to install APGs and $40.7M to install PSDs (See Appendix E).

Table of Contents

1.12 – MR 154 | 116th Street Station

Summary: *116th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 19" (see figure 1).*

Description

116th Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms range from approximately 2'-10" to11'-8". The width at the south end of the northbound platform is 34". The implementation of a platform edge barrier would reduce this already noncompliant width below the required minimum corridor requirement of 36". The remaining 19" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
116th Street Station

1.13 – MR 155 | 110th Street Station

Summary: *110th St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

110th St. Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-0' to 11'-8". The implementation of a platform edge barrier would reduce this lesser (already noncompliant) width below the required minimum corridor requirement of 36". The remaining 21" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

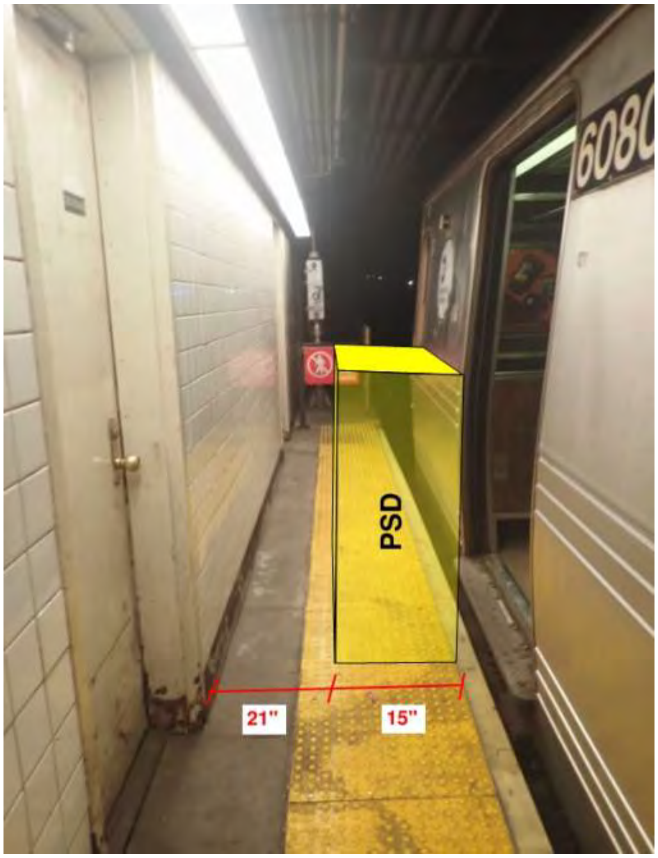

Figure 1 – Non-Compliant ADA condition
110th Street

1.14 – MR 156 | 103rd Street Station

Summary: *103rd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

103rd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 2'-4' to 10'-0". The implementation of a platform edge barrier would reduce this lesser (already noncompliant) width, below the required minimum corridor requirement of 36". The remaining 13" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
103rd Street

Table of Contents

1.15 – MR 157 | 96th Street Station

Summary: *96th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG or PSD system (see Appendix B). Existing power is adequate.*

Description

The 96th Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along each platform and measure 3'-4" from the platform edge. The platform widths vary from approximately 11'-8" to 12'-0". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northern control area at the end of the northbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would at a minimum be required for the installation of an APG or a PSD system.

1.17 – MR 159 | 81st Street Station

Summary: *81st St. Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

81st St. Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 3'-4' to 11'-10". The implementation of a platform edge barrier would reduce this lesser width below the required minimum corridor requirement of 36". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
81st St. Station

Table of Contents

1.18 – MR 160 | 72nd Street Station

Summary *72nd Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant egress conditions. In the implementation of a platform edge barrier, the 5'-11" minimum corridor requirement for evacuation would not be met at the north end of the southbound platform as the existing width is 4'-8" (see figure 1).*

Description

72nd Street Station is a below-grade station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms ranges from 4'-8' to 11'-10". The north end of the southbound platform in the photo below, is 4'-8" in width. Our station egress analysis (attached as Appendix C) finds that 5'-11" is a minimum side platform width which will not impede egress with an installed PSD system. See figure 1 for reference.

Figure 1 – Non-Compliant ADA condition
72nd Street Station

1.19 – MR 161 | 59th Street Columbus Circle Station

Summary: *59th Street Columbus Circle Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32” minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21” (see figure 1).*

Description

59th Street Columbus Circle Station is a below-grade station consisting of two center / island platforms (there is a third island platform which is closed to the public). The platform widths vary from approximately 10’-8” – 29’-0”. The platforms are mildly curved with two rows of columns approximately 3’-4” from edge of platform. At the platform staircases, the columns measure 3’-0” from the platform edge and 2’-2” from the staircase (see figure 1 for reference).The implementation of a platform edge barrier would reduce the currently compliant width of 36” to 21” or less* which would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

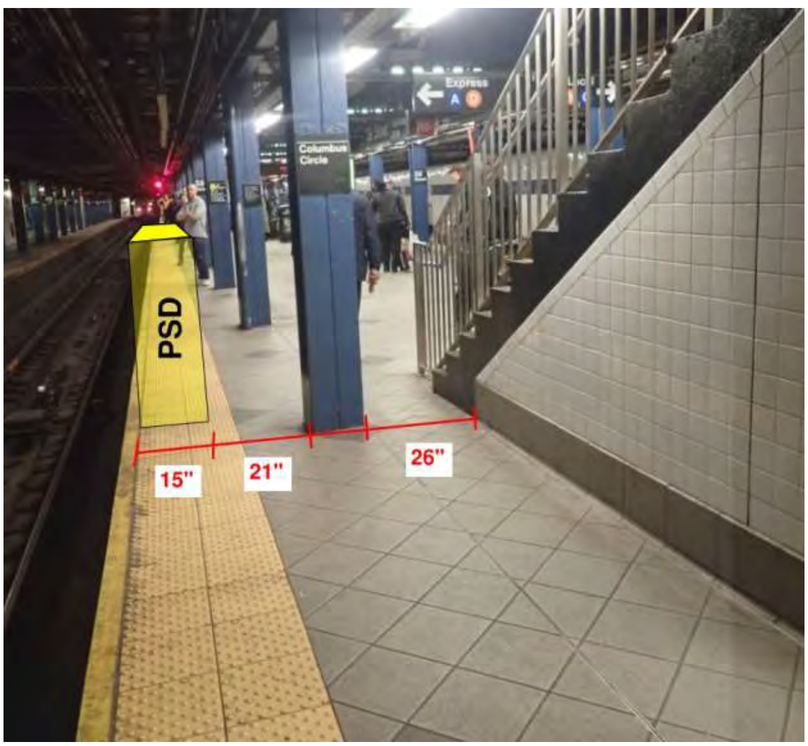

Figure 1 *–platform*
59th Street Columbus Circle Station

1.20 – MR 162 | 50th Street Station (Upper level)

Summary: *50th Street Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both an APG and PSD system (see Appendix B). There are three ceiling mounted signals located at the platform edge which would require relocation to implement a full height PSD system. Existing power is adequate.*

Description

The 50th Street Station is a below-grade station with two levels of straight side platforms **(see Figure 1)**. The upper level services the 8th Avenue "A / C" line and the lower level services the Queens Boulevard "E" line. This report concerns the upper level only; the lower level of this station is addressed in the E-train report. The platform structures are cast-in-place concrete. Columns are distributed evenly along the edges of the platform and measure 3'-4" from the platform edge. The platform widths vary from approximately 7'-2" to 15'-8". Ceiling heights measure no less than 7'-6" throughout. There is one signal near the southbound platform edge at a height of 7'-6", and two signals at the northbound platform edge at 7'-6" above floor.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the northern closed control area at the end of the northbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would be required for both the installation of an APG and a PSD system.

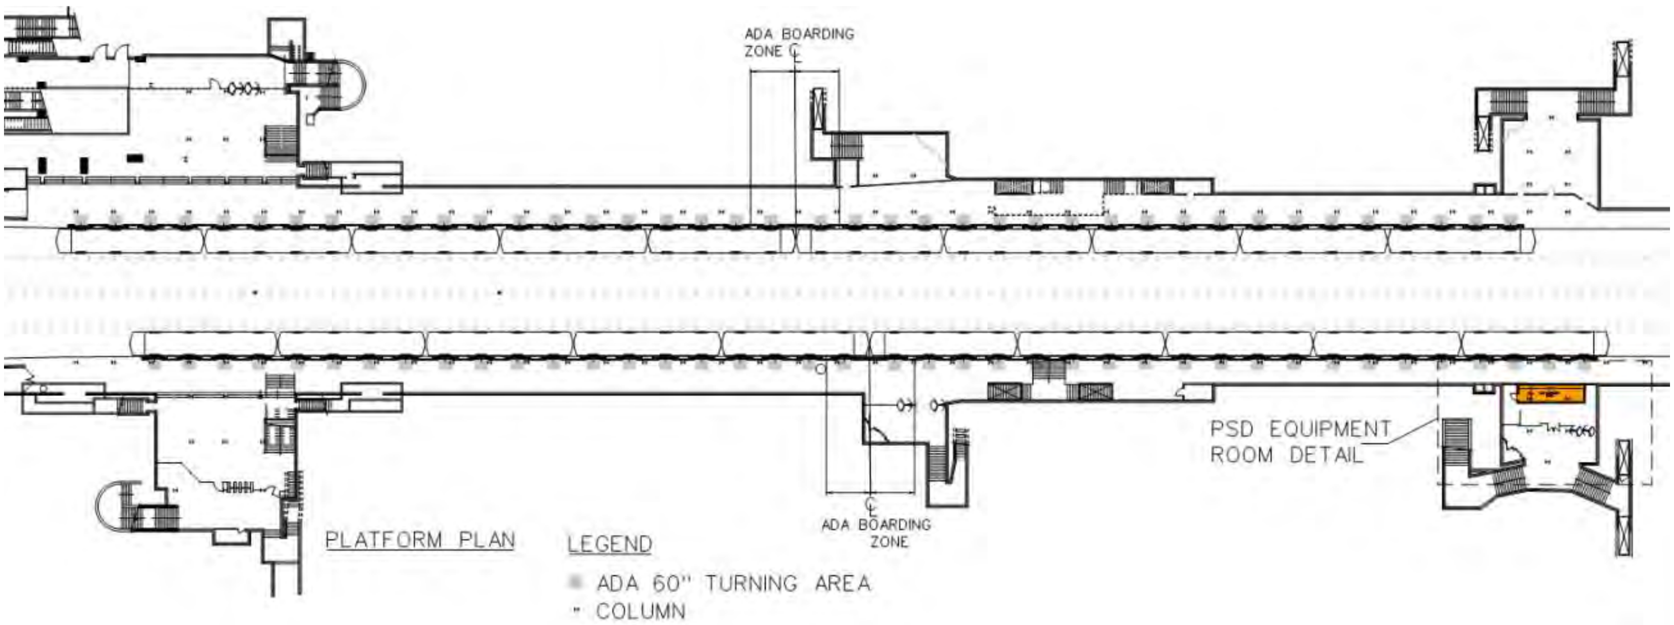

***Figure 1** – Overall Station Plan*
50th Street Station (Upper level)

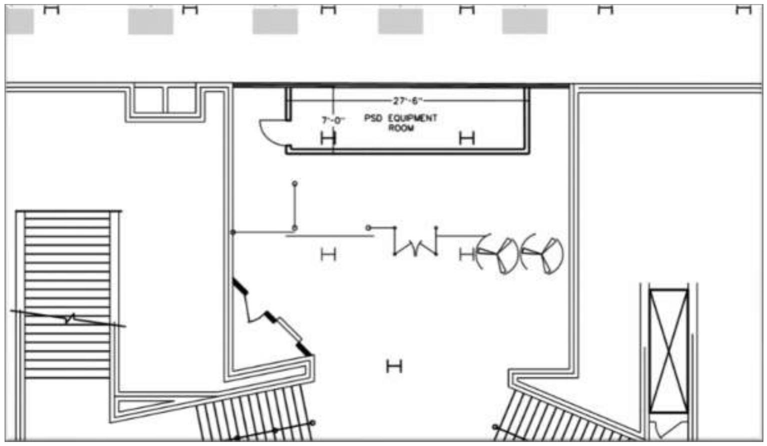

Figure 2 *– PSD Equipment Room at abandoned control area*
50th Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal)

Station Name	50th Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	96.0
Apparent Power (kVA)	120.0
Station Peak Demand Load, Max Current, (A)	333.3
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	674
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	526
Is Electrical Service Adequate?	**Yes**
Notes	Analysis is based on 1 line diagram. The station has (2) separate meters with combined meter reading. (Services indicate 1200 A fuses at service switches)

Table 1. Power Capacity Analysis

Historic Restrictions:
None.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions is listed in the attached ROM estimate. The total cost for this station is estimated to be $32.0M to install APGs and $42.3M to install PSDs (See Appendix E).

Figure 3 *– Typical platform view*
50th Street Station (upper level)

1.21 – MR 163 | 42nd Street Port Authority Station

Summary: *42nd Street Port Authority Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA complaint wheelchair movement would not be met at the ramp locations on both platforms. Wheelchair paths at the ramp locations would be constricted to less than 25".*

Description

42nd Street Port Authority Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the southbound platform is approximately 35'-0" throughout tapering down to 16'-3" towards the northern end. The width of the northbound platform is approximately 29'-0" throughout tapering down to 24'-0" towards the southern end. There is one ramp along the southbound platform which would constrain wheelchair movement with PSDs installed. Columns are spaced 15' on center with column faces 3'-4" away from all platform edges. The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 25" or less* would not allow for ADA compliant wheelchair movement. **(see Figure 1)**.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains

Figure 1 – *Non-Compliant ADA condition at ramp 42nd Street Port Authority*

1.22-A – MR 164 | 34th Street Penn Station (A-Train Island Platform)

Summary: *34th Street Penn Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

34th Street Penn Station is a below-grade station with two straight side platforms servicing the "C&E" lines and a single center / island platform servicing the "A" line. The side platforms are addressed in the subchapter on the following page (1.22-C – MR 164 | 34th Street Penn Station (C-Train Side Platform).

The center / island platform structure is cast-in-place concrete. The platform width is approximately 23'-8" throughout. The platform is straight with two rows of columns measuring approximately 3'-4" from the platform edges. At the southern staircase, the columns measure 3'-4" from the platform edge and 0'-6" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
34th Street Penn Station

1.22-C – MR 164 | 34th Street Penn Station (C-Train Side Platform)

Summary: *34th Street Penn Station is feasible for both APGs and PSDs. There are two ceiling mounted signals located above the each platform edge which would require relocation to implement an APG or PSD system. Platform structural work would be required to support the requirements of an APG system (see Appendix B). Existing power is inadequate. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

34th Street Penn Station is a below-grade station with two straight side platforms and one center/island platform **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 4'-0" from the platform edge. The southbound side platform width varies from approximately 11'-8" to 12'-0" throughout. The northbound side platform width is approximately 11'-6" throughout. On each platform there are two ceiling mounted monitors located above the platform edge, with a vertical clearance of at least 7'-4" **(see Figure 4)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted monitors located above the platform edge would need to be relocated in the implementation of full height PSDs (see figure 3).

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the central station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

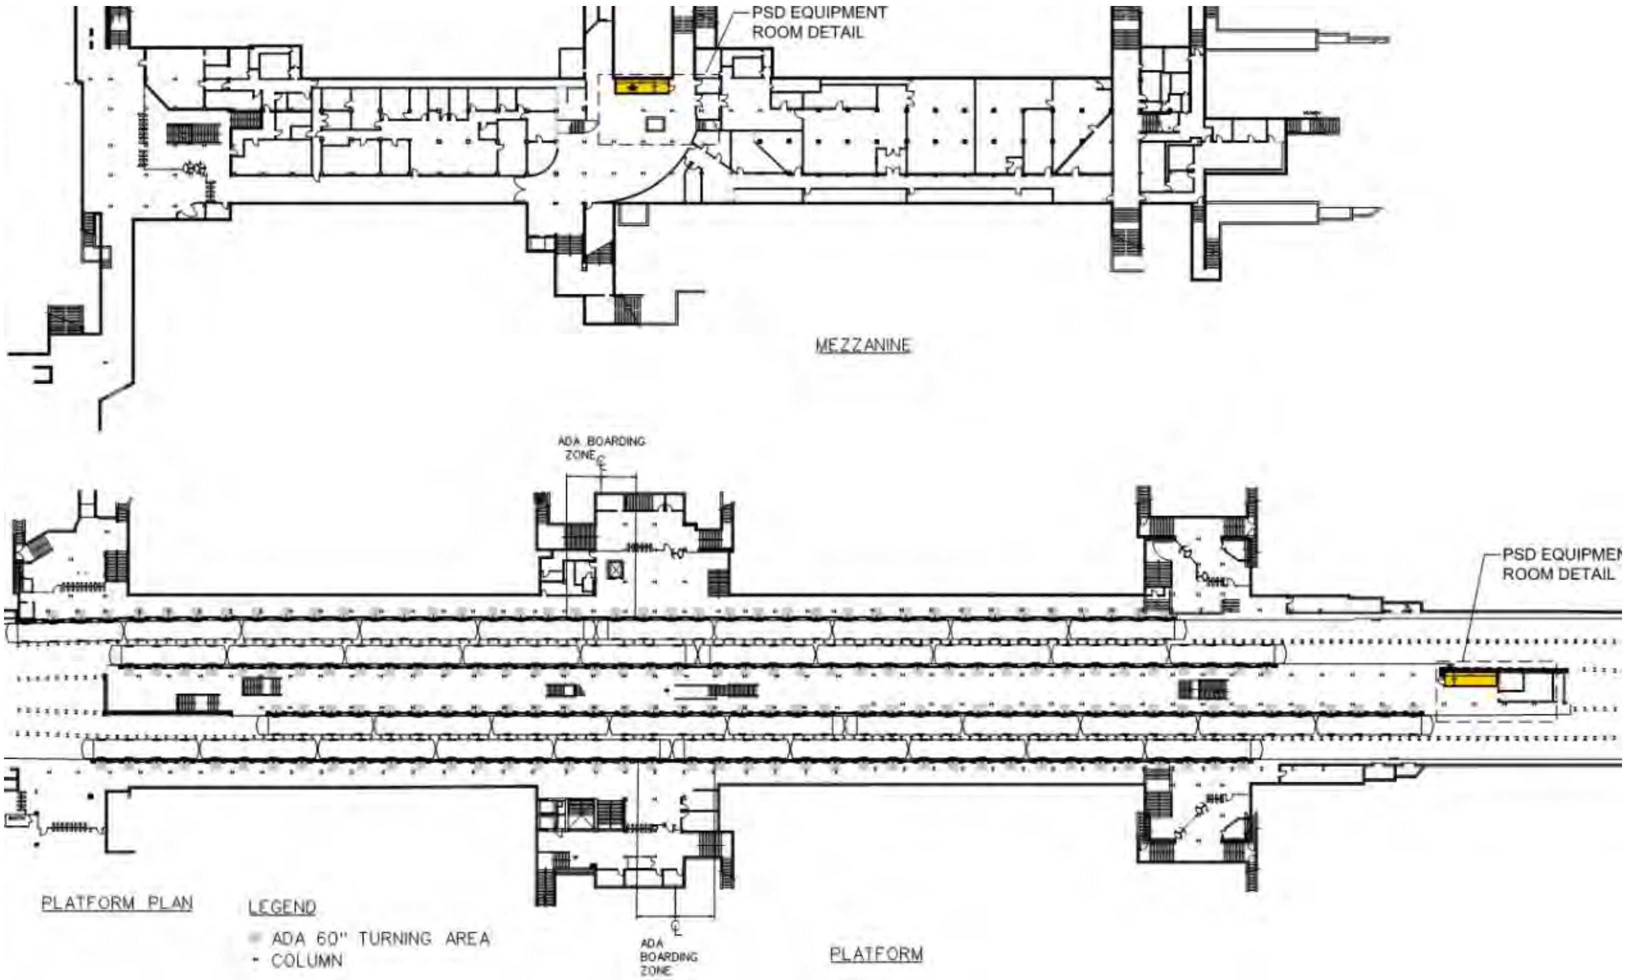

***Figure 1** – Overall Station Plan*

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.0M to install APGs and $40.3M to install PSDs (See Appendix E)

1.23 – MR 165 | 23rd Street Station

Summary: *23rd Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at the north end of the southbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

23rd Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound side platform width varies from approximately 11'-10" to 17'-8". The northbound side platform width is also approximately 11'-6" to 17'-8". On the north end of the southbound platform there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-6" **(see Figure 3)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted monitors located above the platform edge would need to be relocated in the implementation of full height PSDs (see figure 3).

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting..

Equipment Room

The equipment room could be located at the north end of the southbound platform, flush to the wall (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would be required for the installation of both an APG and a PSD system.

It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.0M to install APGs and $40.8M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with signal light*
23rd Street Station

1.24 – MR 166 | 14th Street -Eighth Avenue Station

Summary: *14th Street Station is feasible for both APGs and PSDs. The A line utilizes the inner edges of the two center / island platforms. The C and E lines utilize the outer edges. There are two ceiling mounted signals located on each platform which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is not adequate. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.*

Description

14th Street Station is a below-grade station with two straight center / island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 10'-9" from the platform edge. The southbound platform width varies from approximately 21'-4" to 22'-4". The northbound platform width also varies from approximately 21'-4" to 22'-4". On both platforms there are two ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7'-4". Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, standard NYCT wayfinding signage, and ceiling mounted monitors. A signal light will need to be re-positioned to facilitate installation of a full-height system.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting..

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the south end of the mezzanine, adjacent to staircase P18 (**see Figure 1, Figure 2 & Figure 3)**. The proposed room dimensions are 27'-0" x 6'-6" each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge was reconstructed in the 1990's. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge work would at a minimum be required for the installation of an APG system.

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $32.3M to install APGs and $41.8M to install PSDs. The cost of installation for the C-train for this station is estimated to be $32.3M to install APGs and $41.4M to install PSDs (See Appendix E).

***Figure 4** – Typical platform view with signal light*
14th Street Station

Table of Contents

1.25 – MR 167 | West 4th Street Station

Summary: *West 4th Street Station is feasible for both APGs and PSDs. Note that only the upper 8th Avenue platforms were evaluated for this report; the lower 6th Avenue platforms were evaluated in separate reports for the B, D, F, M, train services.*
There are two ceiling mounted signals located at the northbound platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see Appendix B). Existing power is not adequate. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Description

West 4th Street Station is a below-grade station with two levels of center / island platforms **(see Figure 1)**. This report covers only the upper level platforms which serve the A & C lines (and the E line covered in a separate report). The lower level platforms serving the B,D,F,M lines were found to be infeasible due to misalignment of train car doors.

The upper level platform structures are cast-in-place concrete. The platform columns are spaced 15’-0” on center, and column faces typically measure 3’-4” from platform edge. The northbound platform width measures approximately 25’-6” throughout. The southbound platform width measures approximately 27-2” throughout. On the southbound platform there are two ceiling mounted signals located above the platform edge, measuring no less than 7’-4” above the ground the **(see Figure 4)**. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting..

Equipment Room

Since there are 4 platform edges at the upper level of this station, 2 full size equipment rooms would be required. The equipment rooms could be located in the mezzanine (**see Figure 1, Figure 2 & Figure 3).** The proposed room dimensions are 27’-0” x 6’-6” each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Historic Restrictions:
West 4th Street Station is a historically designated property. As such, design will require review by the New York State Historical Preservation Office.

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $32.4M to install APGs and $41.0M to install PSDs. The cost of installation for the C-train for this station is estimated to be $32.4M to install APGs and $41.0M to install PSDs (See Appendix E).

***Figure 4** – Typical platform view with signal light*
West 4th Street Station

1.26 – MR 168 | Spring Street Station

Summary: *Spring Street Station is feasible for both APGs and PSDs. There is one ceiling mounted signal located at each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG or a PSD system (see structural report; Appendix B). Existing power is adequate.*

Description

Spring Street Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15'-0" on center with column faces approximately 3'-6" from the platform edge. The southbound side platform width varies from approximately 11'-8" to 17'-8". The northbound side platform width varies from 11'-8" to 17'-0". On both platforms there is one ceiling mounted signal located above the platform edge, with a vertical clearance of at least 7'-5" **(see Figure 3)**. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage. Ceiling mounted signals located above the platform edge would need to be relocated in the implementation of full height PSDs **(see Figure 3).**

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting..

Equipment Room

The equipment room could be located at the north end of the northbound platform, flush to the wall adjacent to staircase P14 (**see Figure 1, Figure 2)**. The proposed room dimension is 27'-0" x 6-6".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges appear to be original to the station construction. From our limited visual inspection and our knowledge of original station construction, structural work would be required for the installation of both an APG and a PSD system.

Table of Contents

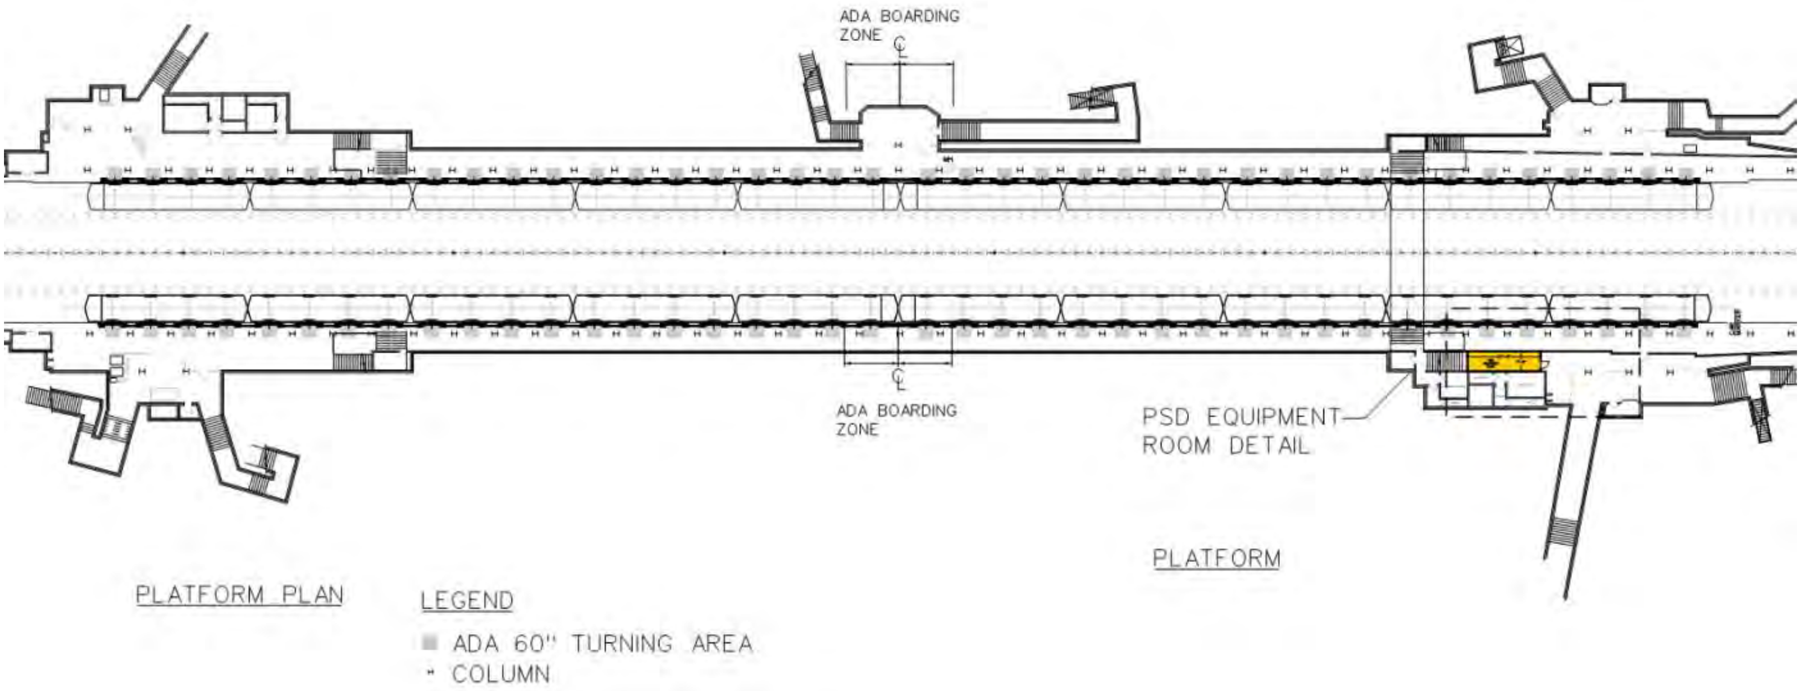

***Figure 1** – Overall Station Plan*
Spring Street Station

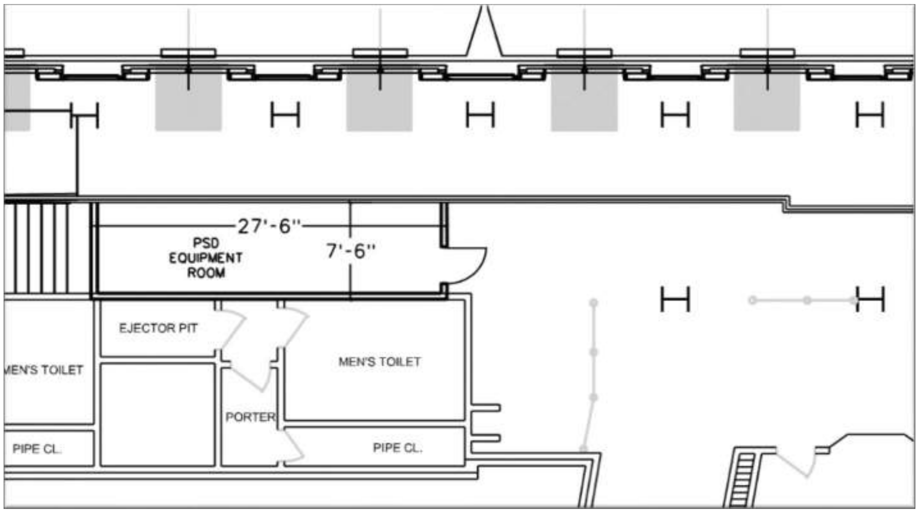

***Figure 2** – PSD Equipment Room 1 Detail*
Spring Street Station

Platform obstructions within 5' of edge:
Southbound Track:

- Columns

Northbound Track:

- Columns

Please note that in the ADA boarding zones there are existing conditions where there are columns obstructing the 60" circle requirement discussed in the ADA summary in Appendix A, the installation of a PSD system would not further exacerbate these conditions.

Lighting:
Existing lighting: Throughout both platforms; linear florescent; parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:
This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal)

Station Name	Spring Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	80.4
Apparent Power (kVA)	100.5
Station Peak Demand Load, Max Current, (A)	279.2
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	474
Station Service Power Capacity, (Main SB or SG Rating), (A)	1200
Service Spare Capacity, (A)	726
Is Electrical Service Adequate?	**Yes**
Notes	Analysis is based on 1 line diagram. The station has (2) separate meters with combined meter reading.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.1M to install APGs and $41.6M to install PSDs (See Appendix E)

***Figure 3** – Typical platform view with signal light*
Spring Street Station

1.27 – MR 169 | Canal Street Station

Summary: *Canal Street Station is feasible for both APGs and PSDs. There are three ceiling mounted signals located on each platform which would require relocation to implement a full height PSD system. Platform structural work would be required to support the requirements of an APG system (see structural report; Appendix B). Existing power is adequate.*

Description

Canal Street Station is a below-grade station with two straight center/island platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. Columns are spaced 15’-0” on center with column faces approximately 10’-6” from the platform edge. The southbound platform width varies from approximately 15’-6” to 22’-4”. The northbound platform width varies from approximately 19’’-6” to 22’-2”. On both platforms there are three ceiling mounted signals located above the platform edge, with a vertical clearance of at least 7’-1” **(see Figure 4)**. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be located in coordination with existing or replacement lighting..

Equipment Room

Since there are 4 platform edges at this station, 2 full size equipment rooms would be required. The equipment rooms could be located at the center of the mezzanine, flush to one of the walls of the mezzanine (**see Figure 1, Figure 2 & Figure 3)**. The proposed room dimensions are 27’-0” x 6’-6” each.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed in the 1990s. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations of the last thirty years, reconstruction of the concrete platform edge will be required at a minimum for the installation of an APG system.

Canal Street Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms; linear florescent; perpendicular to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Table 1 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Reserve)

Station Name	Canal Street
Peak Demand Load from ConEd Report, Last 20 Months, (kW)	90.4
Apparent Power (kVA)	113.0
Station Peak Demand Load, Max Current, (A)	313.9
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.8
Total Load (Station Peak + PSD), (A)	655
Station Service Power Capacity, (Main SB or SG Rating), (A)	800
Service Spare Capacity, (A)	145
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram. Station has (2) separate meter reading, for each Normal & Reserve service.

***Table 1**- Power Capacity Analysis*

Historic Restrictions:

None

Rough Order-of-Magnitude Cost Estimate:

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $31.9M to install APGs and $42.6M to install PSDs. The cost of installation for the C-train for this station is estimated to be $31.9M to install APGs and $42.6M to install PSDs (See Appendix E).

***Figure 4** – Typical platform view with signal light*
Canal Street Station

1.28 – MR 170 | Chambers Street Station

Summary: *Chambers Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 25" (see figure 1).*

Description

Chambers Street Station is a below-grade station consisting of one center / island platform. The platform width varies from approximately 15'-0" to 25'-4". The platform is mildly curved with two rows of columns approximately 3'-6" from edges of platform. At the platform staircases, the columns measure 3'-4" from the platform edge and are flush to the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 40" to 25" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-compliant ADA dimension*
Chambers Street Station

Table of Contents

1.29 – MR 172 | Fulton Street Station

Summary: *| Fulton Street Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

Fulton Street Station is a below-grade station with one center / island platform (**see Figure 1)**. The platform structure is cast-in-place concrete. Columns are distributed evenly along the platform and measure 2'-8" from the platform edge. The platform widths measure approximately 22'-0" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the center of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.9M to install APGs and $40.2M to install PSDs (See Appendix E).

Table of Contents

1.30 – MR 173 | High Street Station

Summary: *High Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 13" (see figure 1).*

Description

High Street Station is a below-grade station with one straight center / island platform. The platform structure is cast-in-place concrete. The platform width is approximately 19'-4" throughout. The platform is straight with two rows of columns measuring approximately 2'-6" from the platform edges. At the platform ends, the columns measure 2'-4" from the platform edge and 0'-6" from the staircase. The implementation of a platform edge barrier would reduce the currently non-compliant width of 28" to 13" or less* which would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 *– Non-Compliant ADA condition*
High Street Station

1.31 - MR-174 | Jay Street Metrotech

Summary: *Jay Street-MetroTech Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch width requirement for ADA compliant wheelchair movement would not be met at several stairs on both platforms. These stairs are not centered on the width of the platform, but are closer to the 'A' and 'C' track side of the platform. In these conditions, the remaining width would be 27" (see figure 1).*

Description

Jay Street-MetroTech Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The width of the platforms is approximately 24'-8" throughout. Columns are spaced 15'-0" on center with column faces 3'-6" away from the platform edge. On both platforms, column faces are 3'-6" from the platform edge. Currently, there is an ADA-compliant path of travel between columns and the platform edge (3'-6"). The implementation of a platform edge barrier would reduce this width below the required minimum of 32". The remaining 27" or less* would not allow for ADA compliant wheelchair movement.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

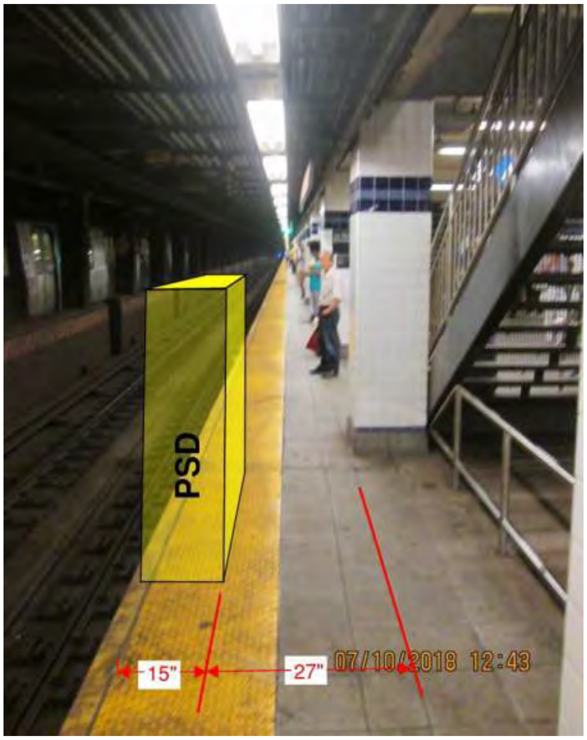

Figure 1 Non-Compliant ADA condition at stairs

1.32 – MR 175 | Hoyt Schermerhorn Station

Summary: *Hoyt Schermerhorn Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum requirement for ADA complaint wheelchair movement would not be met at all stairs as the remaining width would be 25" (see Figure 1). This condition occurs at multiple stairs on both station platforms.*

Description

Hoyt Schermerhorn Street Station is a below-grade station with four straight center / island platforms - two open revenue platforms in the center and two abandoned platforms on the sides. The platform structures are cast-in-place concrete. The width of the platforms is approximately 20'-6" throughout tapering down to 16'-10" at the southern end of the station. There are three staircases along each revenue platform. These staircases are centered on the platform and flanked on both sides by the typical station columns, where the column face is 3'-4" away from adjacent platform edge. Passengers requiring an ADA-compliant path of travel can currently move along the platform in the 3'-4" between columns and the platform edge. As seen in Figure 1, the implementation of a platform edge barrier would reduce this width below the required minimum of 32" for pinch-points. The remaining 25" or less* would not allow for ADA-compliant wheelchair movement.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

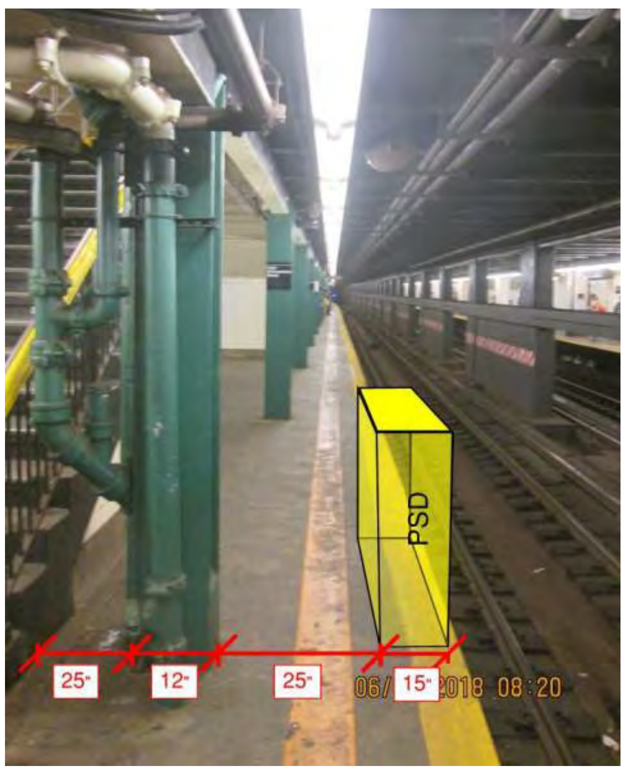

Figure 1: *Non-Compliant ADA condition at stairs (typical on all platforms)*
Hoyt Schermerhorn Street Station

1.33 – MR 176 | Lafayette Avenue Station

Summary: *Lafayette Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

The Lafayette Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

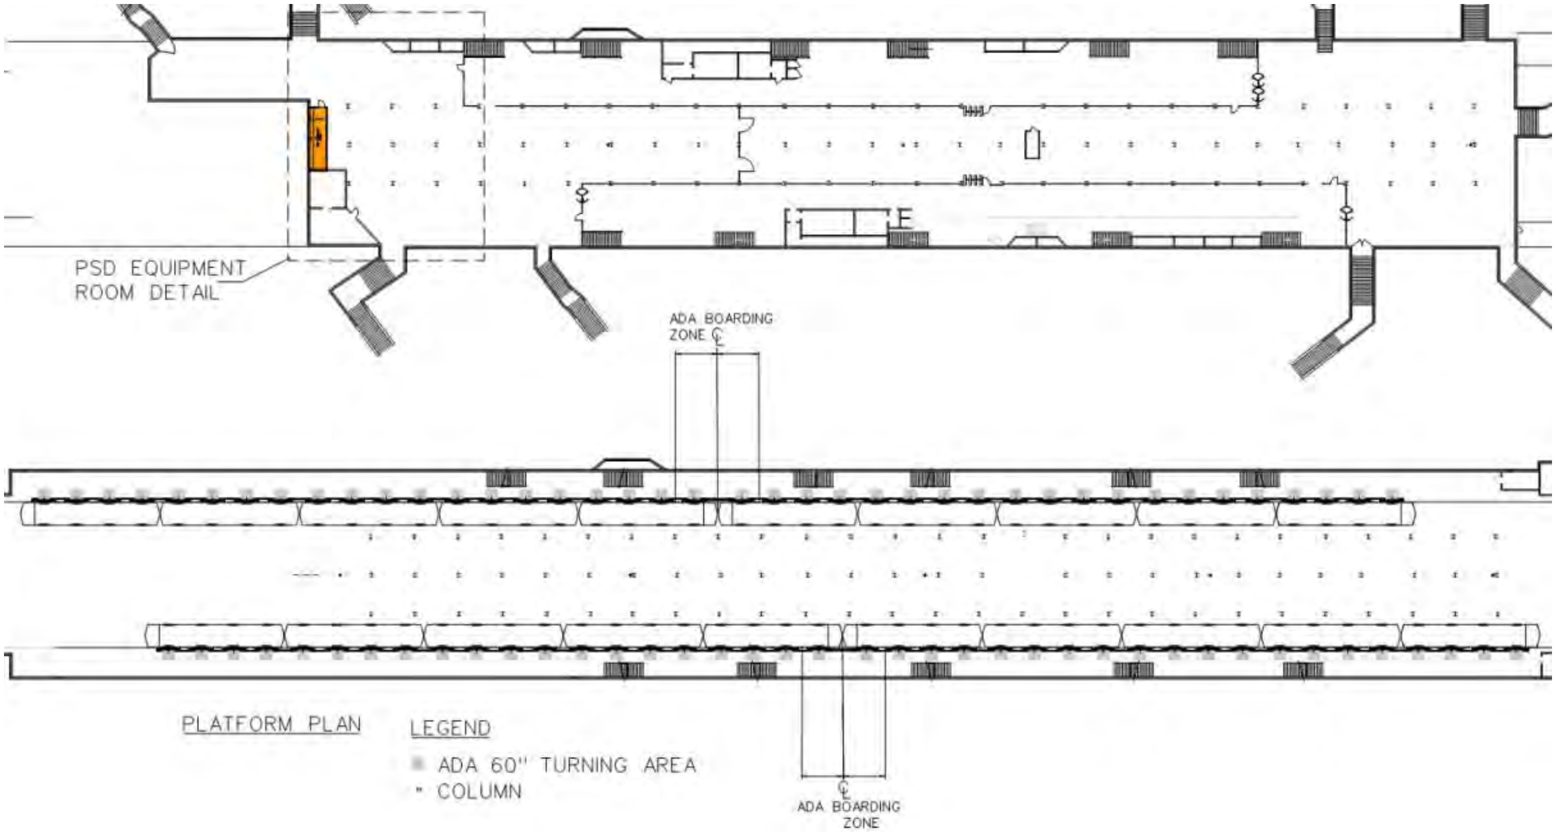

***Figure 1** – Overall plan*
Lafayette Avenue Station

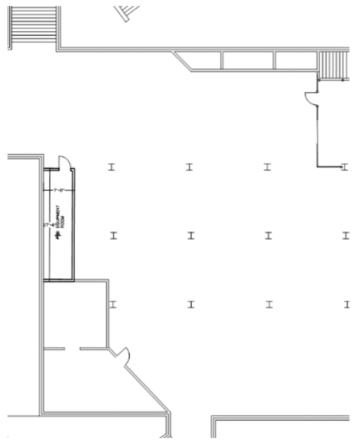

Figure 2 *– PSD Equipment Room Detail*
Lafayette Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal)

Station Name	Lafayette Ave.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.0M to install APGs and $40.8M to install PSDs (See Appendix E).

1.34 – MR 177 | Clinton Washington Avenue Station

Summary: *Clinton Washington Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Clinton Washington Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths vary measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound control area (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

1.35 – MR 178 | Franklin Avenue Station

Summary: *Franklin Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both an APG and PSD system (see Appendix B). Existing power is adequate.*

Description

The Franklin Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platforms. The platform widths measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the closed exit on the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

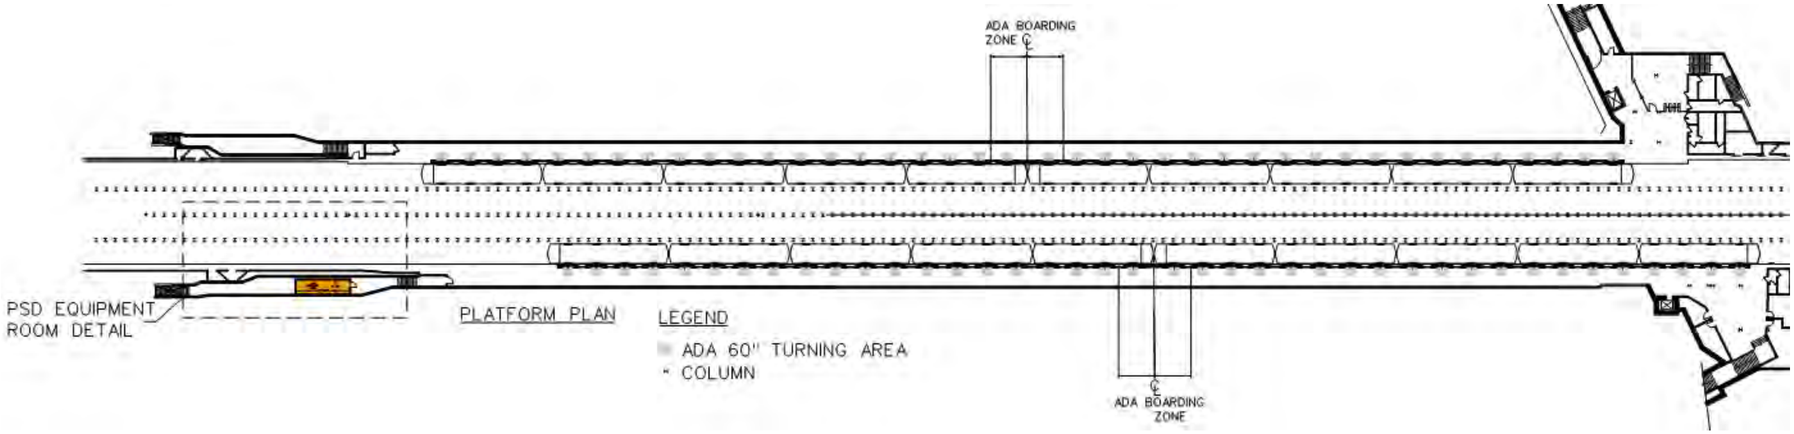

Figure 1 *– Overall plan*
Franklin Avenue Station

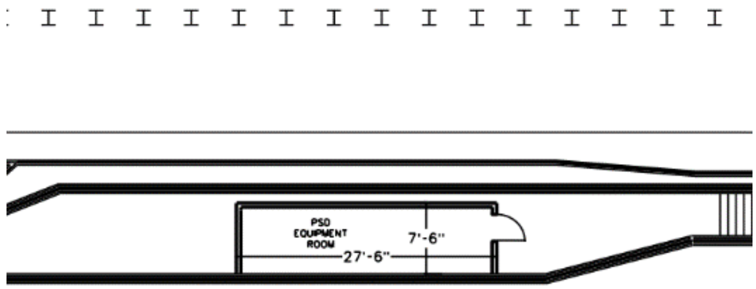

Figure 2 *– PSD Equipment Room Detail*
Franklin Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Franklin Avenue
Peak Demand Load from ConEd Report, (kW)	38.4
Apparent Power (kVA)	48.0
Station Peak Demand Load, Max Current, (A)	133.3
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	328
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	472
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 800A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve.

None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.0M to install APGs and $40.8M to install PSDs (See Appendix E).

1.36-A – MR 179 | Nostrand Avenue Station (Upper level)

Summary: *Nostrand Avenue Station is a two-level station, with the A-train service on the upper level, and the C-train service on the lower level. The upper level is feasible for both APGs and PSDs. There are two ceiling mounted signals located at the center of each platform edge which would require relocation to implement a full height PSD system. Platform edge reconstruction would be required to support the requirements of an APG and PSD system (see Appendix B). Existing power is adequate.*

The lower level is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at the platform stairs as the remaining width would be 33" (see figure 1).

Description

The Nostrand Avenue Station is a below-grade station with two levels of straight side platforms **(see Figure 1).** The upper level services the express ‘A’ service and the lower level services the local ‘C’ service. This report focuses on the feasible upper level. The platform structures are cast-in-place concrete. There are columns evenly distributed along the platform edge measuring 3’-8” from the platform edge. The platform widths are approximately 24’-0” throughout. Ceiling heights measure no less than 7’-6” throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the southbound platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27’-6” x 7’-0”.

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

Tier 2-3 Report on Feasibility of Platform Edge Barriers for 'A' & 'C' Line Stations
(Nostrand Avenue Station)

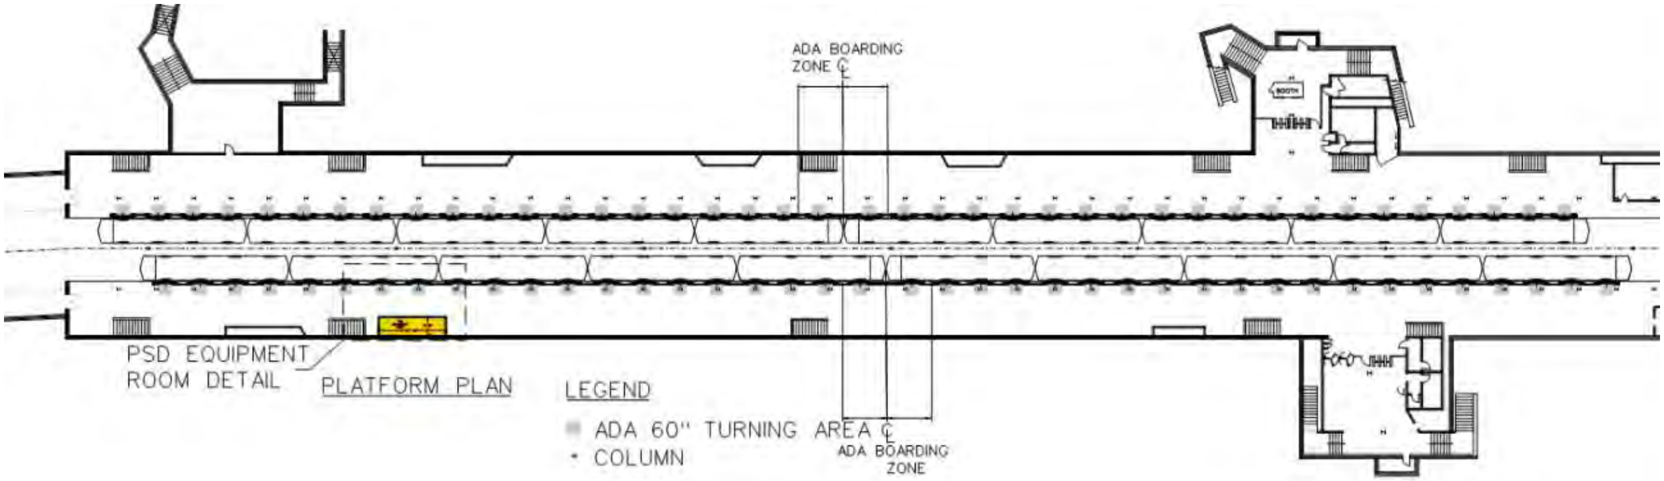

***Figure 1** – Overall plan – Upper level A-Train platform*
Nostrand Avenue Station

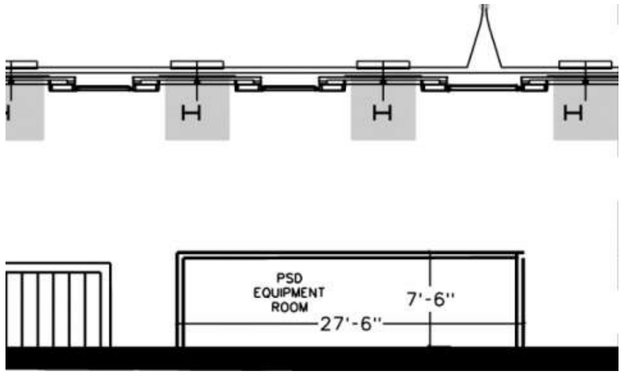

***Figure 2** – PSD Equipment Room Detail*
Nostrand Avenue Station

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of a APG/PSD system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Nostrand Avenue
Peak Demand Load from ConEd Report, (kW)	69.2

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.1M to install APGs and $43.3M to install PSDs (See Appendix E).

Table of Contents

1.36-C – MR 179 | Nostrand Avenue Station (Lower level)

Summary: *Nostrand Avenue Station is a two-level station, with the A-train service on the upper level, and the C-train service on the lower level. The upper level is feasible for both APGs and PSDs (see prior report).*

The lower level is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA complaint wheelchair movement would not be met at the platform stairs as the remaining width would be 33" (see figure 1).

The Nostrand Avenue Station is a below-grade station with two levels of straight side platforms. The upper level services the express 'A' service and the lower level services the local 'C' service. This report focuses on the infeasible lower level. The platforms do not have columns. There are five sets of stairs on each platform placed at 4'-0" from the platform edge. The implementation of a platform edge barrier would reduce the currently compliant width of 48" to 33" or less* which would not allow for an ADA-compliant corridor width of 36" for wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
Nostrand Avenue Station – lower level C-train platform

1.37 – MR 180 | Kingston Throop Avenue Station

Summary: *Kingston Throop Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both APG and PSD systems (see Appendix B). Existing power is adequate.*

Description

The Kingston Throop Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns on the platforms. The platform widths are approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the north end of the northbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

Kingston Throop Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.6M to install APGs and $40.0M to install PSDs (See Appendix E).

1.38 – MR 181 | Utica Avenue Station

Summary: *Utica Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). There are four ceiling mounted signals located at the platform edges which would require relocation to implement a full height PSD system. Existing power is adequate.*

Description

Utica Avenue Station is a below-grade station with two center / island platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly in two rows and measure 4'-3" from the platform edge. The platform widths vary from approximately 17'-8" to 27'-8". Ceiling heights measure no less than 7'-6" throughout. Two signals on each of the express platform edges will require relocation for the installation of a full-height PSD.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the lower station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are mildly curved. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

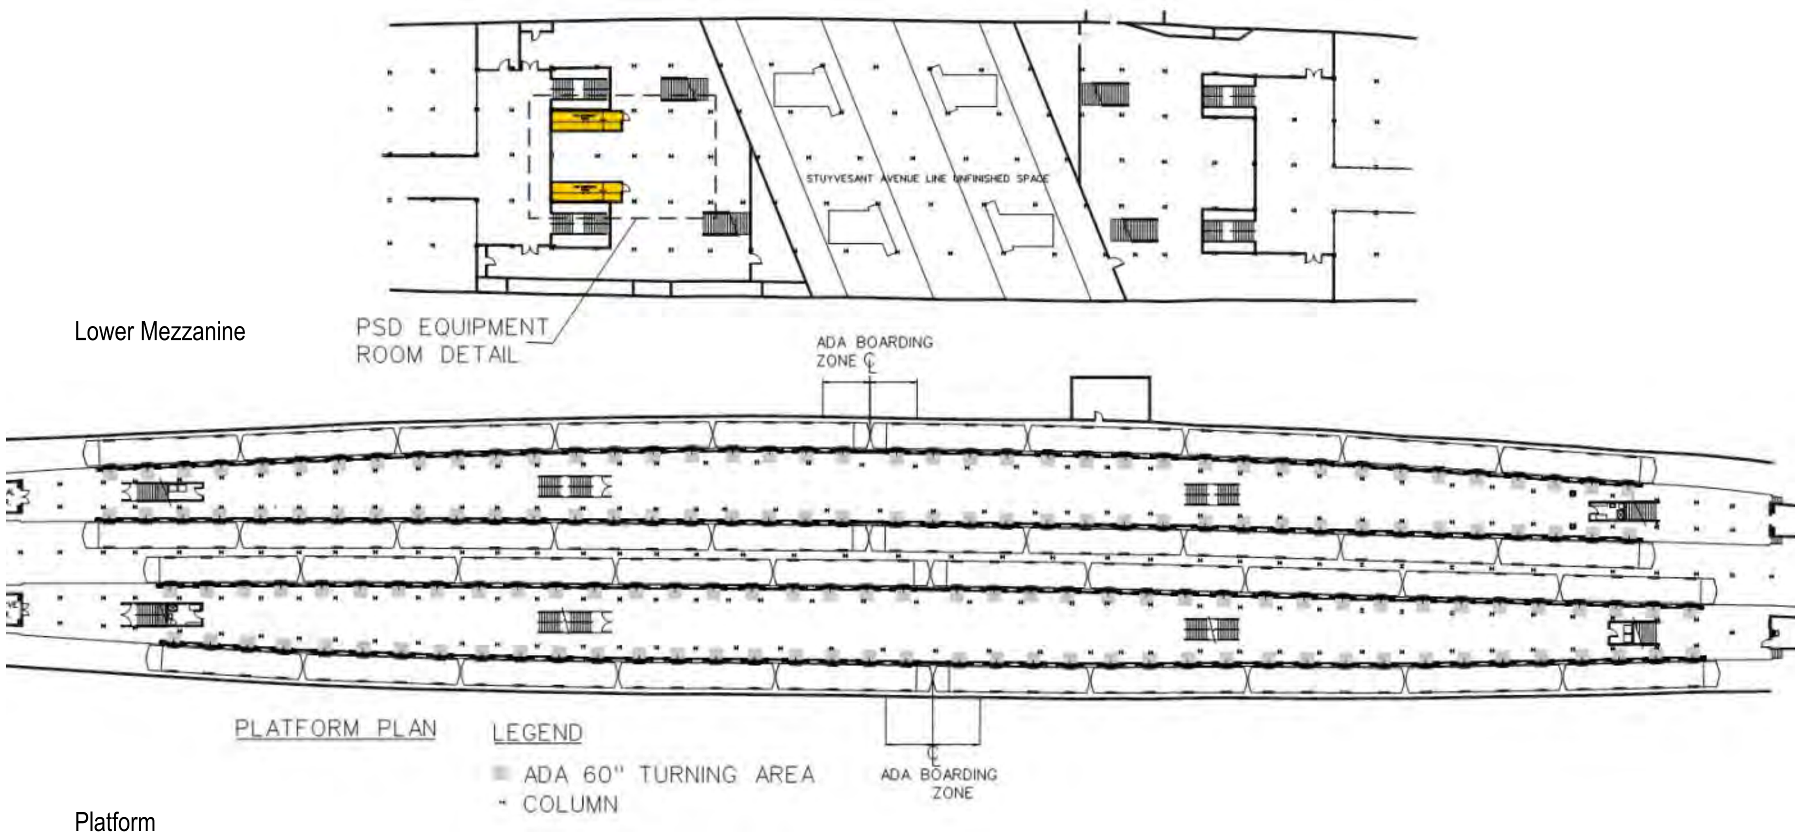

***Figure 1** – Overall Station Plan*
Utica Avenue Station

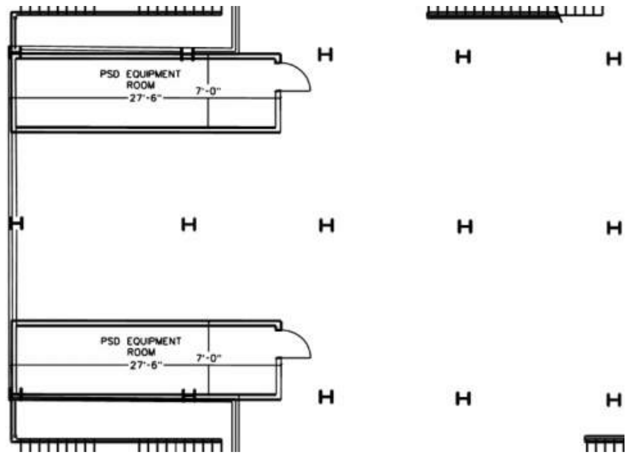

Figure 2 *– PSD Equipment Room Detail*
Utica Avenue Station- lower mezzanine

Platform obstructions within 5' of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60" circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $31.1M to install APGs and $39.5M to install PSDs. The cost of installation for the C-train for this station is estimated to be $31.1M to install APGs and $39.5M to install PSDs (See Appendix E).

1.39 – MR 182 | Ralph Avenue Station

Summary: *Ralph Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both APG and PSD systems (see Appendix B). Existing power is adequate.*

Description

The Ralph Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station mezzanine (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $31.5M to install APGs and $39.9M to install PSDs (See Appendix E).

1.40 – MR 183 | Rockaway Avenue Station

Summary: *Rockaway Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both APG and PSD systems (see Appendix B). Existing power is adequate.*

Description

The Rockaway Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platforms. The platform widths measure approximately 9'-4" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located at the edge of the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

***Figure 3** – General platform view*
Rockaway Avenue Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $32.8M to install APGs and $42.1M to install PSDs (See Appendix E).

1.41 – MR 184 | Broadway Junction Station

Summary: *Broadway Junction Station is feasible for both APGs and PSDs. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). There are four ceiling mounted signals located at the platform edges which would require relocation to implement a full height PSD system. Existing power is adequate.*

Description

Broadway Junction Station is a below-grade station with two center / island platforms (**see Figure 1)**. The platform structures are cast-in-place concrete. Columns are distributed evenly along two rows on each platform and measure 4'-2" from the platform edge. The platform widths vary from approximately 17'-8" to 21'-6". Ceiling heights measure no less than 7'-6" throughout. There are two signals above the edges of each express platform which will require relocation for the installation of full-height PSDs.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*: This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to be in coordination with existing or replacement lighting.

Equipment Room

The two equipment rooms can be located at the center of each platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Therefore, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant from the train doors to create gaps that would have to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges were reconstructed within the past thirty years. From our limited visual inspection and our knowledge of repair strategies used in station rehabilitations over the last thirty years, structural work would at a minimum be required for the installation of an APG system.

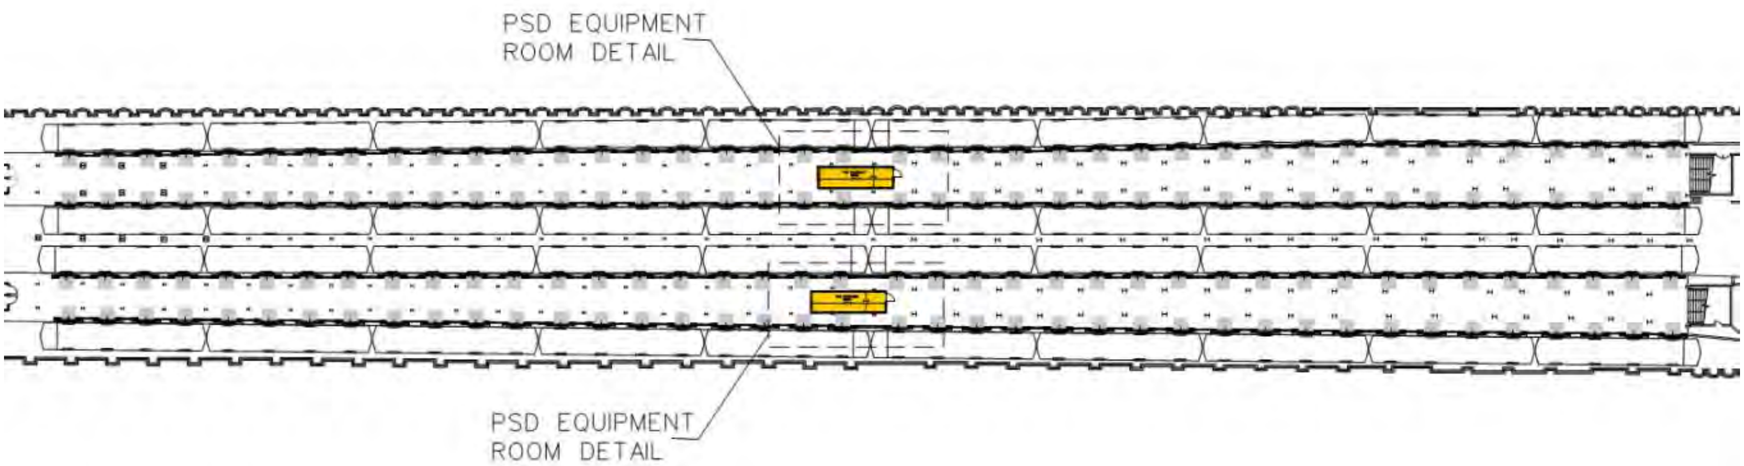

Figure 1 – Overall Station Plan
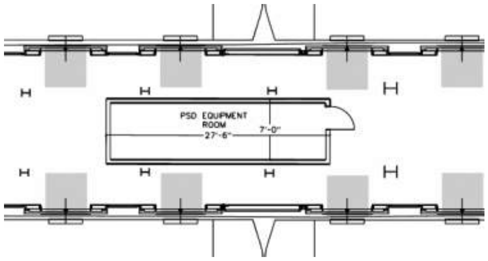
Broadway Junction Station

Tier 2-3 Report on Feasibility of Platform Edge Barriers for ‘A’ & ‘C’ Line Stations
(Broadway Junction Station)



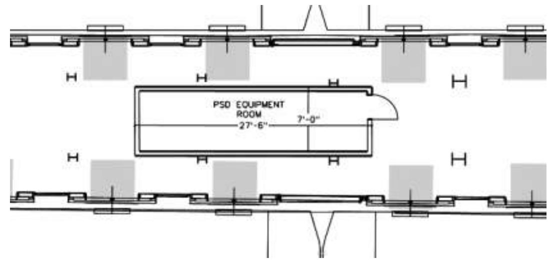


***Figure 2** & 3– PSD Equipment Room Detail*
Broadway Junction Station

Platform obstructions within 5’ of edge:

Southbound Track:

- Columns

Northbound Track:

- Columns

These obstructions do not present an impediment to the installation of PSDs.

Please note that in the ADA boarding zones, existing columns obstruct the 60” circle requirement discussed in the ADA summary in Appendix A. The installation of a PSD system would not further exacerbate these conditions.

Lighting:

Existing lighting: Throughout both platforms there are linear florescent fixtures mounted parallel to the platform edge. Depending on the specific APG/PSD design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG/PSD system. We do not consider a lack of adequate existing power to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.
Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Broadway Jct. / East NY
Peak Demand Load from ConEd Report, (kW)	128.8
Apparent Power (kVA)	161.0
Station Peak Demand Load, Max Current, (A)	447.2
Maximum Amount of Doors	160.0
PSD Total Load Including All Miscellaneous Loads, (A)	340.6
Total Load (Station Peak + PSD), (A)	788
Station Service Power Capacity, (A)	1000
Service Spare Capacity, (A)	212
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram & field survey, having 1000A Service. Station has (2) separate meters for each Normal & Reserve service. However, demand readings are combine for both Normal & Reserve.

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The cost of installation for the A-train for this station is estimated to be $31.0M to install APGs and $39.5M to install PSDs. The cost of installation for the C-train for this station is estimated to be $31.0M to install APGs and $39.5M to install PSDs (See Appendix E)

1.42 – MR 185 | Liberty Avenue Station

Summary: *Liberty Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of both APG and PSD systems (see Appendix B). Existing power is adequate.*

Description

The Liberty Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of both APG and PSD systems.

The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $30.9M to install APGs and $38.9M to install PSDs (See Appendix E).

1.43 – MR 186 | Van Siclen Avenue Station

Summary: *Van Siclen Avenue Station is feasible for both APGs and PSDs. Platform edge reconstruction would be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Van Siclen Avenue Station is a below-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths measure approximately 9'-8" throughout. Ceiling heights measure no less than 7'-6" throughout.

Full Height PSDs: Full height PSDs will require lateral structural bracing to the station ceiling as well as reconfiguration of existing ceiling-mounted systems to address edge-of-platform requirements of lighting, entrapment prevention sensors, CCTV, and standard NYCT wayfinding signage.

***Half Height PSDs (aka APGs)*:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting.

Equipment Room

The equipment room can be located in the station mezzanine (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

1.45 – MR 188 | Euclid Avenue Station

Summary: *Euclid Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" minimum pinch point requirement for ADA compliant wheelchair movement would not be met on the northbound platform as the remaining width would be 29" (see figure 1).*

Description

Euclid Avenue Station is a below-grade station with two straight center / island platforms. The platform structures are cast-in-place concrete. The platform widths vary from 9'-8" to 16'-10". The platforms are slightly bowed with two rows of columns approximately 3'-8" from edge of platform. At staircase P4, the columns measure 3'-8" from the platform edge and 1'-4" from the stair railing wall. The implementation of a platform edge barrier would reduce the currently compliant width of 44" to 29" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

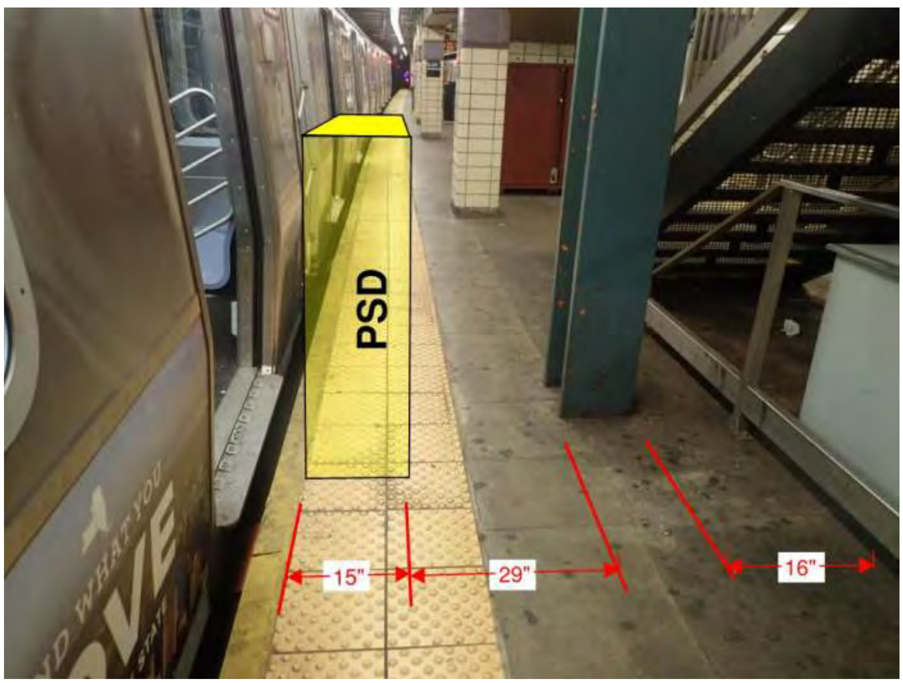

Figure 1 – Non-Compliant ADA condition
Euclid Avenue

1.46 – MR 189 | Grant Avenue Station

Summary: *Grant Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 21" (see figure 1).*

Description

Grant Avenue Station is a below-grade station with one straight center / island platform. The platform structures are cast-in-place concrete. The platform width is approximately 18'-0" throughout. There are two rows of columns measuring approximately 3'-0" from the platform edges. At the platform staircases, the columns measure 3'-0" from the platform edge and 2'-2" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 36" to 21" or less* which would not allow for ADA compliant wheelchair movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Grant Avenue

1.47 – MR 190 | 80th Street Station

Summary: *80th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 31" (see figure 1).*

Description

80th Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms are 11'-2" throughout. The stair railings are approximately 3'-10" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum corridor requirement of 36". The remaining 31" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
80th Street

1.48 – MR 191 | 88th Avenue Station

Summary: *88th Avenue Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

88th Avenue Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is 12'-2" throughout. The stair railings are approximately 4'-0" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum corridor requirement of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

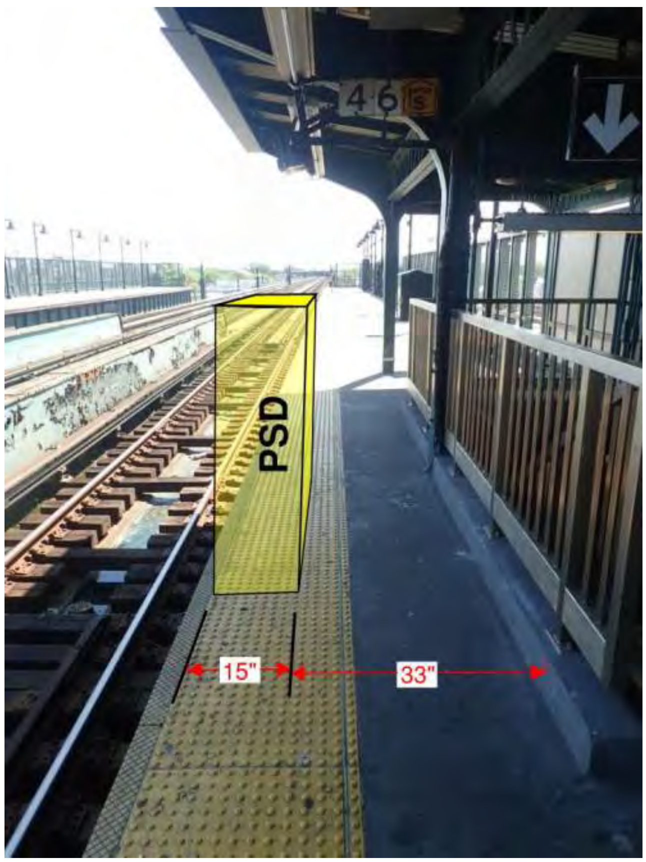

Figure 1 – Non-Compliant ADA condition
88th Avenue

1.49 – MR 192 | Rockaway Boulevard Station

Summary: *Rockaway Boulevard Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

Rockaway Boulevard Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is 10'-10" throughout. The stair railings are approximately 3'-8" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum corridor requirement of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

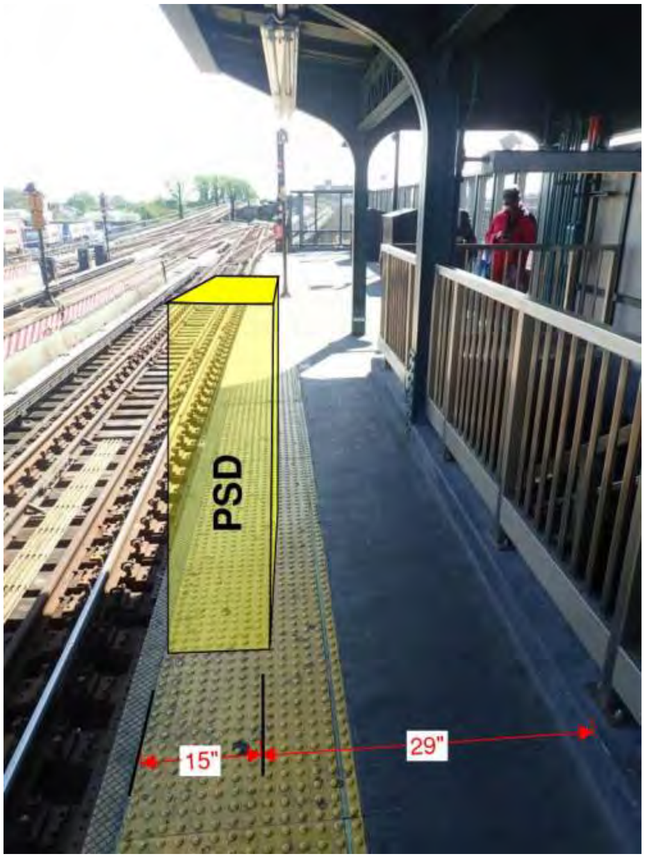

Figure 1 – Non-Compliant ADA condition
Rockaway Boulevard

1.50 – MR 193 | 104th Street Station

Summary: *104th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 29" (see figure 1).*

Description

104th Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is 10'-10" throughout. The stair railings are approximately 3'-8" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum corridor requirement of 36". The remaining 29" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

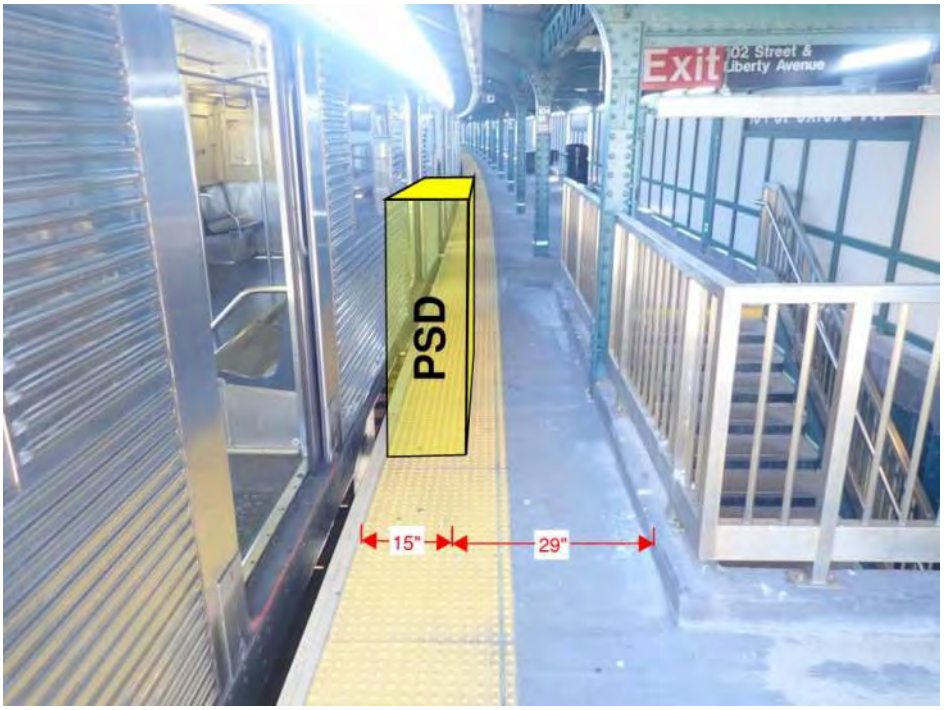

Figure 1 – Non-Compliant ADA condition

Table of Contents

1.51 – MR 194 | 111th Street Station

Summary: *111th Street Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 36" minimum corridor requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 33" (see figure 1).*

Description

111th Street Station is an elevated station with two straight side platforms. The platform structures are cast-in-place concrete. The width of the platforms is 11'-2" throughout. The stair railings are approximately 4'-0" from the platform edge. The implementation of a platform edge barrier would reduce this width below the required minimum corridor requirement of 36". The remaining 33" or less* would not allow for ADA compliant wheelchair movement nor passenger movement. See figure 1 for reference.

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

Figure 1 – Non-Compliant ADA condition
111th Street

Table of Contents

1.52 – MR 195 | Lefferts Boulevard Station

Summary: *Lefferts Boulevard Station is not feasible for both APGs and PSDs as their implementation would result in non-compliant ADA conditions. In the implementation of a platform edge barrier, the 32" pinch point requirement for ADA compliant wheelchair movement would not be met as the remaining width would be 17" (see figure 1).*

Description

Lefferts Boulevard Station is an elevated station with one nearly straight center / island platform. The platform structure is cast-in-place concrete. The platform width varies from 15'-0" to 20'-0". The platform is nearly straight with two rows of columns measuring approximately 2'-8" from the platform edges. At the platform staircases, the columns measure 2'-8" from the platform edge and 0'-10" from the staircase. The implementation of a platform edge barrier would reduce the currently compliant width of 32" to 17" or less* which would not allow for ADA compliant wheelchair movement nor regular passenger movement. See figure 1 for reference

*Please note that the ADA clearance measurements are subject to a slight decrease due to the required placement of PSD/APG equipment outside the Limiting line of line equipment (LLLE), which is dictated by the dynamic envelope of the trains.

***Figure 1** – Non-Compliant ADA condition*
Lefferts Boulevard

1.53 – MR 196 | Aqueduct Racetrack Station

Summary: *Aqueduct Racetrack Station is feasible for APGs only. Due to a lack of overhead structure at most of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power capacity could not be ascertained due to inaccessibility during survey. However, a lack of adequate existing power is not considered to be a determining factor of future feasibility.*

Description

The Aqueduct Racetrack Station is an on-grade station with one straight side platform **(see Figure 1)**. The platform structure is cast-in-place concrete. There are no columns throughout the platform. The platform width varies from 13'-8" to 43'-8". Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 50% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 50% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the back of the station platform (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edge is original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would be required for the installation of an APG system.

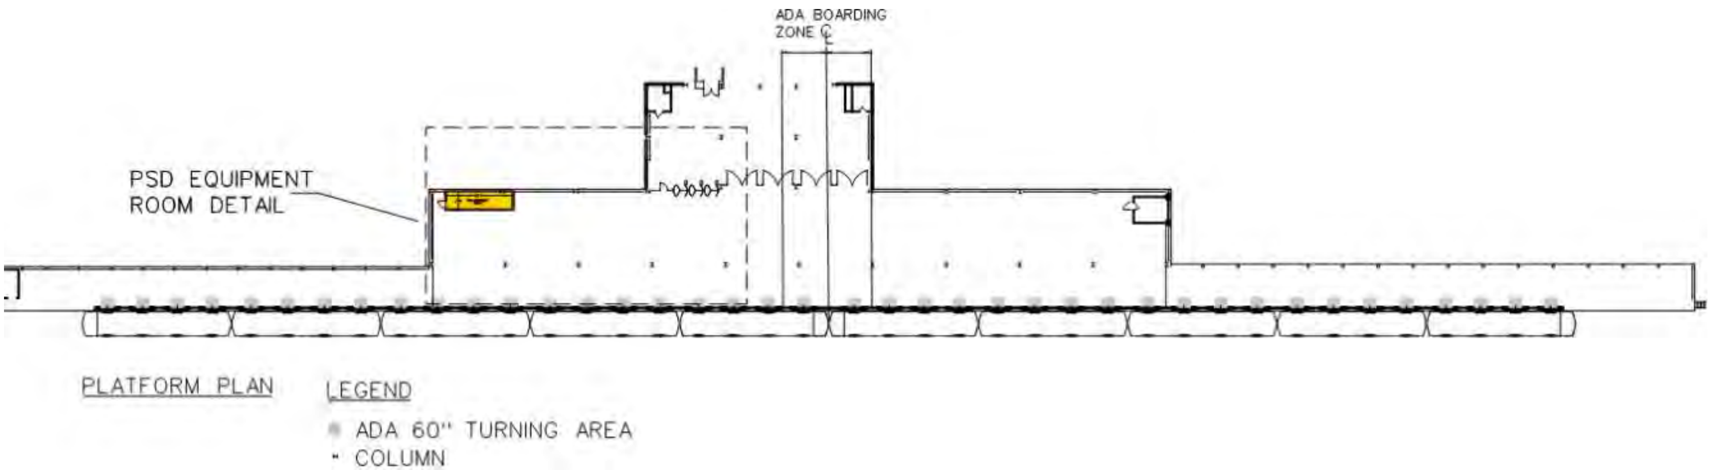

Figure 1 *– Overall plan*
Aqueduct Racetrack Station

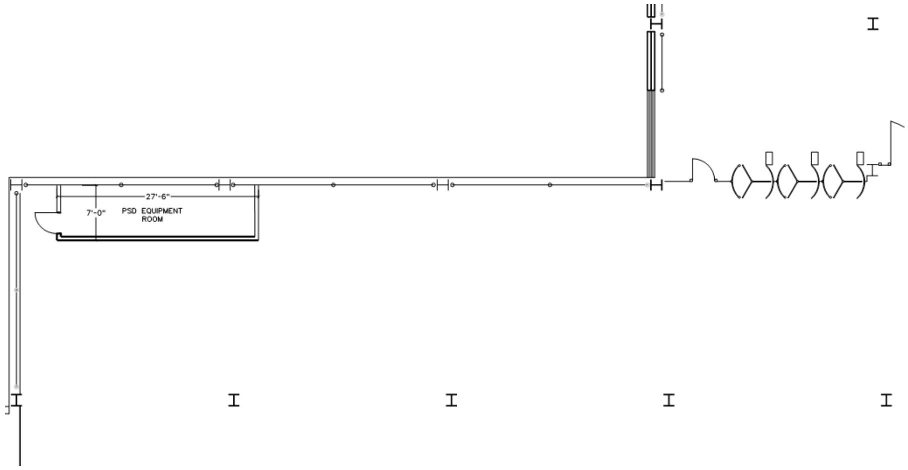

***Figure 1** – Equipment Room plan*
Aqueduct Racetrack Station

Platform obstructions within 5’ of edge:

Northbound Track:

- None

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the back of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

An analysis of adequate electrical power at this station could not be performed due to inaccessibility during survey. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project.

Figure 3 *– General platform view*
Aqueduct Racetrack Station

Historic Restrictions:
None

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $22.3M to install APGs (See Appendix E).

1.54 – MR 197 | Aqueduct North Conduit Station

Summary: *Aqueduct North Conduit Station is feasible for APGs only. Due to a lack of overhead structure at most of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Aqueduct North Conduit Station is an on-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform width is 11'-0" throughout. Ceiling heights measure no less than 7'-6" at the canopies. The canopy only covers 20% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 80% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located at the far north end of the northbound platform (**see Figure 1, Figure 2**). The proposed room dimensions are 27'-6" x 7'-0".

Track Layout

Tracks are tangent. Thus, we are not expecting that gaps between the platform and train will exacerbate the gap between the train doors and the PSDs. However, per NYCT standards, the Limiting Line of Line Equipment (LLLE) would necessitate the placement of PSDs sufficiently distant to create gaps that would need to be addressed by entrapment prevention measures.

Platform Edge Condition

The platform edges are original to the station construction. From our limited visual inspection and our knowledge of the original construction, reconstruction of the platform edge would at a minimum be required for the installation of a APG system.

Platform obstructions within 5' of edge:

Southbound Track:

- None

Northbound Track:

- None

Lighting:

Existing lighting: At the canopy there are linear florescent fixtures mounted parallel to the platform edge. Beyond the canopy are individual point source fixtures mounted at the back of the platform. Depending on the specific APG design used, there could be no or minimal alterations to the existing lighting configuration.

Power:

This station has adequate capacity to support the implementation of an APG system. Please note, a lack of adequate existing power is not considered to be a determining factor of future feasibility. If in the future, a PSD/APG project is to be implemented at this station, and it is determined at that time that an upgrade in power service to the station is required, it would simply mean an increased cost to the project. Below in Tables 1 & 2 please see the Power Capacity Analysis for this station.

Station Power Capacity Analysis (Normal Service)

Station Name	Aqueduct North Conduit Ave
Peak Demand Load from ConEd Report, (kW)	32.0
Apparent Power (kVA)	40.0
Station Peak Demand Load, Max Current, (A)	111.1
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	306
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	494
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service.

Table 1. Power Capacity Analysis

Station Power Capacity Analysis (Reserve Service)

Station Name	Aqueduct North Conduit Ave
Peak Demand Load from ConEd Report, (kW)	0.8
Apparent Power (kVA)	1.0
Station Peak Demand Load, Max Current, (A)	2.8
Maximum Amount of Doors	80.0
PSD Total Load Including All Miscellaneous Loads, (A)	194.6
Total Load (Station Peak + PSD), (A)	198
Station Service Power Capacity, (A)	800
Service Spare Capacity, (A)	603
Is Electrical Service Adequate?	**Yes**
Notes	Service rating is based on the 1 line diagram& field survey, having 800A fuses at Service switch. Station has (2) separate meter readings, for each Normal & Reserve service.

Rough Order-of-Magnitude Cost Estimate:
The rough order-of-magnitude (ROM) cost estimate is based on a summary of anticipated costs developed through a review of field conditions, analysis of space constraints and existing documentation. It is not based upon an actual conceptual design. The basis of estimate assumptions are listed in the attached ROM estimate. The total cost for this station is estimated to be $35.6M to install APGs (See Appendix E).

1.55 – MR 198 | Howard Beach - Airtrain Station

Summary: *Howard Beach - Airtrain Station is feasible for APGs only. Due to a lack of overhead structure at much of the platform, the full-height PSDs are not feasible. Platform edge reconstruction may be required to support the requirements of an APG system (see Appendix B). Existing power is adequate.*

Description

The Howard Beach - Airtrain Station is an on-grade station with two straight side platforms **(see Figure 1)**. The platform structures are cast-in-place concrete. There are no columns throughout the platform. The platform widths are 11'-4" throughout. Ceiling heights measure no less than 7'-6" at the canopy. The canopy only covers 50% of the platform length.

Full Height PSDs: Full height PSDs are not feasible due to the lack of overhead structure at 50% of the station platform length. Full height PSDs require a top connection to brace against wind load.

Half Height PSDs (aka APGs)**:** This system is less likely to affect existing lighting and other systems on the ceiling. Depending on the half height PSD design, sensors may be ceiling-mounted or mounted on the APG unit itself. In any case, there will be a CCTV camera over each motorized sliding door which will need to coordination with existing or replacement lighting. At portions of platforms without roof, a custom-designed CCTV camera will need to be developed to be integrated into the APG housing.

Equipment Room

The equipment room can be located on grade beyond the north end of the northbound platform. (**see Figure 1, Figure 2)**. The proposed room dimensions are 27'-6" x 7'-0".
